A hint that tells the scheduler to prefer scheduling a task on the local thread number associated with this hint. Local thread numbers are indexed from zero. It is up to the scheduler to decide how to interpret thread numbers that are larger than the number of threads available to the scheduler. Typically thread numbers will wrap around when too large.

numa = 2
A hint that tells the scheduler to prefer scheduling a task on the NUMA domain associated with this hint. NUMA domains are indexed from zero. It is up to the scheduler to decide how to interpret NUMA domain indices that are larger than the number of available NUMA domains to the scheduler. Typically indices will wrap around when too large.

Functions

std::ostream &**operator<<** (*std*::ostream &*os*, *thread_schedule_state* **const** *t*)

char **const** ***get_thread_state_name** (*thread_schedule_state state*)
Returns the name of the given state.

Get the readable string representing the name of the given thread_state constant.

Parameters
- `state`: this represents the thread state.

std::ostream &**operator<<** (*std*::ostream &*os*, *thread_priority* **const** *t*)

char **const** ***get_thread_priority_name** (*thread_priority priority*)
Return the thread priority name.

Get the readable string representing the name of the given thread_priority constant.

Parameters
- `this`: represents the thread priority.

std::ostream &**operator<<** (*std*::ostream &*os*, *thread_restart_state* **const** *t*)

char **const** ***get_thread_state_ex_name** (*thread_restart_state state*)
Get the readable string representing the name of the given thread_restart_state constant.

char **const** ***get_thread_state_name** (thread_state *state*)
Get the readable string representing the name of the given thread_state constant.

std::ostream &**operator<<** (*std*::ostream &*os*, *thread_stacksize* **const** *t*)

char **const** ***get_stack_size_enum_name**(*thread_stacksize size*)

Returns the stack size name.

Get the readable string representing the given stack size constant.

Parameters

- `size`: this represents the stack size

struct thread_schedule_hint

#include <thread_enums.hpp> A hint given to a scheduler to guide where a task should be scheduled.

A scheduler is free to ignore the hint, or modify the hint to suit the resources available to the scheduler.

Public Functions

constexpr thread_schedule_hint()

Construct a default hint with mode thread_schedule_hint_mode::none.

constexpr thread_schedule_hint(*std*::int16_t *thread_hint*)

Construct a hint with mode thread_schedule_hint_mode::thread and the given hint as the local thread number.

constexpr thread_schedule_hint(*thread_schedule_hint_mode mode*, *std*::int16_t *hint*)

Construct a hint with the given mode and hint. The numerical hint is unused when the mode is thread_schedule_hint_mode::none.

Public Members

std::int16_t **hint**

The hint associated with the mode. The interepretation of this hint depends on the given mode.

thread_schedule_hint_mode **mode**

The mode of the scheduling hint.

namespace hpx

Enums

enum error

Possible error conditions.

This enumeration lists all possible error conditions which can be reported from any of the API functions.

Values:

success = 0
The operation was successful.

no_success = 1
The operation did failed, but not in an unexpected manner.

not_implemented = 2
The operation is not implemented.

out_of_memory = 3
The operation caused an out of memory condition.

bad_action_code = 4

bad_component_type = 5
The specified component type is not known or otherwise invalid.

network_error = 6
A generic network error occurred.

version_too_new = 7
The version of the network representation for this object is too new.

version_too_old = 8
The version of the network representation for this object is too old.

version_unknown = 9
The version of the network representation for this object is unknown.

unknown_component_address = 10

duplicate_component_address = 11
The given global id has already been registered.

invalid_status = 12
The operation was executed in an invalid status.

bad_parameter = 13
One of the supplied parameters is invalid.

internal_server_error = 14

service_unavailable = 15

bad_request = 16

repeated_request = 17

lock_error = 18

duplicate_console = 19
There is more than one console locality.

no_registered_console = 20
There is no registered console locality available.

startup_timed_out = 21

uninitialized_value = 22

bad_response_type = 23

deadlock = 24

assertion_failure = 25

null_thread_id = 26
Attempt to invoke a API function from a non-HPX thread.

invalid_data = 27

yield_aborted = 28
The yield operation was aborted.

dynamic_link_failure = 29

commandline_option_error = 30
One of the options given on the command line is erroneous.

serialization_error = 31
There was an error during serialization of this object.

unhandled_exception = 32
An unhandled exception has been caught.

kernel_error = 33
The OS kernel reported an error.

broken_task = 34
The task associated with this future object is not available anymore.

task_moved = 35
The task associated with this future object has been moved.

task_already_started = 36
The task associated with this future object has already been started.

future_already_retrieved = 37
The future object has already been retrieved.

promise_already_satisfied = 38
The value for this future object has already been set.

future_does_not_support_cancellation = 39
The future object does not support cancellation.

future_can_not_be_cancelled = 40
The future can't be canceled at this time.

no_state = 41
The future object has no valid shared state.

broken_promise = 42
The promise has been deleted.

thread_resource_error = 43

future_cancelled = 44

thread_cancelled = 45

thread_not_interruptable = 46

duplicate_component_id = 47
The component type has already been registered.

unknown_error = 48
An unknown error occurred.

bad_plugin_type = 49
The specified plugin type is not known or otherwise invalid.

filesystem_error = 50
The specified file does not exist or other filesystem related error.

bad_function_call = 51
equivalent of std::bad_function_call

task_canceled_exception = 52
parallel::v2::task_canceled_exception

task_block_not_active = 53
task_region is not active

out_of_range = 54
Equivalent to std::out_of_range.

length_error = 55
Equivalent to std::length_error.

migration_needs_retry = 56
migration failed because of global race, retry

namespace hpx

Unnamed Group

error_code **make_error_code**(*error e*, *throwmode mode* = *throwmode*::plain)
Returns a new *error_code* constructed from the given parameters.

error_code **make_error_code**(*error e*, char **const** **func*, char **const** **file*, long *line*, *throwmode mode* = *throwmode*::plain)

error_code **make_error_code**(*error e*, char **const** **msg*, *throwmode mode* = *throwmode*::plain)
Returns error_code(e, msg, mode).

error_code **make_error_code**(*error e*, char **const** **msg*, char **const** **func*, char **const** **file*, long *line*, *throwmode mode* = *throwmode*::plain)

error_code **make_error_code**(*error e*, *std*::string **const** &*msg*, *throwmode mode* = *throwmode*::plain)

Returns error_code(e, msg, mode).

error_code **make_error_code**(*error e*, *std*::string **const** &*msg*, char **const** **func*, char **const** **file*, long *line*, *throwmode mode* = *throwmode*::plain)

error_code **make_error_code**(*std*::exception_ptr **const** &*e*)

Functions

std::error_category **const** &**get_hpx_category**()

Returns generic HPX error category used for new errors.

std::error_category **const** &**get_hpx_rethrow_category**()

Returns generic HPX error category used for errors re-thrown after the exception has been de-serialized.

error_code **make_success_code**(*throwmode mode* = *throwmode*::plain)

Returns *error_code*(hpx::success, "success", mode).

class error_code : **public** *error_code*

#include <error_code.hpp> A *hpx::error_code* represents an arbitrary error condition.

The class *hpx::error_code* describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

Note Class *hpx::error_code* is an adjunct to error reporting by exception

Public Functions

error_code(*throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `nothing`:

error_code(*error e*, *throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `nothing`:

error_code(*error e*, char **const** **func*, char **const** **file*, long *line*, *throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `func`: The name of the function where the error was raised.
- `file`: The file name of the code where the error was raised.
- `line`: The line number of the code line where the error was raised.
- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `nothing`:

error_code(*error e*, char **const** **msg*, *throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `msg`: The parameter `msg` holds the error message the new exception should encapsulate.
- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `std::bad_alloc`: (if allocation of a copy of the passed string fails).

error_code(*error e*, char **const** **msg*, char **const** **func*, char **const** **file*, long *line*, *throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `msg`: The parameter `msg` holds the error message the new exception should encapsulate.
- `func`: The name of the function where the error was raised.
- `file`: The file name of the code where the error was raised.
- `line`: The line number of the code line where the error was raised.
- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `std::bad_alloc`: (if allocation of a copy of the passed string fails).

error_code(*error e*, *std*::string **const** &*msg*, *throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `msg`: The parameter `msg` holds the error message the new exception should encapsulate.
- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `std::bad_alloc`: (if allocation of a copy of the passed string fails).

error_code(*error e*, *std*::string **const** &*msg*, char **const** **func*, char **const** **file*, long *line*, *throwmode mode* = *throwmode*::plain)

Construct an object of type *error_code*.

Parameters

- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `msg`: The parameter `msg` holds the error message the new exception should encapsulate.
- `func`: The name of the function where the error was raised.
- `file`: The file name of the code where the error was raised.
- `line`: The line number of the code line where the error was raised.
- `mode`: The parameter `mode` specifies whether the constructed *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

Exceptions

- `std::bad_alloc`: (if allocation of a copy of the passed string fails).

std::string **get_message**() **const**

Return a reference to the error message stored in the *hpx::error_code*.

Exceptions

- `nothing`:

void **clear**()

Clear this *error_code* object. The postconditions of invoking this method are.

- value() == hpx::success and category() == *hpx::get_hpx_category()*

error_code(*error_code* **const** &*rhs*)

Copy constructor for *error_code*

Note This function maintains the error category of the left hand side if the right hand side is a success code.

error_code &**operator=**(*error_code* **const** &*rhs*)

Assignment operator for *error_code*

Note This function maintains the error category of the left hand side if the right hand side is a success code.

using custom_exception_info_handler_type = *std*::function<*hpx*::*exception_info*(*std*::string **const**&, *std*::string **const**&, long, *std*::string **const**&)>

using pre_exception_handler_type = *std*::function<void()>

Functions

void **set_custom_exception_info_handler**(*custom_exception_info_handler_type f*)

void **set_pre_exception_handler**(*pre_exception_handler_type f*)

std::string **get_error_what**(*exception_info* **const** &*xi*)

Return the error message of the thrown exception.

The function *hpx::get_error_what* can be used to extract the diagnostic information element representing the error message as stored in the given exception instance.

Return The error message stored in the exception If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, hpx::get_error() *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

error **get_error** (*hpx*::*exception* **const** &*e*)

Return the error code value of the exception thrown.

The function *hpx::get_error* can be used to extract the diagnostic information element representing the error value code as stored in the given exception instance.

Return The error value code of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return *hpx::naming::invalid_locality_id*.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, hpx::get_error_what(), *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `e`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception, hpx::error_code, or *std::exception_ptr*.

Exceptions

- `nothing`:

error **get_error** (*hpx*::*error_code* **const** &*e*)

std::string **get_error_function_name** (*hpx*::*exception_info* **const** &*xi*)

Return the function name from which the exception was thrown.

The function *hpx::get_error_function_name* can be used to extract the diagnostic information element representing the name of the function as stored in the given exception instance.

Return The name of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()* hpx::get_error_file_name(), hpx::get_error_line_number(), *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, hpx::get_error(), *hpx::get_error_backtrace()*, *hpx::get_error_env()*, hpx::get_error_what(), *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

std::string **get_error_file_name** (*hpx*::*exception_info* **const** &*xi*)

Return the (source code) file name of the function from which the exception was thrown.

The function *hpx::get_error_file_name* can be used to extract the diagnostic information element representing the name of the source file as stored in the given exception instance.

Return The name of the source file of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, hpx::get_error_function_name(), hpx::get_error_line_number(), *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, hpx::get_error(), *hpx::get_error_backtrace()*, *hpx::get_error_env()*, hpx::get_error_what(), *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

long **`get_error_line_number`**(*hpx::exception_info* **const** &*xi*)

Return the line number in the (source code) file of the function from which the exception was thrown.

The function *hpx::get_error_line_number* can be used to extract the diagnostic information element representing the line number as stored in the given exception instance.

Return The line number of the place where the exception was thrown. If the exception instance does not hold this information, the function will return -1.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, hpx::get_error_function_name(), hpx::get_error_file_name() *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, hpx::get_error(), *hpx::get_error_backtrace()*, *hpx::get_error_env()*, hpx::get_error_what(), *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, *std::exception*, or *std::exception_ptr*.

Exceptions

- `nothing`:

`class exception` : **`public`** system_error

#include <exception.hpp> A *hpx::exception* is the main exception type used by HPX to report errors.

The *hpx::exception* type is the main exception type used by HPX to report errors. Any exceptions thrown by functions in the HPX library are either of this type or of a type derived from it. This implies that it is always safe to use this type only in catch statements guarding HPX library calls.

Subclassed by *hpx::exception_list*

Public Functions

exception(*error e = success*)
Construct a *hpx::exception* from a *hpx::error*.

Parameters
- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.

exception(*std*::system_error **const** &*e*)
Construct a *hpx::exception* from a boost::system_error.

exception(*std*::error_code **const** &*e*)
Construct a *hpx::exception* from a boost::system::error_code (this is new for Boost V1.69). This constructor is required to compensate for the changes introduced as a resolution to LWG3162 (https://cplusplus.github.io/LWG/issue3162).

exception(*error e*, char **const** **msg*, *throwmode mode = throwmode*::plain)
Construct a *hpx::exception* from a *hpx::error* and an error message.

Parameters
- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `msg`: The parameter `msg` holds the error message the new exception should encapsulate.
- `mode`: The parameter `mode` specifies whether the returned *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

exception(*error e*, *std*::string **const** &*msg*, *throwmode mode = throwmode*::plain)
Construct a *hpx::exception* from a *hpx::error* and an error message.

Parameters
- `e`: The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `msg`: The parameter `msg` holds the error message the new exception should encapsulate.
- `mode`: The parameter `mode` specifies whether the returned *hpx::error_code* belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

~exception()
Destruct a *hpx::exception*

Exceptions
- `nothing`:

error **get_error**() **const**
The function get_error() returns the hpx::error code stored in the referenced instance of a *hpx::exception*. It returns the hpx::error code this exception instance was constructed from.

Exceptions
- `nothing`:

error_code **get_error_code**(*throwmode mode = throwmode*::plain) **const**
The function get_error_code() returns a *hpx::error_code* which represents the same error condition as this *hpx::exception* instance.

Parameters

- `mode`: The parameter `mode` specifies whether the returned *hpx::error_code* belongs to the error category *hpx_category* (if mode is *throwmode::plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

struct thread_interrupted : **public** *exception*

#include <exception.hpp> A *hpx::thread_interrupted* is the exception type used by HPX to interrupt a running HPX thread.

The hpx::thread_interrupted type is the exception type used by HPX to interrupt a running thread.

A running thread can be interrupted by invoking the interrupt() member function of the corresponding hpx::thread object. When the interrupted thread next executes one of the specified interruption points (or if it is currently blocked whilst executing one) with interruption enabled, then a *hpx::thread_interrupted* exception will be thrown in the interrupted thread. If not caught, this will cause the execution of the interrupted thread to terminate. As with any other exception, the stack will be unwound, and destructors for objects of automatic storage duration will be executed.

If a thread wishes to avoid being interrupted, it can create an instance of *hpx::this_thread::disable_interruption*. Objects of this class disable interruption for the thread that created them on construction, and restore the interruption state to whatever it was before on destruction.

```
void f()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::disable_interruption di2;
            // interruption still disabled
        } // di2 destroyed, interruption state restored
        // interruption still disabled
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

The effects of an instance of *hpx::this_thread::disable_interruption* can be temporarily reversed by constructing an instance of *hpx::this_thread::restore_interruption*, passing in the *hpx::this_thread::disable_interruption* object in question. This will restore the interruption state to what it was when the *hpx::this_thread::disable_interruption* object was constructed, and then disable interruption again when the *hpx::this_thread::restore_interruption* object is destroyed.

```
void g()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::restore_interruption ri(di);
            // interruption now enabled
        } // ri destroyed, interruption disable again
    } // di destroyed, interruption state restored
```

(continues on next page)

(continued from previous page)

```
    // interruption now enabled
}
```

At any point, the interruption state for the current thread can be queried by calling *hpx::this_thread::interruption_enabled()*.

Defines

HPX_THROWMODE_UNSCOPED_ENUM_DEPRECATION_MSG

namespace hpx

Enums

enum throwmode

Encode error category for new *error_code*.

Values:

plain = 0

rethrow = 1

lightweight = 0x80

Functions

constexpr bool **operator&** (*throwmode lhs*, *throwmode rhs*)

Variables

constexpr *throwmode* **plain** = *throwmode*::plain

constexpr *throwmode* **rethrow** = *throwmode*::rethrow

constexpr *throwmode* **lightweight** = *throwmode*::lightweight

constexpr *throwmode* **lightweight_rethrow** = *throwmode*::lightweight_rethrow

error_code **throws**

Predefined *error_code* object used as "throw on error" tag.

The predefined *hpx::error_code* object *hpx::throws* is supplied for use as a "throw on error" tag.

Functions that specify an argument in the form '*error_code*& ec=throws' (with appropriate namespace qualifiers), have the following error handling semantics:

If &ec != &throws and an error occurred: ec.value() returns the implementation specific error number for the particular error that occurred and ec.category() returns the error_category for ec.value().

If &ec != &throws and an error did not occur, ec.clear().

If an error occurs and &ec == &throws, the function throws an exception of type hpx::exception or of a type derived from it. The exception's *get_errorcode()* member function returns a reference to an hpx::error_code object with the behavior as specified above.

namespace hpx

class exception_list : **public** *hpx*::*exception*
#include <exception_list.hpp> The class *exception_list* is a container of exception_ptr objects parallel algorithms may use to communicate uncaught exceptions encountered during parallel execution to the caller of the algorithm

The type exception_list::const_iterator fulfills the requirements of a forward iterator.

Public Types

using iterator = exception_list_type::const_iterator
bidirectional iterator

Public Functions

std::size_t **size**() **const**
The number of exception_ptr objects contained within the *exception_list*.

Note Complexity: Constant time.

exception_list_type::const_iterator **begin**() **const**
An iterator referring to the first exception_ptr object contained within the *exception_list*.

exception_list_type::const_iterator **end**() **const**
An iterator which is the past-the-end value for the *exception_list*.

Defines

HPX_THROW_EXCEPTION(*errcode*, *f*, ...)
Throw a *hpx::exception* initialized from the given parameters.

The macro *HPX_THROW_EXCEPTION* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the hpx::error code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_EXCEPTION(hpx::no_success, "raise_exception", "simulated error");
}
```

Example:

HPX_THROWS_IF(*ec*, *errcode*, *f*, ...)
Either throw a *hpx::exception* or initialize hpx::error_code from the given parameters.

The macro *HPX_THROWS_IF* can be used to either throw a hpx::exception or to initialize a hpx::error_code from the given parameters. If &ec == &hpx::throws, the semantics of this macro are equivalent to *HPX_THROW_EXCEPTION*. If &ec != &hpx::throws, the hpx::error_code instance `ec` is initialized instead.

The parameter `errcode` holds the hpx::error code from which the new exception should be initialized. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

namespace hpx

namespace execution

struct auto_chunk_size

#include <auto_chunk_size.hpp> Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

Public Functions

constexpr auto_chunk_size(*std*::uint64_t *num_iters_for_timing* = 0)

Construct an auto_chunk_size executor parameters object

Note Default constructed auto_chunk_size executor parameter types will use 80 microseconds as the minimal time for which any of the scheduled chunks should run.

auto_chunk_size(*hpx*::*chrono*::*steady_duration* **const** &*rel_time*, *std*::uint64_t *num_iters_for_timing* = 0)

Construct an auto_chunk_size executor parameters object

Parameters

- `rel_time`: [in] The time duration to use as the minimum to decide how many loop iterations should be combined.

namespace hpx

namespace execution

struct dynamic_chunk_size

#include <dynamic_chunk_size.hpp> Loop iterations are divided into pieces of size *chunk_size* and then dynamically scheduled among the threads; when a thread finishes one chunk, it is dynamically assigned another If *chunk_size* is not specified, the default chunk size is 1.

Note This executor parameters type is equivalent to OpenMP's DYNAMIC scheduling directive.

Public Functions

constexpr dynamic_chunk_size(*std*::size_t *chunk_size* = 1)

Construct a dynamic_chunk_size executor parameters object

Parameters

- `chunk_size`: [in] The optional chunk size to use as the number of loop iterations to schedule together. The default chunk size is 1.

namespace hpx

namespace parallel

namespace execution

Variables

hpx::*parallel*::*execution*::*has_pending_closures_t* **has_pending_closures**

hpx::*parallel*::*execution*::*get_pu_mask_t* **get_pu_mask**

hpx::*parallel*::*execution*::*set_scheduler_mode_t* **set_scheduler_mode**

struct get_pu_mask_t : **public** *hpx*::*functional*::detail::tag_fallback<*get_pu_mask_t*>

#include <*execution_information.hpp*> Retrieve the bitmask describing the processing units the given thread is allowed to run on

All threads::executors invoke sched.get_pu_mask().

Note If the executor does not support this operation, this call will always invoke hpx::threads::get_pu_mask()

Parameters

- `exec`: [in] The executor object to use for querying the number of pending tasks.
- `topo`: [in] The topology object to use to extract the requested information.
- `thream_num`: [in] The sequence number of the thread to retrieve information for.

Private Functions

template<typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*get_pu_mask_t*, *Executor*&&, *threads*::*topology* &*topo*, *std*::size_t *thread_num*)

template<typename **Executor**>
decltype(auto) **friend tag_invoke**(*get_pu_mask_t*, *Executor* &&*exec*, *threads*::*topology* &*topo*, *std*::size_t *thread_num*)

struct has_pending_closures_t : **public** *hpx*::*functional*::detail::tag_fallback<*has_pending_closures_t*>

#include <*execution_information.hpp*> Retrieve whether this executor has operations pending or not.

Note If the executor does not expose this information, this call will always return *false*

Parameters

- `exec`: [in] The executor object to use to extract the requested information for.

Private Functions

template<typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*has_pending_closures_t*, *Executor*&&)

template<typename **Executor**>
decltype(auto) **friend tag_invoke**(*has_pending_closures_t*, *Executor* &&*exec*)

struct set_scheduler_mode_t : **public** *hpx*::*functional*::detail::tag_fallback<*set_scheduler_mode_t*>

#include <*execution_information.hpp*> Set various modes of operation on the scheduler underneath the given executor.

Note This calls exec.set_scheduler_mode(mode) if it exists; otherwise it does nothing.

Parameters

- `exec`: [in] The executor object to use.
- `mode`: [in] The new mode for the scheduler to pick up

Friends

template<typename **Executor**, typename **Mode**>
void **tag_fallback_invoke**(set_scheduler_mode_t, *Executor*&&, *Mode* **const**&)

Private Functions

template<typename **Parameters**, typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*mark_end_execution_t*, *Parameters &&params*, *Executor &&exec*)

struct mark_end_of_scheduling_t : **public** *hpx*::*functional*::detail::tag_fallback<*mark_end_of_schedulin*
#include <execution_parameters_fwd.hpp> Mark the end of scheduling tasks during parallel algorithm execution

Note This calls params.mark_begin_execution(exec) if it exists; otherwise it does nothing.
Parameters
- `params`: [in] The executor parameters object to use as a fallback if the executor does not expose

Private Functions

template<typename **Parameters**, typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*mark_end_of_scheduling_t*, *Parameters &&params*, *Executor &&exec*)

struct maximal_number_of_chunks_t : **public** *hpx*::*functional*::detail::tag_fallback<*maximal_number_of*
#include <execution_parameters_fwd.hpp> Return the largest reasonable number of chunks to create for a single algorithm invocation.

Parameters
- `params`: [in] The executor parameters object to use for determining the number of chunks for the given number of *cores*.
- `exec`: [in] The executor object which will be used for scheduling of the loop iterations.
- `cores`: [in] The number of cores the number of chunks should be determined for.
- `num_tasks`: [in] The number of tasks the chunk size should be determined for

Private Functions

template<typename **Parameters**, typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*maximal_number_of_chunks_t*, *Parameters &&params*, *Executor &&exec*, *std*::size_t *cores*, *std*::size_t *num_tasks*)

struct processing_units_count_t : **public** *hpx*::*functional*::detail::tag_fallback<*processing_units_count*
#include <execution_parameters_fwd.hpp> Retrieve the number of (kernel-)threads used by the associated executor.

Note This calls params.processing_units_count(Executor&&) if it exists; otherwise it forwards the request to the executor parameters object.

Parameters

- `params`: [in] The executor parameters object to use as a fallback if the executor does not expose

Private Functions

template<typename **Parameters**, typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*processing_units_count_t*, *Parameters &&params*, *Executor &&exec*)

struct reset_thread_distribution_t : **public** *hpx*::*functional*::detail::tag_fallback<*reset_thread_distri*
#include <execution_parameters_fwd.hpp> Reset the internal round robin thread distribution scheme for the given executor.

Note This calls params.reset_thread_distribution(exec) if it exists; otherwise it does nothing.

Parameters

- `params`: [in] The executor parameters object to use for resetting the thread distribution scheme.
- `exec`: [in] The executor object to use.

Private Functions

template<typename **Parameters**, typename **Executor**>
decltype(auto) **friend tag_fallback_invoke**(*reset_thread_distribution_t*, *Parameters &&params*, *Executor &&exec*)

struct with_processing_units_count_t : **public** *hpx*::*functional*::detail::tag_fallback<*with_processing*
#include <execution_parameters_fwd.hpp> Generate a policy that supports setting the number of cores for execution.

namespace hpx

namespace execution

struct guided_chunk_size
#include <guided_chunk_size.hpp> Iterations are dynamically assigned to threads in blocks as threads request them until no blocks remain to be assigned. Similar to dynamic_chunk_size except that the

block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to *number_of_iterations* / *number_of_cores*. Subsequent blocks are proportional to *number_of_iterations_remaining* / *number_of_cores*. The optional chunk size parameter defines the minimum block size. The default chunk size is 1.

Note This executor parameters type is equivalent to OpenMP's GUIDED scheduling directive.

Public Functions

constexpr guided_chunk_size(*std*::size_t *min_chunk_size* = 1)

Construct a guided_chunk_size executor parameters object

Parameters

- `min_chunk_size`: [in] The optional minimal chunk size to use as the minimal number of loop iterations to schedule together. The default minimal chunk size is 1.

namespace hpx

namespace execution

struct num_cores

#include <num_cores.hpp> Control number of cores in executors which need a functionality for setting the number of cores to be used by an algorithm directly

Public Functions

constexpr num_cores(*std*::size_t *cores* = 1)

Construct a num_cores executor parameters object

Note make sure the minimal number of cores is 1

namespace hpx

namespace execution

struct persistent_auto_chunk_size

#include <persistent_auto_chunk_size.hpp> Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

Public Functions

constexpr persistent_auto_chunk_size(*std*::uint64_t *num_iters_for_timing* = 0)
Construct an persistent_auto_chunk_size executor parameters object

Note Default constructed persistent_auto_chunk_size executor parameter types will use 0 microseconds as the execution time for each chunk and 80 microseconds as the minimal time for which any of the scheduled chunks should run.

persistent_auto_chunk_size(*hpx*::*chrono*::*steady_duration* **const** &*time_cs*, *std*::uint64_t *num_iters_for_timing* = 0)
Construct an persistent_auto_chunk_size executor parameters object

Parameters
- `time_cs`: The execution time for each chunk.

persistent_auto_chunk_size(*hpx*::*chrono*::*steady_duration* **const** &*time_cs*, *hpx*::*chrono*::*steady_duration* **const** &*rel_time*, *std*::uint64_t *num_iters_for_timing* = 0)
Construct an persistent_auto_chunk_size executor parameters object

Parameters
- `rel_time`: [in] The time duration to use as the minimum to decide how many loop iterations should be combined.
- `time_cs`: The execution time for each chunk.

hpx::*bulk_sync_execute_t* **bulk_sync_execute**

hpx::*bulk_async_execute_t* **bulk_async_execute**

hpx::*bulk_then_execute_t* **bulk_then_execute**

struct async_execute_t : **public** *hpx*::*functional*::detail::tag_fallback<*async_execute_t*>
#include <*execution.hpp*> Customization point for asynchronous execution agent creation.

This asynchronously creates a single function invocation f() using the associated executor.

Note Executors have to implement only `async_execute()`. All other functions will be emulated by this or other customization points in terms of this single basic primitive. However, some executors will naturally specialize all operations for maximum efficiency.

Note This is valid for one way executors (calls make_ready_future(exec.sync_execute(f, ts...) if it exists) and for two way executors (calls exec.async_execute(f, ts...) if it exists).

Return f(ts...)'s result through a future

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*async_execute_t*, *Executor &&exec*, *F &&f*, *Ts&&... ts*)

struct bulk_async_execute_t : **public** *hpx*::*functional*::detail::tag_fallback<*bulk_async_execute_t*>
#include <*execution.hpp*> Bulk form of asynchronous execution agent creation.

This asynchronously creates a group of function invocations f(i) whose ordering is given by the execution_category associated with the executor.

Note This is deliberately different from the bulk_async_execute customization points specified in P0443.The bulk_async_execute customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

Here *i* takes on all values in the index space implied by shape. All exceptions thrown by invocations of f(i) are reported in a manner consistent with parallel algorithm execution through the returned future.

Return The return type of *executor_type::bulk_async_execute* if defined by *executor_type*. Otherwise a vector of futures holding the returned values of each invocation of *f*.

Note This calls exec.bulk_async_execute(f, shape, ts...) if it exists; otherwise it executes async_execute(f, shape, ts...) as often as needed.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `shape`: [in] The shape objects which defines the iteration boundaries for the arguments to be passed to *f*.

- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename **Shape**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*bulk_async_execute_t*, *Executor* &&*exec*, *F* &&*f*, *Shape* **const** &*shape*, *Ts*&&... *ts*)

template<typename **Executor**, typename **F**, typename **Shape**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*bulk_async_execute_t*, *Executor* &&*exec*, *F* &&*f*, *Shape* **const** &*shape*, *Ts*&&... *ts*)

struct bulk_sync_execute_t : **public** *hpx*::*functional*::detail::tag_fallback<*bulk_sync_execute_t*>
#include <*execution.hpp*> Bulk form of synchronous execution agent creation.

This synchronously creates a group of function invocations f(i) whose ordering is given by the execution_category associated with the executor. The function synchronizes the execution of all scheduled functions with the caller.

Note This is deliberately different from the bulk_sync_execute customization points specified in P0443.The bulk_sync_execute customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

Here *i* takes on all values in the index space implied by shape. All exceptions thrown by invocations of f(i) are reported in a manner consistent with parallel algorithm execution through the returned future.

Return The return type of *executor_type::bulk_sync_execute* if defined by *executor_type*. Otherwise a vector holding the returned values of each invocation of *f* except when *f* returns void, which case void is returned.

Note This calls exec.bulk_sync_execute(f, shape, ts...) if it exists; otherwise it executes sync_execute(f, shape, ts...) as often as needed.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `shape`: [in] The shape objects which defines the iteration boundaries for the arguments to be passed to *f*.
- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename **Shape**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*bulk_sync_execute_t*, *Executor* &&*exec*, *F* &&*f*, *Shape* **const** &*shape*, *Ts*&&... *ts*)

template<typename **Executor**, typename **F**, typename **Shape**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*bulk_sync_execute_t*, *Executor* &&*exec*, *F* &&*f*, *Shape* **const** &*shape*, *Ts*&&... *ts*)

struct bulk_then_execute_t : **public** *hpx*::*functional*::detail::tag_fallback<*bulk_then_execute_t*>
#include <*execution.hpp*> Bulk form of execution agent creation depending on a given future.

This creates a group of function invocations f(i) whose ordering is given by the execution_category associated with the executor.

Note This is deliberately different from the then_sync_execute customization points specified in P0443.The bulk_then_execute customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

Here *i* takes on all values in the index space implied by shape. All exceptions thrown by invocations of f(i) are reported in a manner consistent with parallel algorithm execution through the returned future.

Return The return type of *executor_type::bulk_then_execute* if defined by *executor_type*. Otherwise a vector holding the returned values of each invocation of *f*.

Note This calls exec.bulk_then_execute(f, shape, pred, ts...) if it exists; otherwise it executes sync_execute(f, shape, pred.share(), ts...) (if this executor is also an OneWayExecutor), or async_execute(f, shape, pred.share(), ts...) (if this executor is also a TwoWayExecutor) - as often as needed.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `shape`: [in] The shape objects which defines the iteration boundaries for the arguments to be passed to *f*.
- `predecessor`: [in] The future object the execution of the given function depends on.
- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename **Shape**, typename **Future**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*bulk_then_execute_t*, *Executor &&exec*, *F &&f*, *Shape* **const** *&shape*, *Future &&predecessor*, *Ts&&... ts*)

template<typename **Executor**, typename **F**, typename **Shape**, typename **Future**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*bulk_then_execute_t*, *Executor &&exec*, *F &&f*, *Shape* **const** *&shape*, *Future &&predecessor*, *Ts&&... ts*)

struct post_t : **public** *hpx*::*functional*::detail::tag_fallback<*post_t*>
#include <*execution.hpp*> Customization point for asynchronous fire & forget execution agent creation.

This asynchronously (fire & forget) creates a single function invocation f() using the associated executor.

Note This is valid for two way executors (calls exec.post(f, ts...), if available, otherwise it calls exec.async_execute(f, ts...) while discarding the returned future), and for non-blocking two way executors (calls exec.post(f, ts...) if it exists).

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*post_t*, *Executor &&exec*, *F &&f*, *Ts&&... ts*)

struct sync_execute_t : **public** *hpx*::*functional*::detail::tag_fallback<*sync_execute_t*>
#include <execution.hpp> Customization point for synchronous execution agent creation.

This synchronously creates a single function invocation f() using the associated executor. The execution of the supplied function synchronizes with the caller

Return f(ts...)'s result

Note This is valid for one way executors only, it will call exec.sync_execute(f, ts...) if it exists.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*sync_execute_t*, *Executor &&exec*, *F &&f*, *Ts&&... ts*)

struct then_execute_t : **public** *hpx*::*functional*::detail::tag_fallback<*then_execute_t*>
#include <execution.hpp> Customization point for execution agent creation depending on a given future.

This creates a single function invocation f() using the associated executor after the given future object has become ready.

Return f(ts...)'s result through a future

Note This is valid for two way executors (calls exec.then_execute(f, predecessor, ts...) if it exists) and for one way executors (calls predecessor.then(bind(f, ts...))).

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `f`: [in] The function which will be scheduled using the given executor.
- `predecessor`: [in] The future object the execution of the given function depends on.
- `ts`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename **Future**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*then_execute_t*, *Executor &&exec*, *F &&f*, *Future &&predecessor*, *Ts&&... ts*)

namespace execution

struct parallel_execution_tag

#include <execution.hpp> Function invocations executed by a group of parallel execution agents execute in unordered fashion. Any such invocations executing in the same thread are indeterminately sequenced with respect to each other.

Note parallel_execution_tag is weaker than sequenced_execution_tag.

struct sequenced_execution_tag

#include <execution.hpp> Function invocations executed by a group of sequential execution agents execute in sequential order.

struct unsequenced_execution_tag

#include <execution.hpp> Function invocations executed by a group of vector execution agents are permitted to execute in unordered fashion when executed in different threads, and un-sequenced with respect to one another when executed in the same thread.

Note unsequenced_execution_tag is weaker than parallel_execution_tag.

namespace hpx

namespace execution

namespace experimental

Functions

template<typename **O**>
void **start** (*O &&o*)

start is a customization point object. The expression `hpx::execution::experimental::start(r)` is equivalent to:

- `r.start()`, if that expression is valid. If the function selected does not signal the receiver `r`'s done channel, the program is ill-formed (no diagnostic required).
- Otherwise, ` start(r), if that expression is valid, with overload resolution performed in a context that include the declaration `void start();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

Variables

hpx::*execution*::*experimental*::start_t **start**

template<typename **O**>
constexpr bool **is_operation_state_v** = *meta*::value<*is_operation_state*<*O*>>

template<typename **O**>
struct is_operation_state

#include <*operation_state.hpp*> An `operation_state` is an object representing the asynchronous operation that has been returned from calling `hpx::execution::experimental::connect` with a `sender` and a `receiver`. The only operation on an `operation_state` is:

- `hpx::execution::experimental::start`

`hpx::execution::experimental::start` can be called exactly once. Once it has been invoked, the caller needs to ensure that the receiver's completion signaling operations strongly happen before the destructor of the state is called. The call to

`hpx::execution::experimental::start` needs to happen strongly before the completion signaling operations.

namespace hpx

namespace execution

namespace experimental

Functions

template<typename **R**, typename ...**As**>
void **set_value**(*R &&r*, *As&&... as*)

set_value is a customization point object. The expression `hpx::execution::set_value(r, as...)` is equivalent to:

- `r.set_value(as...)`, if that expression is valid. If the function selected does not send the value(s) `as...` to the Receiver `r`'s value channel, the program is ill-formed (no diagnostic required).
- Otherwise, ` set_value(r, as...), if that expression is valid, with overload resolution performed in a context that include the declaration `void set_value();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

template<typename **R**>
void **set_stopped**(*R &&r*)

set_stopped is a customization point object. The expression `hpx::execution::set_stopped(r)` is equivalent to:

- `r.set_stopped()`, if that expression is valid. If the function selected does not signal the Receiver `r`'s done channel, the program is ill-formed (no diagnostic required).
- Otherwise, ` set_stopped(r), if that expression is valid, with overload resolution performed in a context that include the declaration `void set_stopped();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

template<typename **R**, typename **E**>
void **set_error**(*R &&r*, *E &&e*)

set_error is a customization point object. The expression `hpx::execution::set_error(r, e)` is equivalent to:

- `r.set_stopped(e)`, if that expression is valid. If the function selected does not send the error `e` the Receiver `r`'s error channel, the program is ill-formed (no diagnostic required).
- Otherwise, ` set_error(r, e), if that expression is valid, with overload resolution performed in a context that include the declaration `void set_error();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

Variables

hpx::*execution*::*experimental*::set_value_t **set_value**

hpx::*execution*::*experimental*::set_error_t **set_error**

template<typename **T**, typename ...**As**>
constexpr bool **is_nothrow_receiver_of_v** = is_nothrow_receiver_of<*T*, *As*...>::value

template<typename **T**, typename **E**>
struct is_receiver

#include <receiver.hpp> Receiving values from asynchronous computations is handled by the `Receiver` concept. A `Receiver` needs to be able to receive an error or be marked as being canceled. As such, the Receiver concept is defined by having the following two customization points defined, which form the completion-signal operations:

- `hpx::execution::experimental::set_stopped`
- `hpx::execution::experimental::set_error`

Those two functions denote the completion-signal operations. The Receiver contract is as follows:

- None of a Receiver's completion-signal operation shall be invoked before `hpx::execution::experimental::start` has been called on the operation state object that was returned by connecting a Receiver to a sender `hpx::execution::experimental::connect`.
- Once `hpx::execution::start` has been called on the operation state object, exactly one of the Receiver's completion-signal operation shall complete without an exception before the Receiver is destroyed

Once one of the Receiver's completion-signal operation has been completed without throwing an exception, the Receiver contract has been satisfied. In other words: The asynchronous operation has been completed.

See *hpx::execution::experimental::is_receiver_of*

template<typename **T**, typename ...**As**>
struct is_receiver_of

#include <receiver.hpp> The `receiver_of` concept is a refinement of the `Receiver` concept by requiring one additional completion-signal operation:

- `hpx::execution::set_value`

This completion-signal operation adds the following to the Receiver's contract:

- If `hpx::execution::set_value` exits with an exception, it is still valid to call `hpx::execution::set_error` or `hpx::execution::set_stopped`

See hpx::execution::traits::is_receiver

namespace hpx

namespace execution_base

struct resource_base

#include <resource_base.hpp> TODO: implement, this is currently just a dummy.

Public Functions

virtual ~resource_base()

namespace hpx

namespace execution

namespace experimental

Typedefs

template<typename **S**, typename **R**>
using connect_result_t = *hpx*::*util*::*invoke_result_t*<*connect_t*, *S*, *R*>

Functions

template<typename **S**, typename **R**>
void **connect**(*S &&s*, *R &&r*)

connect is a customization point object. For some subexpression `s` and `r`, let `S` be the type such that `decltype((s))` is `S` and let `R` be the type such that `decltype((r))` is `R`. The result of the expression `hpx::execution::experimental::connect(s, r)` is then equivalent to:

- `s.connect(r)`, if that expression is valid and returns a type satisfying the `operation_state(`
  See hpx::execution::experimental::traits::is_operation_state) and if `S` satisfies the `sender` concept.
- `s.connect(r)`, if that expression is valid and returns a type satisfying the `operation_state(`
  See hpx::execution::experimental::traits::is_operation_state) and if `S` satisfies the `sender` concept. Overload resolution is performed in a context that include the declaration `void connect();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

Variables

hpx::*execution*::*experimental*::*connect_t* **connect**

hpx::*execution*::*experimental*::schedule_t **schedule**

template<typename **Scheduler**>
constexpr bool **is_scheduler_v** = is_scheduler<*Scheduler*>::value

struct connect_t : **public** *hpx*::*functional*::*tag*<*connect_t*>

#include <*sender.hpp*> The name schedule denotes a customization point object. For some subexpression s, let S be decltype((s)). The expression schedule(s) is expression-equivalent to:

```
* s.schedule(), if that expression is valid and its type models
  sender.
* Otherwise, schedule(s), if that expression is valid and its type
```

(continues on next page)

(continued from previous page)

```
  models sender with overload resolution performed in a context that
  includes the declaration

      void schedule();

  and that does not include a declaration of schedule.

* Otherwise, schedule(s) is ill-formed.
```

The customization is implemented in terms of `hpx::functional::tag_invoke`.

using current_executor = *parallel*::*execution*::*thread_pool_executor*

namespace this_thread

Functions

parallel::*execution*::*current_executor* **get_executor**(*error_code* &*ec* = *throws*)

Returns a reference to the executor which was used to create the current thread.

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

namespace threads

Functions

parallel::*execution*::*current_executor* **get_executor**(thread_id_type **const** *&id*, *error_code &ec = throws*)

Returns a reference to the executor which was used to create the given thread.

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

namespace hpx

namespace execution

Variables

constexpr *sequenced_policy* **seq** = { }

Default sequential execution policy object.

constexpr *parallel_policy* **par** = { }

Default parallel execution policy object.

constexpr *parallel_unsequenced_policy* **par_unseq** = { }

Default vector execution policy object.

constexpr *unsequenced_policy* **unseq** = { }

Default vector execution policy object.

struct parallel_policy

#include <execution_policy.hpp> The class *parallel_policy* is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

Public Types

using executor_type = *parallel_executor*

The type of the executor associated with this execution policy.

using executor_parameters_type = *parallel*::*execution*::*extract_executor_parameters*<*executor_type*>::type

The type of the associated executor parameters object which is associated with this execution policy

using execution_category = *parallel_execution_tag*

The category of the execution agents created by this execution policy.

Public Functions

constexpr *parallel_task_policy* **operator()** (task_policy_tag) **const**
Create a new *parallel_policy* referencing a chunk size.

Return The new *parallel_policy*
Parameters
- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

constexpr decltype(auto) **operator()** (non_task_policy_tag) **const**
Create a new *parallel_policy* from itself

Return The new *parallel_policy*
Parameters
- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

template<typename **Executor**>
constexpr decltype(auto) **on** (*Executor* &&*exec*) **const**
Create a new *parallel_policy* referencing an executor and a chunk size.

Return The new *parallel_policy*
Parameters
- `exec`: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with

template<typename ...**Parameters**>
constexpr decltype(auto) **with** (*Parameters*&&... *params*) **const**
Create a new *parallel_policy* from the given execution parameters

Note Requires: is_executor_parameters<Parameters>::value is true
Return The new *parallel_policy*
Template Parameters
- `Parameters`: The type of the executor parameters to associate with this execution policy.

Parameters
- `params`: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

executor_type &**executor** ()
Return the associated executor object.

constexpr *executor_type* **const** &**executor** () **const**
Return the associated executor object.

executor_parameters_type &**parameters** ()
Return the associated executor parameters object.

constexpr *executor_parameters_type* **const** &**parameters** () **const**
Return the associated executor parameters object.

The type of the rebound execution policy.

template<typename **Executor**, typename **Parameters**>
struct parallel_policy_shim

#include <execution_policy.hpp> The class *parallel_policy_shim* is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

Public Types

template<>
using executor_type = *std*::decay_t<Executor>

The type of the executor associated with this execution policy.

template<>
using executor_parameters_type = *std*::decay_t<Parameters>

The type of the associated executor parameters object which is associated with this execution policy

template<>
using execution_category = **typename** *hpx*::*traits*::executor_execution_category<*executor_type*>::type

The category of the execution agents created by this execution policy.

Public Functions

constexpr parallel_task_policy_shim<Executor, Parameters> **operator()**(task_policy_tag) **const**

Create a new *parallel_policy* referencing a chunk size.

Return The new *parallel_policy*

Parameters

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

constexpr decltype(auto) **operator()**(non_task_policy_tag) **const**

Create a new *parallel_policy* from itself

Return The new *parallel_policy*

Parameters

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

template<typename **Executor_**>
constexpr decltype(auto) **on**(*Executor_ &&exec*) **const**

Create a new *parallel_policy* from the given executor

Note Requires: is_executor<Executor>::value is true

Return The new *parallel_policy*

Template Parameters

- `Executor`: The type of the executor to associate with this execution policy.

Parameters

- `exec`: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with.

template<typename ...**Parameters_**>

namespace hpx

namespace execution

namespace experimental

Functions

std::ostream &**operator<<**(*std*::ostream &*os*, *fork_join_executor*::loop_schedule **const** &*schedule*)

class fork_join_executor

#include <fork_join_executor.hpp> An executor with fork-join (blocking) semantics.

The *fork_join_executor* creates on construction a set of worker threads that are kept alive for the duration of the executor. Copying the executor has reference semantics, i.e. copies of a *fork_join_executor* hold a reference to the worker threads of the original instance. Scheduling work through the executor concurrently from different threads is undefined behaviour.

The executor keeps a set of worker threads alive for the lifetime of the executor, meaning other work will not be executed while the executor is busy or waiting for work. The executor has a customizable delay after which it will yield to other work. Since starting and resuming the worker threads is a slow operation the executor should be reused whenever possible for multiple adjacent parallel algorithms or invocations of bulk_(a)sync_execute.

Public Types

enum loop_schedule

Type of loop schedule for use with the *fork_join_executor*. loop_schedule::static_ implies no work-stealing; loop_schedule::dynamic allows stealing when a worker has finished its local work.

Values:

static_

dynamic

Public Functions

fork_join_executor(*threads*::*thread_priority priority* = *threads*::*thread_priority*::high, *threads*::*thread_stacksize stacksize* = *threads*::*thread_stacksize*::small_, *loop_schedule schedule* = *loop_schedule*::static_, *std*::chrono::nanoseconds *yield_delay* = *std*::chrono::milliseconds(1))

Construct a *fork_join_executor*.

Parameters

- `priority`: The priority of the worker threads.
- `stacksize`: The stacksize of the worker threads. Must not be nostack.
- `schedule`: The loop schedule of the parallel regions.
- `yield_delay`: The time after which the executor yields to other work if it hasn't received any new work for bulk execution.

namespace execution

Typedefs

using parallel_executor = parallel_policy_executor<*hpx*::*launch*>

template<typename **Policy**>
struct parallel_policy_executor

#include <parallel_executor.hpp> A *parallel_executor* creates groups of parallel execution agents which execute in threads implicitly created by the executor. This executor prefers continuing with the creating thread first before executing newly created threads.

This executor conforms to the concepts of a TwoWayExecutor, and a BulkTwoWayExecutor

Public Types

template<>
using execution_category = *parallel_execution_tag*

Associate the parallel_execution_tag executor tag type as a default with this executor.

template<>
using executor_parameters_type = *static_chunk_size*

Associate the static_chunk_size executor parameters type as a default with this executor.

Public Functions

constexpr parallel_policy_executor(*threads*::*thread_priority priority*, *threads*::*thread_stacksize stacksize* = *threads*::*thread_stacksize*::default_, *threads*::*thread_schedule_hint schedulehint* = {}, Policy *l* = *parallel*::*execution*::detail::get_default_policy<Policy>::call(), *std*::size_t *hierarchical_threshold* = hierarchical_threshold_default_)

Create a new parallel executor.

constexpr parallel_policy_executor(*threads*::*thread_stacksize stacksize*, *threads*::*thread_schedule_hint schedulehint* = {}, Policy *l* = *parallel*::*execution*::detail::get_default_policy<Policy>::call())

filesystem

See *Public API* for a list of names and headers that are part of the public *HPX* API.

This file provides a compatibility layer using Boost.Filesystem for the C++17 filesystem library. It is *not* intended to be a complete compatibility layer. It only contains functions required by the HPX codebase. It also provides some functions only available in Boost.Filesystem when using C++17 filesystem.

Invokes the given callable object f with the content of the argument pack vs

Return The result of the callable object when it's called with the given argument types.
Note This function is similar to `std::invoke` (C++17)
Parameters

- `f`: Requires to be a callable object. If f is a member function pointer, the first argument in the pack will be treated as the callee (this object).
- `vs`: An arbitrary pack of arguments

Exceptions

- `std::exception`: like objects thrown by call to object f with the argument types vs.

template<typename **R**, typename **F**, typename ...**Ts**>
constexpr *R* **invoke_r**(*F &&f*, *Ts&&... vs*)

Template Parameters

- `R`: The result type of the function when it's called with the content of the given argument types vs.

namespace hpx

namespace util

Functions

template<typename **F**, typename **Tuple**>
constexpr detail::invoke_fused_result<*F*, *Tuple*>::type **invoke_fused**(*F &&f*, *Tuple &&t*)

Invokes the given callable object f with the content of the sequenced type t (tuples, pairs)

Return The result of the callable object when it's called with the content of the given sequenced type.

Note This function is similar to `std::apply` (C++17)

Parameters

- `f`: Must be a callable object. If f is a member function pointer, the first argument in the sequenced type will be treated as the callee (this object).
- `t`: A type whose contents are accessible through a call to hpx::get.

Exceptions

- `std::exception`: like objects thrown by call to object f with the arguments contained in the sequenceable type t.

template<typename **R**, typename **F**, typename **Tuple**>
constexpr *R* **invoke_fused_r**(*F &&f*, *Tuple &&t*)

Template Parameters

- R: The result type of the function when it's called with the content of the given sequenced type.

class jenkins_hash
#include <jenkins_hash.hpp> The *jenkins_hash* class encapsulates a hash calculation function published by Bob Jenkins here: http://burtleburtle.net/bob/hash

Public Types

enum seedenum
The seedenum is used as a dummy parameter to distinguish the different constructors

Values:

seed = 1

typedef *std*::uint32_t **size_type**
this is the type representing the result of this hash

Public Functions

jenkins_hash()
constructors and destructor

jenkins_hash(*size_type size*)

jenkins_hash(*size_type seedval*, *seedenum*)

~jenkins_hash()

size_type **operator()**(*std*::string **const** &*key*) **const**
calculate the hash value for the given key

size_type **operator()**(char **const** **key*) **const**

bool **reset**(*size_type size*)
re-seed the hash generator

void **set_seed**(*size_type seedval*)
initialize the hash generator to a specific seed

void **swap**(*jenkins_hash &rhs*)
support for std::swap

Protected Functions

size_type **hash**(**const** char **k*, *std*::size_t *length*) **const**

Private Members

size_type **seed_**

io_service

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace util

class io_service_pool

#include <*io_service_pool.hpp*> A pool of io_service objects.

Public Functions

HPX_NON_COPYABLE(*io_service_pool*)

io_service_pool(*std*::size_t *pool_size* = 2, *threads*::*policies*::*callback_notifier* **const** *&notifier* = *threads*::*policies*::*callback_notifier*(), char **const** **pool_name* = "", char **const** **name_postfix* = "")

Construct the io_service pool.

Parameters

- `pool_size`: [in] The number of threads to run to serve incoming requests
- `start_thread`: [in]

io_service_pool(*threads*::*policies*::*callback_notifier* **const** *&notifier*, char **const** **pool_name* = "", char **const** **name_postfix* = "")

Construct the io_service pool.

Parameters

- `start_thread`: [in]

~io_service_pool()

bool **run**(bool *join_threads* = true, *barrier* **startup* = nullptr)

Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete

bool **run**(*std*::size_t *num_threads*, bool *join_threads* = true, *barrier* **startup* = nullptr)

Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete

void **stop**()
Stop all io_service objects in the pool.

void **join**()
Join all io_service threads in the pool.

void **clear**()
Clear all internal data structures.

void **wait**()
Wait for all work to be done.

bool **stopped**()

asio::io_context &**get_io_service**(int *index* = -1)
Get an io_service to use.

std::thread &**get_os_thread_handle**(*std*::size_t *thread_num*)
access underlying thread handle

std::size_t **size**() **const**
Get number of threads associated with this I/O service.

void **thread_run**(*std*::size_t *index*, *barrier* **startup* = nullptr)
Activate the thread *index* for this thread pool.

char **const** ***get_name**() **const**
Return name of this pool.

void **init**(*std*::size_t *pool_size*)

Protected Functions

bool **run_locked**(*std*::size_t *num_threads*, bool *join_threads*, *barrier* **startup*)

void **stop_locked**()

void **join_locked**()

void **clear_locked**()

void **wait_locked**()

Private Types

using io_service_ptr = *std*::unique_ptr<asio::io_context>

using work_type = asio::io_context::work

Private Functions

work_type **initialize_work** (asio::io_context &*io_service*)

Private Members

std::mutex **mtx_**

std::vector<*io_service_ptr*> **io_services_**
The pool of io_services.

std::vector<*std*::thread> **threads_**

std::vector<*work_type*> **work_**
The work that keeps the io_services running.

std::size_t **next_io_service_**
The next io_service to use for a connection.

bool **stopped_**
set to true if stopped

std::size_t **pool_size_**
initial number of OS threads to execute in this pool

threads::*policies*::*callback_notifier* **const** &**notifier_**
call this for each thread start/stop

char **const** ***pool_name_**

char **const** ***pool_name_postfix_**

bool **waiting_**
Set to true if waiting for work to finish.

std::unique_ptr<*barrier*> **wait_barrier_**

std::unique_ptr<*barrier*> **continue_barrier_**

logging

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace util

namespace logging

Enums

enum level

Handling levels - classes that can hold and/or deal with levels.

- filters and level holders

By default we have these levels:

```
- debug (smallest level),
- info,
- warning ,
- error ,
- fatal (highest level)
```

Depending on which level is enabled for your application, some messages will reach the log: those messages having at least that level. For instance, if info level is enabled, all logged messages will reach the log. If warning level is enabled, all messages are logged, but the warnings. If debug level is enabled, messages that have levels debug, error, fatal will be logged.

Values:

disable_all = static_cast<unsigned int>(-1)

enable_all = 0

debug = 1000

info = 2000

warning = 3000

error = 4000

fatal = 5000

always = 6000

Functions

void **format_value**(*std*::ostream &*os*, *boost*::string_ref *spec*, *level value*)

Include this file when you're using the logging lib, but don't necessarily want to use formatters and destinations. If you want to use formatters and destinations, then you can include this one instead:

```
#include <hpx/logging/format.hpp>
```

namespace hpx

namespace util

namespace logging

namespace destination

Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are : *the console*, *a file*, a socket, etc.

struct manipulator

#include <manipulator.hpp> What to use as base class, for your destination classes.

Subclassed by *hpx::util::logging::destination::cerr*, *hpx::util::logging::destination::cout*, *hpx::util::logging::destination::dbg_window*, *hpx::util::logging::destination::file*, *hpx::util::logging::destination::stream*

Public Functions

virtual void **operator()**(*message* **const**&) = 0

virtual void **configure**(*std*::string **const**&)

Override this if you want to allow configuration through scripting.

That is, this allows configuration of your manipulator at run-time.

virtual ~manipulator()

Protected Functions

manipulator()

namespace formatter

Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are : prepend the time, prepend high-precision time, prepend the index of the message, etc.

struct manipulator

#include <manipulator.hpp> What to use as base class, for your formatter classes.

Subclassed by *hpx::util::logging::formatter::high_precision_time*, *hpx::util::logging::formatter::idx*, *hpx::util::logging::formatter::thread_id*

Public Functions

virtual void **operator()**(*std*::ostream&) **const** = 0

virtual void **configure**(*std*::string **const**&)

Override this if you want to allow configuration through scripting.

That is, this allows configuration of your manipulator at run-time.

virtual ~manipulator()

Protected Functions

manipulator()

Friends

void **format_value**(*std*::ostream &*os*, *boost*::string_ref, manipulator **const** &*value*)

namespace hpx

namespace util

namespace logging

class message

#include <message.hpp> Optimizes the formatting for prepending and/or appending strings to the original message.

It keeps all the modified message in one string. Useful if some formatter needs to access the whole string at once.

reserve() - the size that is reserved for prepending (similar to string::reserve function)

Note : as strings are prepended, reserve() shrinks.

Public Functions

message()

message(*std*::stringstream *msg*)
Parameters
- msg: - the message that is originally cached

message(*message* &&*other*)

template<typename **T**>
message &**operator<<**(*T* &&*v*)

template<typename ...**Args**>
message &**format**(*boost*::string_ref *format_str*, *Args* **const**&... *args*)

std::string **const** &**full_string**() **const**
returns the full string

bool **empty**() **const**

Private Members

std::stringstream **m_str**

bool **m_full_msg_computed**

std::string **m_full_msg**

Friends

std::ostream &**operator<<**(*std*::ostream &*os*, message **const** &*value*)

namespace hpx

namespace util

namespace logging

namespace destination
Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are : *the console*, *a file*, a socket, etc.

struct cerr : **public** *hpx*::*util*::*logging*::*destination*::*manipulator*
#include <*destinations.hpp*> Writes the string to cerr.

Public Functions

~cerr()

Public Static Functions

static *std*::unique_ptr<*cerr*> **make**()

Protected Functions

cerr()

struct cout : **public** *hpx*::*util*::*logging*::*destination*::*manipulator*
#include <*destinations.hpp*> Writes the string to console.

Public Functions

~cout()

Public Static Functions

static *std*::unique_ptr<*cout*> **make**()

Protected Functions

cout()

struct dbg_window : **public** *hpx*::*util*::*logging*::*destination*::*manipulator*
#include <*destinations.hpp*> Writes the string to output debug window.

For non-Windows systems, this is the console.

Public Functions

~dbg_window()

Public Static Functions

static *std*::unique_ptr<*dbg_window*> **make**()

Protected Functions

dbg_window()

struct file : **public** *hpx*::*util*::*logging*::*destination*::*manipulator*
#include <*destinations.hpp*> Writes the string to a file.

Public Functions

~file()

Public Static Functions

static *std*::unique_ptr<*file*> **make**(*std*::string **const** &*file_name*, *file_settings set* = { })
constructs the file destination

Parameters
- `file_name`: name of the file
- `set`: [optional] file settings - see *file_settings* class, and dealing_with_flags

Protected Functions

file(*std*::string **const** &*file_name*, *file_settings set*)

Protected Attributes

std::string **name**

file_settings **settings**

struct file_settings
#include <*destinations.hpp*> settings for when constructing a file class. To see how it's used, see dealing_with_flags.

Public Functions

file_settings()

Public Members

bool **flush_each_time** : 1
if true (default), flushes after each write

bool **initial_overwrite** : 1

bool **do_append** : 1

std::ios_base::openmode **extra_flags**
just in case you have some extra flags to pass, when opening the file

struct stream : **public** *hpx*::*util*::*logging*::*destination*::*manipulator*
#include <*destinations.hpp*> writes to stream.

Note : The stream must outlive this object! Or, *clear()* the stream, before the stream is deleted.

Public Functions

~stream()

void **set_stream**(*std*::ostream **stream_ptr*)
resets the stream. Further output will be written to this stream

void **clear**()
clears the stream. Further output will be ignored

Public Static Functions

static *std*::unique_ptr<*stream*> **make**(*std*::ostream **stream_ptr*)

Protected Functions

stream(*std*::ostream **stream_ptr*)

Protected Attributes

std::ostream ***ptr**

namespace hpx

namespace util

namespace logging

namespace formatter
Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are : prepend the time, prepend high-precision time, prepend the index of the message, etc.

struct high_precision_time : **public** *hpx*::*util*::*logging*::*formatter*::*manipulator*
#include <*formatters.hpp*> Prefixes the message with a high-precision time (. You pass the format string at construction.

```
#include <hpx/logging/format/formatter/high_precision_time.hpp>
```

Internally, it uses hpx::util::date_time::microsec_time_clock. So, our precision matches this class.

The format can contain escape sequences: $dd - day, 2 digits $MM - month, 2 digits $yy - year, 2 digits $yyyy - year, 4 digits $hh - hour, 2 digits $mm - minute, 2 digits $ss - second, 2 digits $mili - milliseconds $micro - microseconds (if the high precision clock allows; otherwise, it pads zeros) $nano - nanoseconds (if the high precision clock allows; otherwise, it pads zeros)

Example:

```
high_precision_time("$mm:$ss:$micro");
```

Parameters

- `convert`: [optional] In case there needs to be a conversion between std::(w)string and the string that holds your logged message. See convert_format.

Public Functions

~high_precision_time()

Public Static Functions

static *std*::unique_ptr<*high_precision_time*> **make** (*std*::string **const** &*format*)

Protected Functions

high_precision_time (*std*::string **const** &*format*)

struct idx : **public** *hpx*::*util*::*logging*::*formatter*::*manipulator*

#include <*formatters.hpp*> prefixes each message with an index.

Example:

```
L_ << "my message";
L_ << "my 2nd message";
```

This will output something similar to:

```
[1] my message
[2] my 2nd message
```

Public Functions

~idx()

Public Static Functions

static *std*::unique_ptr<*idx*> **make**()

Protected Functions

idx()

struct thread_id : **public** *hpx*::*util*::*logging*::*formatter*::*manipulator*

#include <*formatters.hpp*> Writes the *thread_id* to the log.

Parameters

- `convert`: [optional] In case there needs to be a conversion between std::(w)string and the string that holds your logged message. See convert_format.

Public Functions

~thread_id()

Public Static Functions

static *std*::unique_ptr<*thread_id*> **make**()

Protected Functions

thread_id()

namespace hpx

namespace util

namespace logging

namespace writer

struct named_write

#include <*named_write.hpp*> Composed of a named formatter and a named destinations. Thus, you can specify the formatting and destinations as strings.

```
#include <hpx/logging/format/named_write.hpp>
```

Contains a very easy interface for using formatters and destinations:
• at construction, specify 2 params: the formatter string and the destinations string
Setting the formatters and destinations to write to is extremely simple:

```
// Set the formatters (first param) and destinatins (second step) in␣
↪one step
g_l()->writer().write("%time%($hh:$mm.$ss.$mili) [%idx%] |\n",
"cout file(out.txt) debug");

// set the formatter(s)
g_l()->writer().format("%time%($hh:$mm.$ss.$mili) [%idx%] |\n");

// set the destination(s)
g_l()->writer().destination("cout file(out.txt) debug");
```

Public Functions

named_write()

void **format**(*std*::string **const** &*format_str*)
sets the format string: what should be before, and what after the original message, separated by "|"

Example: "[%idx%] |\n" - this writes "[%idx%] " before the message, and "\n" after the message

If "|" is not present, the whole message is prepended to the message

void **destination**(*std*::string **const** &*destination_str*)
sets the destinations string - where should logged messages be outputted

void **write**(*std*::string **const** &*format_str*, *std*::string **const** &*destination_str*)
Specifies the formats and destinations in one step.

void **operator()**(*message* **const** &*msg*) **const**

template<typename **Formatter**>
void **set_formatter**(*std*::string **const** &*name*, *Formatter fmt*)
Replaces a formatter from the named formatter.

You can use this, for instance, when you want to share a formatter between multiple named writers.

template<typename **Formatter**, typename ...**Args**>
void **set_formatter**(*std*::string **const** &*name*, *Args*&&... *args*)

template<typename **Destination**>
void **set_destination**(*std*::string **const** &*name*, *Destination dest*)
Replaces a destination from the named destination.

You can use this, for instance, when you want to share a destination between multiple named writers.

template<typename **Destination**, typename ...**Args**>
void **set_destination**(*std*::string **const** &*name*, *Args*&&... *args*)

Private Functions

void **configure_formatter**(*std*::string **const** &*format*)

pack_traversal

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace util

Functions

template<typename Mapper, typename... T><unspecified> hpx::util::map_pack(Mapper &&

Maps the pack with the given mapper.

This function tries to visit all plain elements which may be wrapped in:

- homogeneous containers (`std::vector`, `std::list`)
- heterogeneous containers (`hpx::tuple`, `std::pair`, `std::array`) and re-assembles the pack with the result of the mapper. Mapping from one type to a different one is supported.

Elements that aren't accepted by the mapper are routed through and preserved through the hierarchy.

```
// Maps all integers to floats
map_pack([](int value) {
    return float(value);
},
1, hpx::make_tuple(2, std::vector<int>{3, 4}), 5);
```

Return The mapped element or in case the pack contains multiple elements, the pack is wrapped into a `hpx::tuple`.

Exceptions

- `std::exception`: like objects which are thrown by an invocation to the mapper.

Parameters

- `mapper`: A callable object, which accept an arbitrary type and maps it to another type or the same one.
- `pack`: An arbitrary variadic pack which may contain any type.

namespace hpx

namespace util

Functions

template<typename **Visitor**, typename ...**T**>
auto **traverse_pack_async**(*Visitor &&visitor*, *T&&... pack*)

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
struct my_async_visitor
{
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }
```

(continues on next page)

(continued from previous page)

```
    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.
Return A hpx::intrusive_ptr that references an instance of the given visitor object.
Parameters

- `visitor`: A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should must have a virtual destructor!
- `pack`: The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.

template<typename **Allocator**, typename **Visitor**, typename ...**T**>
auto **traverse_pack_async_allocator**(*Allocator* **const** *&alloc*, *Visitor* *&&visitor*, *T&&... pack*)

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
struct my_async_visitor
{
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }

    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.
Return A hpx::intrusive_ptr that references an instance of the given visitor object.
Parameters

- `visitor`: A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should must have a virtual destructor!
- `pack`: The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.
- `alloc`: Allocator instance to use to create the traversal frame.

namespace hpx

Functions

template<typename ...**Args**>
auto **unwrap** (*Args&&... args*)

A helper function for retrieving the actual result of any hpx::future like type which is wrapped in an arbitrary way.

Unwraps the given pack of arguments, so that any hpx::future object is replaced by its future result type in the argument pack:

- `hpx::future<int>` -> `int`
- `hpx::future<std::vector<float>>` -> `std::vector<float>`
- `std::vector<future<float>>` -> `std::vector<float>`

The function is capable of unwrapping hpx::future like objects that are wrapped inside any container or tuple like type, see hpx::util::map_pack() for a detailed description about which surrounding types are supported. Non hpx::future like types are permitted as arguments and passed through.

```
// Single arguments
int i1 = hpx:unwrap(hpx::make_ready_future(0));

// Multiple arguments
hpx::tuple<int, int> i2 =
    hpx:unwrap(hpx::make_ready_future(1),
               hpx::make_ready_future(2));
```

Note This function unwraps the given arguments until the first traversed nested hpx::future which corresponds to an unwrapping depth of one. See hpx::unwrap_n() for a function which unwraps the given arguments to a particular depth or hpx::unwrap_all() that unwraps all future like objects recursively which are contained in the arguments.

Return Depending on the count of arguments this function returns a hpx::tuple containing the unwrapped arguments if multiple arguments are given. In case the function is called with a single argument, the argument is unwrapped and returned.

Parameters

- `args`: the arguments that are unwrapped which may contain any arbitrary future or non future type.

Exceptions

- `std::exception`: like objects in case any of the given wrapped hpx::future objects were resolved through an exception. See hpx::future::get() for details.

template<*std*::size_t **Depth**, typename ...**Args**>
auto **unwrap_n** (*Args&&... args*)

An alterntive version of hpx::unwrap(), which unwraps the given arguments to a certain depth of hpx::future like objects.

See unwrap for a detailed description.

Template Parameters

- `Depth`: The count of hpx::future like objects which are unwrapped maximally.

template<typename ...**Args**>
auto **unwrap_all**(*Args&&... args*)

An alterntive version of hpx::unwrap(), which unwraps the given arguments recursively so that all contained hpx::future like objects are replaced by their actual value.

See hpx::unwrap() for a detailed description.

template<typename **T**>
auto **unwrapping**(*T &&callable*)

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap() function and then passes the result to the given callable object.

```
auto callable = hpx::unwrapping([](int left, int right) {
    return left + right;
});

int i1 = callable(hpx::make_ready_future(1),
                  hpx::make_ready_future(2));
```

See hpx::unwrap() for a detailed description.

Parameters

- `callable`: the callable object which which is called with the result of the corresponding unwrap function.

template<*std*::size_t **Depth**, typename **T**>
auto **unwrapping_n**(*T &&callable*)

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap_n() function and then passes the result to the given callable object.

See hpx::unwrapping() for a detailed description.

template<typename **T**>
auto **unwrapping_all**(*T &&callable*)

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap_all() function and then passes the result to the given callable object.

See hpx::unwrapping() for a detailed description.

namespace functional

struct unwrap

#include <unwrap.hpp> A helper function object for functionally invoking `hpx::unwrap`. For more information please refer to its documentation.

struct unwrap_all

preprocessor

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_PP_CAT(*A*, *B*)

Concatenates the tokens `A` and `B` into a single token. Evaluates to `AB`

Parameters

- `A`: First token
- `B`: Second token

Defines

HPX_PP_EXPAND(*X*)

The HPX_PP_EXPAND macro performs a double macro-expansion on its argument. This macro can be used to produce a delayed preprocessor expansion.

Parameters

- `X`: Token to be expanded twice

Example:

```
#define MACRO(a, b, c) (a)(b)(c)
#define ARGS() (1, 2, 3)

HPX_PP_EXPAND(MACRO ARGS()) // expands to (1)(2)(3)
```

Defines

HPX_PP_IDENTITY(...)

Defines

HPX_PP_NARGS(...)

Expands to the number of arguments passed in

Example Usage:

```
HPX_PP_NARGS(hpx, pp, nargs)
HPX_PP_NARGS(hpx, pp)
HPX_PP_NARGS(hpx)
```

Parameters

- `...`: The variadic number of arguments

Expands to:

```
3
2
1
```

Defines

HPX_PP_STRINGIZE(*X*)

The *HPX_PP_STRINGIZE* macro stringizes its argument after it has been expanded.

The passed argument `X` will expand to `"X"`. Note that the stringizing operator (#) prevents arguments from expanding. This macro circumvents this shortcoming.

Parameters

- `X`: The text to be converted to a string literal

Defines

HPX_PP_STRIP_PARENS(*X*)

For any symbol `X`, this macro returns the same symbol from which potential outer parens have been removed. If no outer parens are found, this macros evaluates to `X` itself without error.

The original implementation of this macro is from Steven Watanbe as shown in http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976

```
HPX_PP_STRIP_PARENS(no_parens)
HPX_PP_STRIP_PARENS((with_parens))
```

Example Usage:

Parameters

- `X`: Symbol to strip parens from

This produces the following output

```
no_parens
with_parens
```

program_options

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace program_options

namespace command_line_style

Enums

enum style_t

Various possible styles of options.

There are "long" options, which start with "–" and "short", which start with either "-" or "/". Both kinds can be allowed or disallowed, see allow_long and allow_short. The allowed character for short options is also configurable.

Option's value can be specified in the same token as name ("–foo=bar"), or in the next token.

It's possible to introduce long options by the same character as short options, see allow_long_disguise.

Finally, guessing (specifying only prefix of option) and case insensitive processing are supported.

Values:

allow_long = 1
Allow "–long_name" style.

allow_short = *allow_long* << 1
Allow "-<single character" style.

allow_dash_for_short = *allow_short* << 1
Allow "-" in short options.

allow_slash_for_short = *allow_dash_for_short* << 1
Allow "/" in short options.

long_allow_adjacent = *allow_slash_for_short* << 1
Allow option parameter in the same token for long option, like in

```
--foo=10
```

long_allow_next = *long_allow_adjacent* << 1
Allow option parameter in the next token for long options.

short_allow_adjacent = *long_allow_next* << 1
Allow option parameter in the same token for short options.

short_allow_next = *short_allow_adjacent* << 1
Allow option parameter in the next token for short options.

allow_sticky = *short_allow_next* << 1
Allow to merge several short options together, so that "-s -k" become "-sk". All of the options but last should accept no parameter. For example, if "-s" accept a parameter, then "k" will be taken as parameter, not another short option. Dos-style short options cannot be sticky.

allow_guessing = *allow_sticky* << 1
Allow abbreviated spellings for long options, if they unambiguously identify long option. No long option name should be prefix of other long option name if guessing is in effect.

long_case_insensitive = *allow_guessing* << 1
Ignore the difference in case for long options.

short_case_insensitive = *long_case_insensitive* << 1
Ignore the difference in case for short options.

case_insensitive = (*long_case_insensitive* | *short_case_insensitive*)
Ignore the difference in case for all options.

allow_long_disguise = *short_case_insensitive* << 1
Allow long options with single option starting character, e.g `-foo=10`

unix_style = (*allow_short* | *short_allow_adjacent* | *short_allow_next* | *allow_long* | *long_allow_adjacent* | *long*
The more-or-less traditional unix style.

default_style = *unix_style*
The default style.

namespace hpx

namespace program_options

template<class **Derived**, class **ValueType**>
class eof_iterator : **public** *util*::iterator_facade<*Derived*, *ValueType* **const**, *std*::forward_iterator_tag>
#include <eof_iterator.hpp> The '*eof_iterator*' class is useful for constructing forward iterators in cases where iterator extract data from some source and it's easy to detect 'eof' – i.e. the situation where there's no data. One apparent example is reading lines from a file.

Implementing such iterators using 'iterator_facade' directly would require to create class with three core operation, a couple of constructors. When using '*eof_iterator*', the derived class should define only one method to get new value, plus a couple of constructors.

The basic idea is that iterator has 'eof' bit. Two iterators are equal only if both have their 'eof' bits set. The 'get' method either obtains the new value or sets the 'eof' bit.

Specifically, derived class should define:

1. A default constructor, which creates iterator with 'eof' bit set. The constructor body should call 'found_eof' method defined here.
2. Some other constructor. It should initialize some 'data pointer' used in iterator operation and then call 'get'.
3. The 'get' method. It should operate this way:
   - look at some 'data pointer' to see if new element is available; if not, it should call 'found_eof'.
   - extract new element and store it at location returned by the 'value' method.
   - advance the data pointer.

Essentially, the 'get' method has the functionality of both 'increment' and 'dereference'. It's very good for the cases where data extraction implicitly moves data pointer, like for stream operation.

Public Functions

eof_iterator()

Protected Functions

ValueType &**value**()
Returns the reference which should be used by derived class to store the next value.

void **found_eof**()
Should be called by derived class to indicate that it can't produce next element.

namespace program_options

Typedefs

using option = basic_option<char>

using woption = basic_option<wchar_t>

template<class **Char**>
class basic_option

#include <option.hpp> Option found in input source. Contains a key and a value. The key, in turn, can be a string (name of an option), or an integer (position in input source) – in case no name is specified. The latter is only possible for command line. The template parameter specifies the type of char used for storing the option's value.

Public Functions

basic_option()

basic_option(**const** *std*::string &*xstring_key*, **const** *std*::vector<*std*::string> &*xvalue*)

Public Members

std::string **string_key**
String key of this option. Intentionally independent of the template parameter.

int **position_key**
Position key of this option. All options without an explicit name are sequentially numbered starting from 0. If an option has explicit name, 'position_key' is equal to -1. It is possible that both position_key and string_key is specified, in case name is implicitly added.

std::vector<*std*::basic_string<Char>> **value**
Option's value

std::vector<*std*::basic_string<Char>> **original_tokens**
The original unchanged tokens this option was created from.

bool **unregistered**
True if option was not recognized. In that case, 'string_key' and 'value' are results of purely syntactic parsing of source. The original tokens can be recovered from the "original_tokens" member.

bool **case_insensitive**
True if string_key has to be handled case insensitive.

namespace hpx

namespace program_options

class duplicate_option_error : **public** *hpx*::*program_options*::*error*
#include <*options_description.hpp*> Class thrown when duplicate option description is found.

Public Functions

duplicate_option_error(**const** *std*::string &*xwhat*)

class option_description
#include <*options_description.hpp*> Describes one possible command line/config file option. There are two kinds of properties of an option. First describe it syntactically and are used only to validate input. Second affect interpretation of the option, for example default value for it or function that should be called when the value is finally known. Routines which perform parsing never use second kind of properties – they are side effect free.
See *options_description*

Public Types

enum match_result

Values:

no_match

full_match

approximate_match

Public Functions

option_description()

option_description(**const** char **name*, **const** *value_semantic **s*)

Initializes the object with the passed data.

Note: it would be nice to make the second parameter auto_ptr, to explicitly pass ownership. Unfortunately, it's often needed to create objects of types derived from '*value_semantic*': *options_description* d; d.add_options()("a", parameter<int>("n")->default_value(1)); Here, the static type returned by 'parameter' should be derived from *value_semantic*.

Alas, derived->base conversion for auto_ptr does not really work, see http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2000/n1232.pdf http://www.open-std.org/jtc1/sc22/wg21/docs/cwg_defects.html#84

So, we have to use plain old pointers. Besides, users are not expected to use the constructor directly.

The 'name' parameter is interpreted by the following rules:
- if there's no "," character in 'name', it specifies long name
- otherwise, the part before "," specifies long name and the part after – short name.

option_description(**const** char **name*, **const** *value_semantic **s*, **const** char **description*)

Initializes the class with the passed data.

virtual ~option_description()

match_result **match**(**const** *std*::string &*option*, bool *approx*, bool *long_ignore_case*, bool *short_ignore_case*) **const**

Given 'option', specified in the input source, returns 'true' if 'option' specifies *this.

const *std*::string &**key**(**const** *std*::string &*option*) **const**

Returns the key that should identify the option, in particular in the *variables_map* class. The 'option' parameter is the option spelling from the input source. If option name contains '*', returns 'option'. If long name was specified, it's the long name, otherwise it's a short name with pre-pended '-'.

std::string **canonical_display_name**(int *canonical_option_style* = 0) **const**

Returns the canonical name for the option description to enable the user to recognized a matching option. 1) For short options ('-', '/'), returns the short name prefixed. 2) For long options (' / '-') returns the first long name prefixed 3) All other cases, returns the first long name (if present) or the short name, un-prefixed.

const *std*::string &**long_name**() **const**

const *std*::pair<**const** *std*::string*, *std*::size_t> **long_names**() **const**

const *std*::string &**description**() **const**
Explanation of this option.

std::shared_ptr<**const** *value_semantic*> **semantic**() **const**
Semantic of option's value.

std::string **format_name**() **const**
Returns the option name, formatted suitably for usage message.

std::string **format_parameter**() **const**
Returns the parameter name and properties, formatted suitably for usage message.

Private Functions

option_description &**set_names**(**const** char **name*)

Private Members

std::string **m_short_name**
a one-character "switch" name - with its prefix, so that this is either empty or has length 2 (e.g. "-c"

std::vector<*std*::string> **m_long_names**
one or more names by which this option may be specified on a command-line or in a config file, which are not a single-letter switch. The names here are *without* any prefix.

std::string **m_description**

std::shared_ptr<**const** *value_semantic*> **m_value_semantic**

class options_description
#include <options_description.hpp> A set of option descriptions. This provides convenient interface for adding new option (the add_options) method, and facilities to search for options by name.

See here for option adding interface discussion.
See *option_description*

Public Functions

options_description(unsigned *line_length* = *m_default_line_length*, unsigned *min_description_length* = *m_default_line_length* / 2)
Creates the instance.

options_description(**const** *std*::string &*caption*, unsigned *line_length* = *m_default_line_length*, unsigned *min_description_length* = *m_default_line_length* / 2)
Creates the instance. The 'caption' parameter gives the name of this '*options_description*' instance. Primarily useful for output. The 'description_length' specifies the number of columns that should be reserved for the description text; if the option text encroaches into this, then the description will start on the next line.

void **add**(*std*::shared_ptr<*option_description*> *desc*)
Adds new variable description. Throws duplicate_variable_error if either short or long name matches that of already present one.

options_description &**add**(**const** *options_description* &*desc*)
Adds a group of option description. This has the same effect as adding all option_descriptions in 'desc' individually, except that output operator will show a separate group. Returns *this.

std::size_t **get_option_column_width**() **const**
Find the maximum width of the option column, including options in groups.

options_description_easy_init **add_options**()
Returns an object of implementation-defined type suitable for adding options to *options_description*. The returned object will have overloaded operator() with parameter type matching '*option_description*' constructors. Calling the operator will create new *option_description* instance and add it.

const *option_description* &**find**(**const** *std*::string &*name*, bool *approx*, bool *long_ignore_case* = false, bool *short_ignore_case* = false) **const**

const *option_description* ***find_nothrow**(**const** *std*::string &*name*, bool *approx*, bool *long_ignore_case* = false, bool *short_ignore_case* = false) **const**

const *std*::vector<*std*::shared_ptr<*option_description*>> &**options**() **const**

void **print**(*std*::ostream &*os*, *std*::size_t *width* = 0) **const**
Outputs 'desc' to the specified stream, calling 'f' to output each *option_description* element.

Public Static Attributes

const unsigned **m_default_line_length**

Private Types

namespace hpx

namespace program_options

Typedefs

using parsed_options = basic_parsed_options<char>

using wparsed_options = *basic_parsed_options*<wchar_t>

using ext_parser = *std*::function<*std*::pair<*std*::string, *std*::string> (**const** *std*::string&) >
Augments *basic_parsed_options<wchar_t>* with conversion from 'parsed_options'

using command_line_parser = basic_command_line_parser<char>

using wcommand_line_parser = basic_command_line_parser<wchar_t>

Enums

enum collect_unrecognized_mode
Controls if the 'collect_unregistered' function should include positional options, or not.

Values:

include_positional

exclude_positional

Functions

template<class **Char**>
basic_parsed_options<*Char*> **parse_command_line**(int *argc*, **const** *Char* ***const** *argv*[], **const** *options_description*&, int *style* = 0, *std*::function<*std*::pair<*std*::string, *std*::string>) **const** *std*::string&
> *ext* = *ext_parser*()Creates instance of 'command_line_parser', passes parameters to it, and returns the result of calling the 'run' method.

template<class **Char**>
basic_parsed_options<*Char*> **parse_config_file**(*std*::basic_istream<*Char*>&, **const** *options_description*&, bool *allow_unregistered* = false)
Parse a config file.

Read from given stream.

template<class **Char** = char>
basic_parsed_options<*Char*> **parse_config_file**(**const** char **filename*, **const** *options_description*&, bool *allow_unregistered* = false)
Parse a config file.

Read from file with the given name. The character type is passed to the file stream.

template<class **Char**>
std::vector<*std*::basic_string<*Char*>> **collect_unrecognized**(**const** *std*::vector<basic_option<*Char*>> &*options*, **enum** *collect_unrecognized_mode* *mode*)
Collects the original tokens for all named options with 'unregistered' flag set. If 'mode' is 'include_positional' also collects all positional options. Returns the vector of original tokens for all collected options.

parsed_options **parse_environment**(**const** *options_description*&, **const** *std*::function<*std*::string) *std*::string
> &*name_mapper*Parse environment.

For each environment variable, the 'name_mapper' function is called to obtain the option name. If it returns empty string, the variable is ignored.

This is done since naming of environment variables is typically different from the naming of command line options.

parsed_options **parse_environment**(**const** *options_description*&, **const** *std*::string &*prefix*)
Parse environment.

Takes all environment variables which start with 'prefix'. The option name is obtained from variable name by removing the prefix and converting the remaining string into lower case.

parsed_options **parse_environment**(**const** *options_description*&, **const** char **prefix*)
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. This function exists to resolve ambiguity between the two above functions when second argument is of 'char*' type. There's implicit conversion to both std::function and string.

std::vector<*std*::string> **split_unix**(**const** *std*::string &*cmdline*, **const** *std*::string &*separator* = " \t", **const** *std*::string &*quote* = "'\"", **const** *std*::string &*escape* = "\\")

Splits a given string to a collection of single strings which can be passed to command_line_parser. The second parameter is used to specify a collection of possible separator chars used for splitting. The separator is defaulted to space " ". Splitting is done in a unix style way, with respect to quotes '"' and escape characters '\'

std::vector<std::wstring> hpx::program_options::split_unix(const std::wstring & cmd

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class **Char**>
class basic_command_line_parser : **private** cmdline

#include <parsers.hpp> Command line parser.

The class allows one to specify all the information needed for parsing and to parse the command line. It is primarily needed to emulate named function parameters – a regular function with 5 parameters will be hard to use and creating overloads with a smaller number of parameters will be confusing.

For the most common case, the function parse_command_line is a better alternative.

There are two typedefs – command_line_parser and wcommand_line_parser, for charT == char and charT == wchar_t cases.

Public Functions

basic_command_line_parser(**const** *std*::vector<*std*::basic_string<Char>> &*args*)

Creates a command line parser for the specified arguments list. The 'args' parameter should not include program name.

basic_command_line_parser(int *argc*, **const** Char ***const** *argv*[])

Creates a command line parser for the specified arguments list. The parameters should be the same as passed to 'main'.

basic_command_line_parser &**options**(**const** *options_description* &*desc*)

Sets options descriptions to use.

basic_command_line_parser &**positional**(**const** *positional_options_description* &*desc*)

Sets positional options description to use.

basic_command_line_parser &**style**(int)

Sets the command line style.

basic_command_line_parser &**extra_parser**(*ext_parser*)

Sets the extra parsers.

basic_parsed_options<Char> **run**()

Parses the options and returns the result of parsing. Throws on error.

basic_command_line_parser &**allow_unregistered**()

Specifies that unregistered options are allowed and should be passed though. For each command like token that looks like an option but does not contain a recognized name, an instance of basic_option<charT> will be added to result, with 'unrecognized' field set to 'true'. It's possible to collect all unrecognized options with the 'collect_unrecognized' function.

basic_command_line_parser &**extra_style_parser**(style_parser *s*)

Private Members

const *options_description* ***m_desc**

template<class **Char**>
class basic_parsed_options

#include <parsers.hpp> Results of parsing an input source. The primary use of this class is passing information from parsers component to value storage component. This class does not makes much sense itself.

Public Functions

basic_parsed_options(**const** *options_description *xdescription*, int *options_prefix* = 0)

Public Members

std::vector<basic_option<Char>> **options**

Options found in the source.

const *options_description* ***description**

Options description that was used for parsing. Parsers should return pointer to the instance of *option_description* passed to them, and issues of lifetime are up to the caller. Can be NULL.

int **m_options_prefix**

Mainly used for the diagnostic messages in exceptions. The canonical option prefix for the parser which generated these results, depending on the settings for *basic_command_line_parser::style()* or cmdline::style(). In order of precedence of command_line_style enums: allow_long allow_long_disguise allow_dash_for_short allow_slash_for_short

template<>
class basic_parsed_options<wchar_t>

#include <parsers.hpp> Specialization of *basic_parsed_options* which:

- provides convenient conversion from *basic_parsed_options<char>*
- stores the passed char-based options for later use.

Public Functions

basic_parsed_options(**const** *basic_parsed_options*<char> &*po*)

Constructs wrapped options from options in UTF8 encoding.

Public Members

std::vector<basic_option<wchar_t>> **options**

const *options_description* ***description**

basic_parsed_options<char> **utf8_encoded_options**

Stores UTF8 encoded options that were passed to constructor, to avoid reverse conversion in some cases.

int **m_options_prefix**
Mainly used for the diagnostic messages in exceptions. The canonical option prefix for the parser which generated these results, depending on the settings for *basic_command_line_parser::style()* or cmdline::style(). In order of precedence of command_line_style enums: allow_long allow_long_disguise allow_dash_for_short allow_slash_for_short

namespace hpx

namespace program_options

class positional_options_description
#include <positional_options.hpp> Describes positional options.

The class allows to guess option names for positional options, which are specified on the command line and are identified by the position. The class uses the information provided by the user to associate a name with every positional option, or tell that no name is known.

The primary assumption is that only the relative order of the positional options themselves matters, and that any interleaving ordinary options don't affect interpretation of positional options.

The user initializes the class by specifying that first N positional options should be given the name X1, following M options should be given the name X2 and so on.

Public Functions

positional_options_description()

positional_options_description &**add**(**const** char **name*, int *max_count*)
Species that up to 'max_count' next positional options should be given the 'name'. The value of '-1' means 'unlimited'. No calls to 'add' can be made after call with 'max_value' equal to '-1'.

unsigned **max_total_count**() **const**
Returns the maximum number of positional options that can be present. Can return (numeric_limits<unsigned>::max)() to indicate unlimited number.

const *std*::string &**name_for_position**(unsigned *position*) **const**
Returns the name that should be associated with positional options at 'position'. Precondition: position < *max_total_count()*

Private Members

std::vector<*std*::string> **m_names**

std::string **m_trailing**

namespace hpx

namespace program_options

Functions

template<class **T**>
typed_value<*T*> ***value**()
Creates a typed_value<T> instance. This function is the primary method to create *value_semantic* instance for a specific type, which can later be passed to '*option_description*' constructor. The second overload is used when it's additionally desired to store the value of option into program variable.

template<class **T**>
typed_value<*T*> ***value**(*T* **v*)
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class **T**>
typed_value<*T*, wchar_t> ***wvalue**()
Creates a typed_value<T> instance. This function is the primary method to create *value_semantic* instance for a specific type, which can later be passed to '*option_description*' constructor.

template<class **T**>
typed_value<*T*, wchar_t> ***wvalue**(*T* **v*)
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

typed_value<bool> ***bool_switch**()
Works the same way as the 'value<bool>' function, but the created *value_semantic* won't accept any explicit value. So, if the option is present on the command line, the value will be 'true'.

typed_value<bool> ***bool_switch**(bool **v*)
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class **T**, class **Char** = char>
class typed_value : **public** *hpx*::*program_options*::*value_semantic_codecvt_helper*<char>, **public** *hpx*::*progran*
#include <*value_semantic.hpp*> Class which handles value of a specific type.

Public Functions

typed_value(T **store_to*)
Ctor. The 'store_to' parameter tells where to store the value when it's known. The parameter can be NULL.

typed_value ***default_value**(**const** T &*v*)
Specifies default value, which will be used if none is explicitly specified. The type 'T' should provide operator<< for ostream.

typed_value ***default_value**(**const** T &*v*, **const** *std*::string &*textual*)
Specifies default value, which will be used if none is explicitly specified. Unlike the above overload, the type 'T' need not provide operator<< for ostream, but textual representation of default value must be provided by the user.

typed_value ***implicit_value**(**const** T &*v*)
Specifies an implicit value, which will be used if the option is given, but without an adjacent value. Using this implies that an explicit value is optional,

typed_value ***value_name**(**const** *std*::string &*name*)
Specifies the name used to to the value in help message.

typed_value ***implicit_value**(**const** T &*v*, **const** *std*::string &*textual*)
Specifies an implicit value, which will be used if the option is given, but without an adjacent value. Using this implies that an explicit value is optional, but if given, must be strictly adjacent to the option, i.e.: '-ovalue' or 'option=value'. Giving '-o' or 'option' will cause the implicit value to be applied. Unlike the above overload, the type 'T' need not provide operator<< for ostream, but textual representation of default value must be provided by the user.

typed_value ***notifier**(*std*::function<void>) **const** T&
>*f*Specifies a function to be called when the final value is determined.

typed_value ***composing**()
Specifies that the value is composing. See the 'is_composing' method for explanation.

typed_value ***multitoken**()
Specifies that the value can span multiple tokens.

typed_value ***zero_tokens**()
Specifies that no tokens may be provided as the value of this option, which means that only presence of the option is significant. For such option to be useful, either the 'validate' function should be specialized, or the 'implicit_value' method should be also used. In most cases, you can use the 'bool_switch' function instead of using this method.

typed_value ***required**()
Specifies that the value must occur.

std::string **name**() **const**
Returns the name of the option. The name is only meaningful for automatic help message.

bool **is_composing**() **const**
Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

unsigned **min_tokens**() **const**
The minimum number of tokens for this option that should be present on the command line.

unsigned **max_tokens**() **const**
The maximum number of tokens for this option that should be present on the command line.

bool **is_required**() **const**
Returns true if value must be given. Non-optional value

void **xparse**(*hpx*::*any_nonser* &*value_store*, **const** *std*::vector<*std*::basic_string<Char>> &*new_tokens*) **const**
Creates an instance of the 'validator' class and calls its operator() to perform the actual conversion.

virtual bool **apply_default**(*hpx*::*any_nonser* &*value_store*) **const**
If default value was specified via previous call to 'default_value', stores that value into 'value_store'. Returns true if default value was stored.

void **notify**(**const** *hpx*::*any_nonser* &*value_store*) **const**
If an address of variable to store value was specified when creating *this, stores the value there. Otherwise, does nothing.

const *std*::type_info &**value_type**() **const**

class typed_value_base

#include <*value_semantic.hpp*> Base class for all option that have a fixed type, and are willing to announce this type to the outside world. Any 'value_semantics' for which you want to find out the type can be dynamic_cast-ed to *typed_value_base*. If conversion succeeds, the 'type' method can be called.

Subclassed by *hpx::program_options::typed_value< T, Char >*

Public Functions

virtual const *std*::type_info &**value_type** () **const** = 0

virtual ~typed_value_base ()

class untyped_value : **public** *hpx*::*program_options*::*value_semantic_codecvt_helper*<char>

#include <*value_semantic.hpp*> Class which specifies a simple handling of a value: the value will have string type and only one token is allowed.

Public Functions

untyped_value (bool *zero_tokens* = false)

std::string **name** () **const**

Returns the name of the option. The name is only meaningful for automatic help message.

unsigned **min_tokens** () **const**

The minimum number of tokens for this option that should be present on the command line.

unsigned **max_tokens** () **const**

The maximum number of tokens for this option that should be present on the command line.

bool **is_composing** () **const**

Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

bool **is_required**() **const**
Returns true if value must be given. Non-optional value

void **xparse**(*hpx*::*any_nonser* &*value_store*, **const** *std*::vector<*std*::string> &*new_tokens*) **const**
If 'value_store' is already initialized, or new_tokens has more than one elements, throws. Otherwise, assigns the first string from 'new_tokens' to 'value_store', without any modifications.

bool **apply_default**(*hpx*::*any_nonser*&) **const**
Does nothing.

void **notify**(**const** *hpx*::*any_nonser*&) **const**
Does nothing.

Private Members

bool **m_zero_tokens**

class value_semantic
#include <*value_semantic.hpp*> Class which specifies how the option's value is to be parsed and converted into C++ types.

Subclassed by *hpx::program_options::value_semantic_codecvt_helper*< *char* >, *hpx::program_options::value_semantic_codecvt_helper*< *wchar_t* >

Public Functions

virtual *std*::string **name**() **const** = 0
Returns the name of the option. The name is only meaningful for automatic help message.

virtual unsigned **min_tokens**() **const** = 0
The minimum number of tokens for this option that should be present on the command line.

virtual unsigned **max_tokens**() **const** = 0
The maximum number of tokens for this option that should be present on the command line.

virtual bool **is_composing**() **const** = 0
Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

virtual bool **is_required**() **const** = 0
Returns true if value must be given. Non-optional value

virtual void **parse**(*hpx*::*any_nonser* &*value_store*, **const** *std*::vector<*std*::string> &*new_tokens*, bool *utf8*) **const** = 0
Parses a group of tokens that specify a value of option. Stores the result in 'value_store', using whatever representation is desired. May be be called several times if value of the same option is specified more than once.

virtual bool **apply_default**(*hpx*::*any_nonser* &*value_store*) **const** = 0
Called to assign default value to 'value_store'. Returns true if default value is assigned, and false if no default value exists.

virtual void **notify**(**const** *hpx*::*any_nonser* &*value_store*) **const** = 0
Called when final value of an option is determined.

virtual ~value_semantic()

template<class **Char**>
class value_semantic_codecvt_helper
#include <value_semantic.hpp> Helper class which perform necessary character conversions in the 'parse' method and forwards the data further.

template<>
class value_semantic_codecvt_helper<char> : **public** *hpx::program_options::value_semantic*
#include <value_semantic.hpp> Helper conversion class for values that accept ascii strings as input. Overrides the 'parse' method and defines new 'xparse' method taking std::string. Depending on whether input to parse is ascii or UTF8, will pass it to xparse unmodified, or with UTF8->ascii conversion.

Subclassed by *hpx::program_options::typed_value< T, Char >*, *hpx::program_options::untyped_value*

Protected Functions

Parses a group of tokens that specify a value of option. Stores the result in 'value_store', using whatever representation is desired. May be be called several times if value of the same option is specified more than once.

namespace hpx

namespace program_options

Functions

void **store**(**const** basic_parsed_options<char> &*options*, *variables_map* &*m*, bool *utf8* = false)
Stores in 'm' all options that are defined in 'options'. If 'm' already has a non-defaulted value of an option, that value is not changed, even if 'options' specify some value.

void **store**(**const** *basic_parsed_options*<wchar_t> &*options*, *variables_map* &*m*)
Stores in 'm' all options that are defined in 'options'. If 'm' already has a non-defaulted value of an option, that value is not changed, even if 'options' specify some value. This is wide character variant.

void **notify**(*variables_map* &*m*)
Runs all 'notify' function for options in 'm'.

class abstract_variables_map
#include <*variables_map.hpp*> Implements string->string mapping with convenient value casting facilities.

Subclassed by *hpx::program_options::variables_map*

Public Functions

abstract_variables_map()

abstract_variables_map(**const** *abstract_variables_map* **next*)

virtual ~abstract_variables_map()

const *variable_value* &**operator[]**(**const** *std*::string &*name*) **const**
Obtains the value of variable 'name', from *this and possibly from the chain of variable maps.

- if there's no value in *this.
  - if there's next variable map, returns value from it
  - otherwise, returns empty value
- if there's defaulted value
  - if there's next variable map, which has a non-defaulted value, return that
  - otherwise, return value from *this
- if there's a non-defaulted value, returns it.

void **next**(*abstract_variables_map* **next*)
Sets next variable map, which will be used to find variables not found in *this.

Private Functions

virtual const *variable_value* &**get**(**const** *std*::string &*name*) **const** = 0
Returns value of variable 'name' stored in *this, or empty value otherwise.

Private Members

const *abstract_variables_map* ***m_next**

class variable_value

#include <*variables_map.hpp*> Class holding value of option. Contains details about how the value is set and allows to conveniently obtain the value.

Public Functions

variable_value()

variable_value(**const** *hpx*::*any_nonser* &*xv*, bool *xdefaulted*)

template<class **T**>
const *T* &**as**() **const**
If stored value if of type T, returns that value. Otherwise, throws boost::bad_any_cast exception.

template<class **T**>
T &**as**()
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool **empty**() **const**
Returns true if no value is stored.

bool **defaulted**() **const**
Returns true if the value was not explicitly given, but has default value.

hpx::*any_nonser* &**value**() **const**
Returns the contained value.

hpx::*any_nonser* &**value**()
Returns the contained value.

Private Members

hpx::*any_nonser* **v**

bool **m_defaulted**

std::shared_ptr<**const** *value_semantic*> **m_value_semantic**

Friends

friend hpx::program_options::variables_map

void **store**(**const** basic_parsed_options<char> &*options*, variables_map &*m*, bool *utf8*)
Stores in 'm' all options that are defined in 'options'. If 'm' already has a non-defaulted value of an option, that value is not changed, even if 'options' specify some value.

class variables_map : **public** *hpx*::*program_options*::*abstract_variables_map*, **public** *std*::map<*std*::string, *var*

#include <*variables_map.hpp*> Concrete variables map which store variables in real map.

This class is derived from std::map<std::string, variable_value>, so you can use all map operators to examine its content.

Public Functions

variables_map()

variables_map(**const** *abstract_variables_map* **next*)

const *variable_value* &**operator[]**(**const** *std*::string &*name*) **const**

void **clear**()

void **notify**()

Private Functions

const *variable_value* &**get**(**const** *std*::string &*name*) **const**
Implementation of abstract_variables_map::get which does 'find' in *this.

Private Members

std::set<*std*::string> **m_final**
Names of option with 'final' values – which should not be changed by subsequence assignments.

std::map<*std*::string, *std*::string> **m_required**
Names of required options, filled by parser which has access to *options_description*. The map values are the "canonical" names for each corresponding option. This is useful in creating diagnostic messages when the option is absent.

Friends

void **store**(**const** basic_parsed_options<char> &*options*, variables_map &*xm*, bool *utf8*)
Stores in 'm' all options that are defined in 'options'. If 'm' already has a non-defaulted value of an option, that value is not changed, even if 'options' specify some value.

Defines

HPX_PROGRAM_OPTIONS_VERSION
The version of the source interface. The value will be incremented whenever a change is made which might cause compilation errors for existing code.

HPX_PROGRAM_OPTIONS_IMPLICIT_VALUE_NEXT_TOKEN

Enums

enum partitioner_mode

This enumeration describes the modes available when creating a resource partitioner.

Values:

mode_default = 0

Default mode.

mode_allow_oversubscription = 1

Allow processing units to be oversubscribed, i.e. multiple worker threads to share a single processing unit.

mode_allow_dynamic_pools = 2

Allow worker threads to be added and removed from thread pools.

enum scheduling_policy

This enumeration lists the available scheduling policies (or schedulers) when creating thread pools.

Values:

user_defined = -2

unspecified = -1

local = 0

local_priority_fifo = 1

local_priority_lifo = 2

static_ = 3

static_priority = 4

abp_priority_fifo = 5

abp_priority_lifo = 6

shared_priority = 7

Functions

detail::partitioner &**get_partitioner**()
May be used anywhere in code and returns a reference to the single, global resource partitioner.

bool **is_partitioner_valid**()
Returns true if the resource partitioner has been initialized. Returns false otherwise.

runtime_configuration

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_REGISTER_COMMANDLINE_REGISTRY(*RegistryType*, *componentname*)
The macro *HPX_REGISTER_COMMANDLINE_REGISTRY* is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_COMMANDLINE_REGISTRY_DYNAMIC(*RegistryType*, *componentname*)

HPX_REGISTER_COMMANDLINE_OPTIONS()
The macro *HPX_REGISTER_COMMANDLINE_OPTIONS* is used to define the required Hpx.Plugin entry point for the command line option registry. This macro has to be used in not more than one compilation unit of a component module.

HPX_REGISTER_COMMANDLINE_OPTIONS_DYNAMIC()

namespace hpx

namespace components

struct component_commandline_base
#include <component_commandline_base.hpp> The component_commandline_base has to be used as a base class for all component command-line line handling registries.

Public Functions

virtual ~component_commandline_base()

virtual *hpx::program_options::options_description* **add_commandline_options**() = 0
Return any additional command line options valid for this component.

Return The module is expected to fill a options_description object with any additional command line options this component will handle.
Note This function will be executed by the runtime system during system startup.

Defines

HPX_REGISTER_COMPONENT_FACTORY(*componentname*)
This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the component factories.

HPX_REGISTER_COMPONENT_MODULE()
This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

HPX_REGISTER_COMPONENT_MODULE_DYNAMIC()

Defines

HPX_REGISTER_COMPONENT_REGISTRY(*RegistryType*, *componentname*)
This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_COMPONENT_REGISTRY_DYNAMIC(*RegistryType*, *componentname*)

HPX_REGISTER_REGISTRY_MODULE()
This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

HPX_REGISTER_REGISTRY_MODULE_DYNAMIC()

namespace hpx

namespace components

struct component_registry_base
#include <component_registry_base.hpp> The component_registry_base has to be used as a base class for all component registries.

Public Functions

virtual ~component_registry_base()

virtual bool **get_component_info**(*std*::vector<*std*::string> &*fillini*, *std*::string **const** &*filepath*, bool *is_static* = false) = 0

Return the ini-information for all contained components.

Return Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

Parameters

- `fillini`: [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

virtual void **register_component_type**() = 0

Return the unique identifier of the component type this factory is responsible for.

Return Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.

Parameters

- `locality`: [in] The id of the locality this factory is responsible for.
- `agas_client`: [in] The AGAS client to use for component id registration (if needed).

HPX_REGISTER_PLUGIN_BASE_REGISTRY(*PluginType*, *name*)

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_PLUGIN_REGISTRY_MODULE()

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

HPX_REGISTER_PLUGIN_REGISTRY_MODULE_DYNAMIC()

namespace hpx

namespace plugins

struct plugin_registry_base

#include <plugin_registry_base.hpp> The plugin_registry_base has to be used as a base class for all plugin registries.

Public Functions

virtual ~plugin_registry_base()

virtual bool **get_plugin_info**(*std*::vector<*std*::string> *&fillini*) = 0

Return the configuration information for any plugin implemented by this module

Return Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

Parameters

- `fillini`: [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all plugins implemented in this module.

Enums

enum runtime_mode

A HPX runtime can be executed in two different modes: console mode and worker mode.

Values:

invalid = -1

console = 0

The runtime is the console locality.

worker = 1

The runtime is a worker locality.

connect = 2

The runtime is a worker locality connecting late

local = 3

The runtime is fully local.

default_ = 4

The runtime mode will be determined based on the command line arguments

last

Functions

char **const** ***get_runtime_mode_name**(*runtime_mode state*)

Get the readable string representing the name of the given runtime_mode constant.

runtime_mode **get_runtime_mode_from_name**(*std*::string **const** &*mode*)

Returns the internal representation (runtime_mode constant) from the readable string representing the name.

This represents the internal representation from the readable string representing the name.

Parameters

- `mode`: this represents the runtime mode

Defines

HPX_REGISTER_STARTUP_SHUTDOWN_REGISTRY(*RegistryType*, *componentname*)

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_STARTUP_SHUTDOWN_REGISTRY_DYNAMIC(*RegistryType*, *componentname*)

HPX_REGISTER_STARTUP_SHUTDOWN_FUNCTIONS()

This macro is used to define the required Hpx.Plugin entry point for the startup/shutdown registry. This macro has to be used in not more than one compilation unit of a component module.

HPX_REGISTER_STARTUP_SHUTDOWN_FUNCTIONS_DYNAMIC()

namespace hpx

namespace components

struct component_startup_shutdown_base

#include <*component_startup_shutdown_base.hpp*> The component_startup_shutdown_base has to be used as a base class for all component startup/shutdown registries.

Public Functions

virtual ~component_startup_shutdown_base()

virtual bool **get_startup_function**(*startup_function_type* &*startup*, bool &*pre_startup*) = 0

Return any startup function for this component.

Return Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

Parameters

- `startup`: [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

virtual bool **get_shutdown_function**(*shutdown_function_type* &*shutdown*, bool &*pre_shutdown*) = 0

Return any startup function for this component.

Return Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

Parameters

- `shutdown`: [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

namespace hpx

Functions

std::string **get_config_entry**(*std*::string **const** &*key*, *std*::string **const** &*dflt*)
Retrieve the string value of a configuration entry given by `key`.

std::string **get_config_entry**(*std*::string **const** &*key*, *std*::size_t *dflt*)
Retrieve the integer value of a configuration entry given by `key`.

void **set_config_entry**(*std*::string **const** &*key*, *std*::string **const** &*value*)
Set the string value of a configuration entry given by `key`.

void **set_config_entry**(*std*::string **const** &*key*, *std*::size_t *value*)
Set the integer value of a configuration entry given by `key`.

void **set_config_entry_callback**(*std*::string **const** &*key*, *hpx*::function<void) *std*::string **const**&, *std*::string **const**&
> **const** &*callback*Set the string value of a configuration entry given by `key`.

namespace hpx

Functions

std::string **diagnostic_information**(*exception_info* **const** &*xi*)
Extract the diagnostic information embedded in the given exception and return a string holding a formatted message.

The function *hpx::diagnostic_information* can be used to extract all diagnostic information stored in the given exception instance as a formatted string. This simplifies debug output as it composes the diagnostics into one, easy to use function call. This includes the name of the source file and line number, the sequence number of the OS-thread and the HPX-thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

Return The formatted string holding all of the available diagnostic information stored in the given exception instance.

See *hpx::get_error_locality_id()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for all diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if any of the required allocation operations fail)

std::uint32_t **get_error_locality_id**(*hpx*::*exception_info* **const** &*xi*)

Return the locality id where the exception was thrown.

The function *hpx::get_error_locality_id* can be used to extract the diagnostic information element representing the locality id as stored in the given exception instance.

Return The locality id of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return *hpx::naming::invalid_locality_id*.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `nothing`:

std::string **get_error_host_name**(*hpx*::*exception_info* **const** &*xi*)

Return the hostname of the locality where the exception was thrown.

The function *hpx::get_error_host_name* can be used to extract the diagnostic information element representing the host name as stored in the given exception instance.

Return The hostname of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return and empty string.

See *hpx::diagnostic_information()* *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()* *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

std::int64_t **get_error_process_id**(*hpx*::*exception_info* **const** &*xi*)

Return the (operating system) process id of the locality where the exception was thrown.

The function *hpx::get_error_process_id* can be used to extract the diagnostic information element representing the process id as stored in the given exception instance.

Return The process id of the OS-process which threw the exception If the exception instance does not hold this information, the function will return 0.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `nothing`:

std::string **`get_error_env`**(*hpx*::*exception_info* **const** &*xi*)

Return the environment of the OS-process at the point the exception was thrown.

The function *hpx::get_error_env* can be used to extract the diagnostic information element representing the environment of the OS-process collected at the point the exception was thrown.

Return The environment from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

std::string **`get_error_backtrace`**(*hpx*::*exception_info* **const** &*xi*)

Return the stack backtrace from the point the exception was thrown.

The function *hpx::get_error_backtrace* can be used to extract the diagnostic information element representing the stack backtrace collected at the point the exception was thrown.

Return The stack back trace from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

std::size_t **`get_error_os_thread`**(*hpx*::*exception_info* **const** &*xi*)

Return the sequence number of the OS-thread used to execute HPX-threads from which the exception was thrown.

The function *hpx::get_error_os_thread* can be used to extract the diagnostic information element representing the sequence number of the OS-thread as stored in the given exception instance.

Return The sequence number of the OS-thread used to execute the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size(-1).

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `nothing`:

std::size_t **`get_error_thread_id`**(*hpx*::*exception_info* **const** &*xi*)

Return the unique thread id of the HPX-thread from which the exception was thrown.

The function *hpx::get_error_thread_id* can be used to extract the diagnostic information element representing the HPX-thread id as stored in the given exception instance.

Return The unique thread id of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size_t(0).

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()* *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `nothing`:

std::string **get_error_thread_description**(*hpx*::*exception_info* **const** &*xi*)

Return any additionally available thread description of the HPX-thread from which the exception was thrown.

The function *hpx::get_error_thread_description* can be used to extract the diagnostic information element representing the additional thread description as stored in the given exception instance.

Return Any additionally available thread description of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error()*, *hpx::get_error_state()*, *hpx::get_error_what()*, *hpx::get_error_config()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

std::string **get_error_config**(*hpx*::*exception_info* **const** &*xi*)

Return the HPX configuration information point from which the exception was thrown.

The function *hpx::get_error_config* can be used to extract the HPX configuration information element representing the full HPX configuration information as stored in the given exception instance.

Return Any additionally available HPX configuration information the point from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error()*, *hpx::get_error_state()* *hpx::get_error_what()*, *hpx::get_error_thread_description()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

std::string **get_error_state**(*hpx*::*exception_info* **const** &*xi*)

Return the HPX runtime state information at which the exception was thrown.

The function *hpx::get_error_state* can be used to extract the HPX runtime state information element representing the state the runtime system is currently in as stored in the given exception instance.

Return The point runtime state at the point at which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error()*, *hpx::get_error_what()*, *hpx::get_error_thread_description()*

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

namespace hpx

namespace util

Functions

void **may_attach_debugger**(*std*::string **const** &*category*)
Attaches a debugger if `category` is equal to the configuration entry hpx.attach-debugger.

namespace hpx

Functions

std::uint32_t **get_locality_id**(*error_code* &*ec* = *throws*)
Return the number of the locality this function is being called from.

This function returns the id of the current locality.

Note The returned value is zero based and its maximum value is smaller than the overall number of localities the current application is running on (as returned by get_num_localities()).

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

namespace hpx

Functions

std::string **get_locality_name**()

Return the name of the locality this function is called on.

This function returns the name for the locality on which this function is called.

Return This function returns the name for the locality on which the function is called. The name is retrieved from the underlying networking layer and may be different for different parcelports.

See *future<std::string>* get_locality_name(hpx::id_type const& id)

namespace hpx

Functions

std::uint32_t **get_initial_num_localities**()

Return the number of localities which were registered at startup for the running application.

The function *get_initial_num_localities* returns the number of localities which were connected to the console at application startup.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

See *hpx::find_all_localities*, *hpx::get_num_localities*

hpx::future<*std*::uint32_t> **get_num_localities**()

Asynchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* asynchronously returns the number of localities currently connected to the console. The returned future represents the actual result.

Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See *hpx::find_all_localities*, *hpx::get_num_localities*

std::uint32_t **get_num_localities**(*launch*::sync_policy, *error_code* &*ec* = *throws*)

Return the number of localities which are currently registered for the running application.

The function *get_num_localities* returns the number of localities currently connected to the console.

Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

See *hpx::find_all_localities*, *hpx::get_num_localities*

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

namespace hpx

Functions

std::size_t **get_os_thread_count**()
Return the number of OS-threads running in the runtime instance the current HPX-thread is associated with.

std::size_t **get_os_thread_count**(*threads*::executor **const** &*exec*)
Return the number of worker OS- threads used by the given executor to execute HPX threads.

This function returns the number of cores used to execute HPX threads for the given executor. If the function is called while no HPX runtime system is active, it will return zero. If the executor is not valid, this function will fall back to retrieving the number of OS threads used by HPX.

Parameters

- `exec`: [in] The executor to be used.

namespace hpx

Functions

std::string **get_thread_name**()
Return the name of the calling thread.

This function returns the name of the calling thread. This name uniquely identifies the thread in the context of HPX. If the function is called while no HPX runtime system is active, the result will be "<unknown>".

namespace hpx

namespace runtime_local

Enums

enum os_thread_type

Types of kernel threads registered with the runtime.

Values:

unknown = -1

main_thread = 0

kernel thread represents main thread

worker_thread

kernel thread is used to schedule HPX threads

io_thread

kernel thread can be used for IO operations

timer_thread

kernel is used by timer operations

parcel_thread

kernel is used by networking operations

custom_thread

kernel is registered by the application

Functions

std::string **get_os_thread_type_name**(*os_thread_type type*)
Return a human-readable name representing one of the kernel thread types.

struct os_thread_data
#include <*os_thread_type.hpp*> Registration data for kernel threads that is maintained by the runtime internally

Public Members

std::string **label_**
name used for thread registration

std::thread::id **id_**
thread id of corresponding kernel thread

std::uint64_t **native_handle_**
the threads native handle

os_thread_type **type_**
HPX thread type.

Functions

void **set_error_handlers**()

class runtime

Public Types

using notification_policy_type = *threads*::*policies*::*callback_notifier*
Generate a new notification policy instance for the given thread name prefix

using hpx_main_function_type = int()
The *hpx_main_function_type* is the default function type usable as the main HPX thread function.

using hpx_errorsink_function_type = void(*std*::uint32_t, *std*::string **const**&)

Public Functions

virtual *notification_policy_type* **get_notification_policy**(char **const** **prefix*, *runtime_local*::*os_thread_type type*)

state **get_state**() **const**

void **set_state**(*state s*)

runtime(*hpx*::*util*::*runtime_configuration* &*rtcfg*, bool *initialize*)
Construct a new HPX runtime instance.

virtual ~runtime()
The destructor makes sure all HPX runtime services are properly shut down before exiting.

void **on_exit**(*hpx*::function<void)
> **const** &*f*Manage list of functions to call on exit.

void **starting**()
Manage runtime 'stopped' state.

void **stopping**()
Call all registered on_exit functions.

bool **stopped**() **const**
This accessor returns whether the runtime instance has been stopped.

hpx::*util*::*runtime_configuration* &**get_config**()
access configuration information

hpx::*util*::*runtime_configuration* **const** &**get_config**() **const**

std::size_t **get_instance_number**() **const**

util::*thread_mapper* &**get_thread_mapper**()
Return a reference to the internal PAPI thread manager.

threads::*topology* **const** &**get_topology**() **const**

virtual int **run**(*hpx*::function<*hpx_main_function_type*> **const** &*func*)
Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

Note The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

Return This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

Parameters

- `func`: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

virtual int **run**()

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

Return This function will always return 0 (zero).

virtual void **rethrow_exception**()

Rethrow any stored exception (to be called after *stop()*)

virtual int **start**(*hpx*::function<*hpx_main_function_type*> **const** &*func*, bool *blocking* = false)

Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

Parameters

- `func`: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*.
- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function runtime::start will call runtime::wait internally.

virtual int **start**(bool *blocking* = false)

Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

Parameters

- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function runtime::start will call runtime::wait internally .

virtual int **wait**()

Wait for the shutdown action to be executed.

Return This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

virtual void **stop**(bool *blocking* = true)

Initiate termination of the runtime system.

Parameters

- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

virtual int **suspend**()

Suspend the runtime system.

virtual int **resume**()

Resume the runtime system.

virtual int **finalize**(double)

virtual bool **is_networking_enabled**()
Return true if networking is enabled.

virtual *hpx*::*threads*::*threadmanager* &**get_thread_manager**()
Allow access to the thread manager instance used by the HPX runtime.

virtual *std*::string **here**() **const**
Returns a string of the locality endpoints (usable in debug output)

virtual bool **report_error**(*std*::size_t *num_thread*, *std*::exception_ptr **const** &*e*, bool *terminate_all* = true)
Report a non-recoverable error to the runtime system.

Parameters
- `num_thread`: [in] The number of the operating system thread the error has been detected in.
- `e`: [in] This is an instance encapsulating an exception which lead to this function call.

virtual bool **report_error**(*std*::exception_ptr **const** &*e*, bool *terminate_all* = true)
Report a non-recoverable error to the runtime system.

Note This function will retrieve the number of the current shepherd thread and forward to the report_error function above.
Parameters
- `e`: [in] This is an instance encapsulating an exception which lead to this function call.

virtual void **add_pre_startup_function**(*startup_function_type f*)
Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with *add_startup_function*.

Note The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.
Parameters
- `f`: The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

virtual void **add_startup_function**(*startup_function_type f*)
Add a function to be executed inside a HPX thread before hpx_main

Parameters
- `f`: The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

virtual void **add_pre_shutdown_function**(*shutdown_function_type f*)
Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

Note The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.
Parameters

- `f`: The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

virtual void **add_shutdown_function**(*shutdown_function_type f*)

Add a function to be executed inside a HPX thread during hpx::finalize

Parameters

- `f`: The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

virtual *hpx*::*util*::*io_service_pool* ***get_thread_pool**(char **const** **name*)

Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are "main_pool", "io_pool", "parcel_pool", and "timer_pool". For any other argument value the function will return zero.

virtual bool **register_thread**(char **const** **name*, *std*::size_t *num* = 0, bool *service_thread* = true, *error_code* &*ec* = *throws*)

Register an external OS-thread with HPX.

This function should be called from any OS-thread which is external to HPX (not created by HPX), but which needs to access HPX functionality, such as setting a value on a promise or similar.

'main', 'io', 'timer', 'parcel', 'worker'

Note The function will compose a thread name of the form '<name>-thread#<num>' which is used to register the thread. It is the user's responsibility to ensure that each (composed) thread name is unique. HPX internally uses the following names for the threads it creates, do not reuse those:

Parameters

- `name`: [in] The name to use for thread registration.
- `num`: [in] The sequence number to use for thread registration. The default for this parameter is zero.
- `service_thread`: [in] The thread should be registered as a service thread. The default for this parameter is 'true'. Any service threads will be pinned to cores not currently used by any of the HPX worker threads.

Note This function should be called for each thread exactly once. It will fail if it is called more than once.

Return This function will return whether the requested operation succeeded or not.

virtual bool **unregister_thread**()

Unregister an external OS-thread with HPX.

This function will unregister any external OS-thread from HPX.

Note This function should be called for each thread exactly once. It will fail if it is called more than once. It will fail as well if the thread has not been registered before (see *register_thread*).

Return This function will return whether the requested operation succeeded or not.

virtual *runtime_local*::*os_thread_data* **get_os_thread_data**(*std*::string **const** &*label*) **const**

Access data for a given OS thread that was previously registered by *register_thread*.

virtual bool **enumerate_os_threads**(*hpx*::function<bool> *runtime_local*::*os_thread_data* **const**& > **const** &*f* **const**Enumerate all OS threads that have registered with the runtime.

notification_policy_type::on_startstop_type **on_start_func**() **const**

namespace threads

Functions

char **const** ***get_stack_size_name**(*std*::ptrdiff_t *size*)
Returns the stack size name.

Get the readable string representing the given stack size constant.

Parameters
- `size`: this represents the stack size

std::ptrdiff_t **get_default_stack_size**()
Returns the default stack size.

Get the default stack size in bytes.

std::ptrdiff_t **get_stack_size**(*thread_stacksize*)
Returns the stack size corresponding to the given stack size enumeration.

Get the stack size corresponding to the given stack size enumeration.

Parameters
- `size`: this represents the stack size

namespace util

Functions

bool **retrieve_commandline_arguments**(*hpx*::*program_options*::*options_description* **const** &*app_options*, *hpx*::*program_options*::*variables_map* &*vm*)

bool **retrieve_commandline_arguments**(*std*::string **const** &*appname*, *hpx*::*program_options*::*variables_map* &*vm*)

namespace hpx

Functions

bool **register_thread**(*runtime *rt*, char **const** **name*, *error_code &ec = throws*)
Register the current kernel thread with HPX, this should be done once for each external OS-thread intended to invoke HPX functionality. Calling this function more than once will return false.

void **unregister_thread**(*runtime *rt*)
Unregister the thread from HPX, this should be done once in the end before the external thread exists.

runtime_local::*os_thread_data* **get_os_thread_data**(*std*::string **const** *&label*)
Access data for a given OS thread that was previously registered by *register_thread*. This function must be called from a thread that was previously registered with the runtime.

bool **enumerate_os_threads**(*hpx*::function<bool) os_thread_data **const**&
> **const** *&f*Enumerate all OS threads that have registered with the runtime.

std::size_t **get_runtime_instance_number**()
Return the runtime instance number associated with the runtime instance the current thread is running in.

bool **register_on_exit**(*hpx*::function<void)
> **const**&Register a function to be called during system shutdown.

bool **is_starting**()
Test whether the runtime system is currently being started.

This function returns whether the runtime system is currently being started or not, e.g. whether the current state of the runtime system is *hpx::state::startup*

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

bool **tolerate_node_faults**()
Test if HPX runs in fault-tolerant mode.

This function returns whether the runtime system is running in fault-tolerant mode

bool **is_running**()
Test whether the runtime system is currently running.

This function returns whether the runtime system is currently running or not, e.g. whether the current state of the runtime system is *hpx::state::running*

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

bool **is_stopped**()
Test whether the runtime system is currently stopped.

This function returns whether the runtime system is currently stopped or not, e.g. whether the current state of the runtime system is *hpx::hpx::state::stopped*

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

bool **is_stopped_or_shutting_down**()
Test whether the runtime system is currently being shut down.

This function returns whether the runtime system is currently being shut down or not, e.g. whether the current state of the runtime system is *hpx::state::stopped* or *hpx::state::shutdown*

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

std::size_t **get_num_worker_threads**()
Return the number of worker OS- threads used to execute HPX threads.

This function returns the number of OS-threads used to execute HPX threads. If the function is called while no HPX runtime system is active, it will return zero.

std::uint64_t **get_system_uptime**()
Return the system uptime measure on the thread executing this call.

This function returns the system uptime measured in nanoseconds for the thread executing this call. If the function is called while no HPX runtime system is active, it will return zero.

namespace hpx

namespace parallel

namespace execution

Enums

enum service_executor_type

timer_pool_executor()

namespace hpx

Typedefs

typedef *hpx*::move_only_function<void()> **shutdown_function_type**

The type of a function which is registered to be executed as a shutdown or pre-shutdown function.

Functions

void **register_pre_shutdown_function**(*shutdown_function_type f*)

Add a function to be executed by a HPX thread during *hpx::finalize()* but guaranteed before any shutdown function is executed (system-wide)

Any of the functions registered with *register_pre_shutdown_function* are guaranteed to be executed by an HPX thread during the execution of *hpx::finalize()* before any of the registered shutdown functions are executed (see: *hpx::register_shutdown_function()*).

Note If this function is called while the pre-shutdown functions are being executed, or after that point, it will raise a invalid_status exception.

See *hpx::register_shutdown_function()*

Parameters

- `f`: [in] The function to be registered to run by an HPX thread as a pre-shutdown function.

void **register_shutdown_function**(*shutdown_function_type f*)

Add a function to be executed by a HPX thread during *hpx::finalize()* but guaranteed after any pre-shutdown function is executed (system-wide)

Any of the functions registered with *register_shutdown_function* are guaranteed to be executed by an HPX thread during the execution of *hpx::finalize()* after any of the registered pre-shutdown functions are executed (see: *hpx::register_pre_shutdown_function()*).

Note If this function is called while the shutdown functions are being executed, or after that point, it will raise a invalid_status exception.

See *hpx::register_pre_shutdown_function()*

Parameters

- `f`: [in] The function to be registered to run by an HPX thread as a shutdown function.

namespace hpx

Typedefs

typedef *hpx*::move_only_function<void()> **startup_function_type**

The type of a function which is registered to be executed as a startup or pre-startup function.

Functions

void **register_pre_startup_function**(*startup_function_type f*)

Add a function to be executed by a HPX thread before hpx_main but guaranteed before any startup function is executed (system-wide).

Any of the functions registered with *register_pre_startup_function* are guaranteed to be executed by an HPX thread before any of the registered startup functions are executed (see hpx::register_startup_function()).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

Note If this function is called while the pre-startup functions are being executed or after that point, it will raise a invalid_status exception.

Parameters

- `f`: [in] The function to be registered to run by an HPX thread as a pre-startup function.

See hpx::register_startup_function()

void **register_startup_function**(*startup_function_type f*)

Add a function to be executed by a HPX thread before hpx_main but guaranteed after any pre-startup function is executed (system-wide).

Any of the functions registered with *register_startup_function* are guaranteed to be executed by an HPX thread after any of the registered pre-startup functions are executed (see: hpx::register_pre_startup_function()), but before *hpx_main* is being called.

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

Note If this function is called while the startup functions are being executed or after that point, it will raise a invalid_status exception.

Parameters

- `f`: [in] The function to be registered to run by an HPX thread as a startup function.

See hpx::register_pre_startup_function()

namespace hpx

namespace threads

Functions

bool **threadmanager_is**(*state st*)

bool **threadmanager_is_at_least**(*state st*)

namespace hpx

Functions

threads::*policies*::*callback_notifier*::*on_startstop_type* **get_thread_on_start_func**()

Retrieve the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *register_thread_on_start_func*).

Return The currently installed error handler function.

Note This function can be called before the HPX runtime is initialized.

threads::*policies*::*callback_notifier*::*on_startstop_type* **get_thread_on_stop_func**()

Retrieve the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *register_thread_on_stop_func*).

Return The currently installed error handler function.

Note This function can be called before the HPX runtime is initialized.

threads::*policies*::*callback_notifier*::*on_error_type* **get_thread_on_error_func**()

Retrieve the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function

reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *register_thread_on_error_func*).

Return The currently installed error handler function.

Note This function can be called before the HPX runtime is initialized.

threads::*policies*::*callback_notifier*::*on_startstop_type* **register_thread_on_start_func**(*threads*::*policies*::*callback_no*
&&*f*)

Set the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *get_thread_on_start_func*).

Return The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

Note This function can be called before the HPX runtime is initialized.

Parameters

- `f`: The function to install as the new start handler.

threads::*policies*::*callback_notifier*::*on_startstop_type* **register_thread_on_stop_func**(*threads*::*policies*::*callback_not*
&&*f*)

Set the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *get_thread_on_stop_func*).

Return The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

Note This function can be called before the HPX runtime is initialized.

Parameters

- `f`: The function to install as the new stop handler.

threads::*policies*::*callback_notifier*::*on_error_type* **register_thread_on_error_func**(*threads*::*policies*::*callback_notifi*
&&*f*)

Set the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *get_thread_on_error_func*).

Return The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

Note This function can be called before the HPX runtime is initialized.

Parameters

- `f`: The function to install as the new error handler.

namespace resource

Functions

std::size_t **get_num_thread_pools**()
Return the number of thread pools currently managed by the *resource_partitioner*

std::size_t **get_num_threads**()
Return the number of threads in all thread pools currently managed by the *resource_partitioner*

std::size_t **get_num_threads**(*std*::string **const** &*pool_name*)
Return the number of threads in the given thread pool currently managed by the *resource_partitioner*

std::size_t **get_num_threads**(*std*::size_t *pool_index*)
Return the number of threads in the given thread pool currently managed by the *resource_partitioner*

std::size_t **get_pool_index**(*std*::string **const** &*pool_name*)
Return the internal index of the pool given its name.

std::string **const** &**get_pool_name**(*std*::size_t *pool_index*)
Return the name of the pool given its internal index.

threads::*thread_pool_base* &**get_thread_pool**(*std*::string **const** &*pool_name*)
Return the name of the pool given its name.

threads::*thread_pool_base* &**get_thread_pool**(*std*::size_t *pool_index*)
Return the thread pool given its internal index.

bool **pool_exists**(*std*::string **const** &*pool_name*)
Return true if the pool with the given name exists.

bool **pool_exists**(*std*::size_t *pool_index*)
Return true if the pool with the given index exists.

namespace threads

Functions

std::int64_t **get_thread_count**(*thread_schedule_state state* = *thread_schedule_state*::unknown)

The function *get_thread_count* returns the number of currently known threads.

Note If state == unknown this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

Parameters

- `state`: [in] This specifies the thread-state for which the number of threads should be retrieved.

std::int64_t **get_thread_count**(*thread_priority priority*, *thread_schedule_state state* = *thread_schedule_state*::unknown)

The function *get_thread_count* returns the number of currently known threads.

Note If state == unknown this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

Parameters

- `priority`: [in] This specifies the thread-priority for which the number of threads should be retrieved.
- `state`: [in] This specifies the thread-state for which the number of threads should be retrieved.

std::int64_t **get_idle_core_count**()

The function *get_idle_core_count* returns the number of currently idling threads (cores).

mask_type **get_idle_core_mask**()

The function *get_idle_core_mask* returns a bit-mask representing the currently idling threads (cores).

bool **enumerate_threads**(*hpx*::function<bool) thread_id_type > **const** &*f*, *thread_schedule_state state* = *thread_schedule_state*::unknownThe function *enumerate_threads* will invoke the given function *f* for each thread with a matching thread state.

Parameters

- `f`: [in] The function which should be called for each matching thread. Returning 'false' from this function will stop the enumeration process.
- `state`: [in] This specifies the thread-state for which the threads should be enumerated.

template<typename **Mutex** = *std*::mutex, typename **PendingQueuing** = *concurrentqueue_fifo*, typename **Termina**
class shared_priority_queue_scheduler : **public** *scheduler_base*

#include <shared_priority_queue_scheduler.hpp> The *shared_priority_queue_scheduler* maintains a set of high, normal, and low priority queues. For each priority level there is a core/queue ratio which determines how many cores share a single queue. If the high priority core/queue ratio is 4 the first 4 cores will share a single high priority queue, the next 4 will share another one and so on. In addition, the *shared_priority_queue_scheduler* is NUMA-aware and takes NUMA scheduling hints into account when creating and scheduling work.

Warning: PendingQueuing lifo causes lockup on termination

class static_priority_queue_scheduler : **public** *hpx*::*threads*::*policies*::local_priority_queue_schedu

#include <*static_priority_queue_scheduler.hpp*> The *static_priority_queue_scheduler* maintains exactly one queue of work items (threads) per OS thread, where this OS thread pulls its next work from. Additionally it maintains separate queues: several for high priority threads and one for low priority threads. High priority threads are executed by the first N OS threads before any other

work is executed. Low priority threads are executed by the last OS thread whenever no other work is available. This scheduler does not do any work stealing.

Public Types

namespace hpx

namespace experimental

template<typename **ReadWriteT**, typename **ReadT**, typename **Allocator**>
class async_rw_mutex

#include <async_rw_mutex.hpp> Read-write mutex where access is granted to a value through senders.

The wrapped value is accessed through read and readwrite, both of which return senders which call set_value on a connected receiver when the wrapped value is safe to read or write. The senders send the value through a wrapper type which is implicitly convertible to a reference of the wrapped value. Read-only senders send wrappers that are convertible to const references.

A read-write sender gives exclusive access to the wrapped value, while a read-only sender gives shared (with other read-only senders) access to the value.

A void mutex acts as a mutex around some user-managed resource, i.e. the void mutex does not manage any value and the types sent by the senders are not convertible. The sent types are copyable and release access to the protected resource when released.

The order in which senders call set_value is determined by the order in which the senders are retrieved from the mutex. Connecting and starting the senders is thread-safe.

Retrieving senders from the mutex is not thread-safe.

The mutex is movable and non-copyable.

template<typename **OnCompletion** = detail::empty_oncompletion>
class barrier

#include <barrier.hpp> A barrier is a thread coordination mechanism whose lifetime consists of a sequence of barrier phases, where each phase allows at most an expected number of threads to block until the expected number of threads arrive at the barrier. [Note: A barrier is useful for managing repeated tasks that are handled by multiple threads. - end note] Each barrier phase consists of the following steps:

- The expected count is decremented by each call to arrive or arrive_and_drop.
- When the expected count reaches zero, the phase completion step is run. For the specialization with the default value of the CompletionFunction template parameter, the completion step is run as part of the call to arrive or arrive_and_drop that caused the expected count to reach zero. For other specializations, the completion step is run on one of the threads that arrived at the barrier during the phase.
- When the completion step finishes, the expected count is reset to what was specified by the expected argument to the constructor, possibly adjusted by calls to arrive_and_drop, and the next phase starts.

Each phase defines a phase synchronization point. Threads that arrive at the barrier during the phase can block on the phase synchronization point by calling wait, and will remain blocked until the phase completion step is run. The phase completion step that is executed at the end of each phase has the following effects:

- Invokes the completion function, equivalent to completion().
- Unblocks all threads that are blocked on the phase synchronization point.

The end of the completion step strongly happens before the returns from all calls that were unblocked by the completion step. For specializations that do not have the default value of the CompletionFunction template parameter, the behavior is undefined if any of the barrier object's member functions other than wait are called while the completion step is in progress.

Concurrent invocations of the member functions of barrier, other than its destructor, do not introduce data races. The member functions arrive and arrive_and_drop execute atomically.

CompletionFunction shall meet the Cpp17MoveConstructible (Table 28) and Cpp17Destructible (Table 32) requirements. std::is_nothrow_invocable_v<CompletionFunction&> shall be true.

The default value of the CompletionFunction template parameter is an unspecified type, such that, in addition to satisfying the requirements of CompletionFunction, it meets the Cpp17DefaultConstructible requirements (Table 27) and completion() has no effects.

barrier::arrival_token is an unspecified type, such that it meets the Cpp17MoveConstructible (Table 28), Cpp17MoveAssignable (Table 30), and Cpp17Destructible (Table 32) requirements.

Public Types

template<>
using arrival_token = bool

Public Functions

constexpr barrier(*std*::ptrdiff_t *expected*, OnCompletion *completion* = OnCompletion())

Preconditions: expected >= 0 is true and expected <= max() is true.

Effects: Sets both the initial expected count for each barrier phase and the current expected count for the first phase to expected. Initializes completion with std::move(f). Starts the first phase. [Note: If expected is 0 this object can only be destroyed.- end note]

Exceptions

•

arrival_token **arrive**(*std*::ptrdiff_t *update* = 1)

Preconditions: update > 0 is true, and update is less than or equal to the expected count for the current barrier phase.

Effects: Constructs an object of type arrival_token that is associated with the phase synchronization point for the current phase. Then, decrements the expected count by update.

Synchronization: The call to arrive strongly happens before the start of the phase completion step for the current phase.

Return : The constructed arrival_token object.

Exceptions

•

void **wait**(arrival_token &&*old_phase*) **const**

Preconditions: arrival is associated with the phase synchronization point for the current phase or the immediately preceding phase of the same barrier object.

Effects: Blocks at the synchronization point associated with HPX_MOVE(arrival) until the phase completion step of the synchronization point's phase is run. [Note: If arrival is associated with the synchronization point for a previous phase, the call returns immediately. - end note]

Exceptions

•

void **arrive_and_wait**()

Effects: Equivalent to: wait(arrive()).

void **arrive_and_drop**()

Preconditions: The expected count for the current barrier phase is greater than zero.

Effects: Decrements the initial expected count for all subsequent phases by one. Then decrements the expected count for the current phase by one.

Synchronization: The call to arrive_and_drop strongly happens before the start of the phase completion step for the current phase.

Exceptions

•

namespace hpx

class latch

#include <latch.hpp> Latches are a thread coordination mechanism that allow one or more threads to block until an operation is completed. An individual latch is a singleuse object; once the operation has been completed, the latch cannot be reused.

Subclassed by *hpx::lcos::local::latch*

Public Functions

HPX_NON_COPYABLE(*latch*)

latch(*std*::ptrdiff_t *count*)

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.

~latch()

Requires: No threads are blocked at the synchronization point.

Note May be called even if some threads have not yet returned from *wait()* or count_down_and_wait(), provided that counter_ is 0.

Note The destructor might not return until all threads have exited *wait()* or count_down_and_wait().

Note It is the caller's responsibility to ensure that no other thread enters *wait()* after one thread has called the destructor. This may require additional coordination.

void **count_down**(*std*::ptrdiff_t *update*)

Decrements counter_ by n. Does not block.

Requires: counter_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all try_wait calls on this latch that return true .

Exceptions

- `Nothing.`:

bool **try_wait**() **const**

Returns: With very low probability false. Otherwise counter == 0.

void **wait**() **const**

If counter_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter_ reaches 0.

Exceptions

- `Nothing.`:

void **arrive_and_wait**(*std*::ptrdiff_t *update* = 1)

Effects: Equivalent to: count_down(update); *wait()*;

Public Static Functions

static constexpr std::ptrdiff_t() hpx::latch::max()

Returns: The maximum value of counter that the implementation supports.

Protected Types

using mutex_type = *hpx*::*lcos*::*local*::*spinlock*

util::*cache_line_data*<*mutex_type*> **mtx_**

util::*cache_line_data*<*hpx*::*lcos*::*local*::detail::condition_variable> **cond_**

std::atomic<*std*::ptrdiff_t> **counter_**

bool **notified_**

namespace lcos

namespace local

class latch : **public** *hpx*::*latch*

#include <latch.hpp> A latch maintains an internal counter_ that is initialized when the latch is created. Threads may block at a synchronization point waiting for counter_ to be decremented to 0. When counter_ reaches 0, all such blocked threads are released.

Calls to countdown_and_wait() , *count_down()* , *wait()* , *is_ready()*, *count_up()* , and *reset()* behave as atomic operations.

Note A hpx::latch is not an LCO in the sense that it has no global id and it can't be triggered using the action (parcel) mechanism. Use hpx::distributed::latch instead if this is required. It is just a low level synchronization primitive allowing to synchronize a given number of *threads*.

Public Functions

HPX_NON_COPYABLE(*latch*)

latch(*std*::ptrdiff_t *count*)

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.

~latch()

Requires: No threads are blocked at the synchronization point.

Note May be called even if some threads have not yet returned from *wait()* or *count_down_and_wait()*, provided that counter_ is 0.

Note The destructor might not return until all threads have exited *wait()* or *count_down_and_wait()*.

Note It is the caller's responsibility to ensure that no other thread enters *wait()* after one thread has called the destructor. This may require additional coordination.

void **count_down_and_wait**()

Decrements counter_ by 1 . Blocks at the synchronization point until counter_ reaches 0.

Requires: counter_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

Exceptions

- `Nothing.`:

bool **`is_ready`**`()` **`const`**

Returns: counter_ == 0. Does not block.

Exceptions

- `Nothing.`:

void **`abort_all`**`()`

void **`count_up`**`(`*std*::ptrdiff_t *n*`)`

Increments counter_ by n. Does not block.

Requires: n >= 0.

Exceptions

- `Nothing.`:

void **`reset`**`(`*std*::ptrdiff_t *n*`)`

Reset counter_ to n. Does not block.

Requires: n >= 0.

Exceptions

- `Nothing.`:

bool **`reset_if_needed_and_count_up`**`(`*std*::ptrdiff_t *n*, *std*::ptrdiff_t *count*`)`

Effects: Equivalent to: if (*is_ready()*) reset(count); count_up(n); Returns: true if the latch was reset

Typedefs

typedef sliding_semaphore_var **sliding_semaphore**

template<typename **Mutex** = *hpx*::*lcos*::*local*::*spinlock*>
class sliding_semaphore_var

#include <sliding_semaphore.hpp> A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Sliding semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. The difference to a counting semaphore is that a sliding semaphore will not limit the number of threads which are allowed to proceed, but will make sure that the difference between the (arbitrary) number passed to set and wait does not exceed a given threshold.

Public Functions

sliding_semaphore_var(*std*::int64_t *max_difference*, *std*::int64_t *lower_limit* = 0)

Construct a new sliding semaphore.

Parameters

- `max_difference`: [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- `lower_limit`: [in] The initial lower limit.

void **set_max_difference**(*std*::int64_t *max_difference*, *std*::int64_t *lower_limit* = 0)

Set/Change the difference that will cause the semaphore to trigger.

Parameters

- `max_difference`: [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.

- `lower_limit`: [in] The initial lower limit.

void **wait**(*std*::int64_t *upper_limit*)
Wait for the semaphore to be signaled.

Parameters
- `upper_limit`: [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower_limit which was set by *signal()* is larger than the max_difference.

bool **try_wait**(*std*::int64_t *upper_limit* = 1)
Try to wait for the semaphore to be signaled.

Return The function returns true if the calling thread would not block if it was calling *wait()*.
Parameters
- `upper_limit`: [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower_limit which was set by *signal()* is larger than the max_difference.

void **signal**(*std*::int64_t *lower_limit*)
Signal the semaphore.

Parameters
- `lower_limit`: [in] The new lower limit. This will update the current lower limit of this semaphore. It will also re-schedule all suspended threads for which their associated upper limit is not larger than the lower limit plus the max_difference.

tag_invoke

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace util

Typedefs

template<typename **F**, typename ...**Ts**>
using invoke_result_t = **typename** invoke_result<*F*, *Ts*...>::type

namespace hpx

namespace functional

Typedefs

template<typename **Tag**, typename ...**Args**>
using tag_invoke_result = invoke_result<decltype(*tag_invoke*), *Tag*, *Args*...>
`hpx::functional::tag_invoke_result<Tag, Args...>` is the trait returning the result type of the call hpx::functional::tag_invoke. This can be used in a SFINAE context.

template<typename **Tag**, typename ...**Args**>
using tag_invoke_result_t = **typename** *tag_invoke_result*<*Tag*, *Args*...>::type
`hpx::functional::tag_invoke_result_t<Tag, Args...>` evaluates to `hpx::functional::tag_invoke_result_t<Tag, Args...>::type`

Variables

constexpr unspecified **tag_invoke** = unspecified
The `hpx::functional::tag_invoke` name defines a constexpr object that is invocable with one or more arguments. The first argument is a 'tag' (typically a CPO). It is only invocable if an overload of tag_invoke() that accepts the same arguments could be found via ADL.

The evaluation of the expression `hpx::tag_invoke(tag, args...)` is equivalent to evaluating the unqualified call to `tag_invoke(decay-copy(tag), HPX_FORWARD(Args, args)...)`.

`hpx::functional::tag_invoke` is implemented against P1895.

Example: Defining a new customization point `foo`:

```
namespace mylib {
    inline constexpr
        struct foo_fn final : hpx::functional::tag<foo_fn>
        {
        } foo{};
}
```

Defining an object `bar` which customizes `foo`:

```
struct bar
{
    int x = 42;

    friend constexpr int tag_invoke(mylib::foo_fn, bar const& x)
    {
        return b.x;
    }
};
```

Using the customization point:

```
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```

template<typename **Tag**, typename ...**Args**>
constexpr bool **is_tag_invocable_v** = *is_tag_invocable<Tag, Args...>*::value
`hpx::functional::is_tag_invocable_v<Tag, Args...>` evaluates to *`hpx::functional::is_tag_invocable`*`<Tag, Args...>::value`

template<typename **Tag**, typename ...**Args**>
constexpr bool **is_nothrow_tag_invocable_v** = *is_nothrow_tag_invocable<Tag, Args...>*::value
`hpx::functional::is_tag_invocable_v<Tag, Args...>` evaluates to *`hpx::functional::is_tag_invocable`*`<Tag, Args...>::value`

template<typename **Tag**, typename ...**Args**>
struct is_nothrow_tag_invocable
#include <tag_invoke.hpp> *`hpx::functional::is_nothrow_tag_invocable`*`<Tag, Args...>` is std::true_type if an overload of `tag_invoke(tag, args...)` can be found via ADL and is noexcept.

template<typename **Tag**, typename ...**Args**>
struct is_tag_invocable
#include <tag_invoke.hpp> *`hpx::functional::is_tag_invocable`*`<Tag, Args...>` is std::true_type if an overload of `tag_invoke(tag, args...)` can be found via ADL.

template<typename **Tag**>
struct tag
#include <tag_invoke.hpp> *`hpx::functional::tag`*`<Tag>` defines a base class that implements the necessary tag dispatching functionality for a given type `Tag`

template<typename **Tag**>
struct tag_noexcept
#include <tag_invoke.hpp> *`hpx::functional::tag_noexcept`*`<Tag>` defines a base class that implements the necessary tag dispatching functionality for a given type `Tag` The implementation has to be noexcept

namespace hpx

Variables

template<typename **F**, typename ...**Ts**>
constexpr bool **is_invocable_v** = is_invocable<*F*, *Ts*...>::value

template<typename **R**, typename **F**, typename ...**Ts**>
constexpr bool **is_invocable_r_v** = is_invocable_r<*R*, *F*, *Ts*...>::value

thread_pool_util

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace threads

Functions

hpx::future<void> **resume_processing_unit**(*thread_pool_base* &*pool*, *std*::size_t *virt_core*)

Resumes the given processing unit. When the processing unit has been resumed the returned future will be ready.

Note Can only be called from an HPX thread. Use resume_processing_unit_cb or to resume the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.

Return A `future<void>` which is ready when the given processing unit has been resumed.

Parameters

- `virt_core`: [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

void **resume_processing_unit_cb**(*thread_pool_base* &*pool*, *hpx*::function<void) void > *callback*, *std*::size_t *virt_core*, *error_code* &*ec* = *throws*Resumes the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been resumed.

Note Requires that the pool has threads::policies::enable_elasticity set.

Parameters

- `callback`: [in] Callback which is called when the processing unit has been suspended.
- `virt_core`: [in] The processing unit to resume.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<void> **suspend_processing_unit**(*thread_pool_base* &*pool*, *std*::size_t *virt_core*)

Suspends the given processing unit. When the processing unit has been suspended the returned future will be ready.

Note Can only be called from an HPX thread. Use suspend_processing_unit_cb or to suspend the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.

Return A `future<void>` which is ready when the given processing unit has been suspended.

Parameters

- `virt_core`: [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

Exceptions

- `hpx::exception`: if called from outside the HPX runtime.

void **`suspend_processing_unit_cb`**(*hpx*::function<void) void
> *callback*, *thread_pool_base &pool*, *std*::size_t *virt_core*, *error_code &ec* = *throws*Suspends the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been suspended.

Note Requires that the pool has threads::policies::enable_elasticity set.

Parameters

- `callback`: [in] Callback which is called when the processing unit has been suspended.
- `virt_core`: [in] The processing unit to suspend.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<void> **`resume_pool`**(*thread_pool_base &pool*)
Resumes the thread pool. When the all OS threads on the thread pool have been resumed the returned future will be ready.

Note Can only be called from an HPX thread. Use resume_cb or resume_direct to suspend the pool from outside HPX.

Return A `future<void>` which is ready when the thread pool has been resumed.

Exceptions

- `hpx::exception`: if called from outside the HPX runtime.

void **`resume_pool_cb`**(*thread_pool_base &pool*, *hpx*::function<void) void
> *callback*, *error_code &ec* = *throws*Resumes the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been resumed.

Parameters

- `callback`: [in] called when the thread pool has been resumed.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<void> **`suspend_pool`**(*thread_pool_base &pool*)
Suspends the thread pool. When the all OS threads on the thread pool have been suspended the returned future will be ready.

Note Can only be called from an HPX thread. Use suspend_cb or suspend_direct to suspend the pool from outside HPX. A thread pool cannot be suspended from an HPX thread running on the pool itself.

Return A `future<void>` which is ready when the thread pool has been suspended.

Exceptions

- `hpx::exception`: if called from outside the HPX runtime.

void **`suspend_pool_cb`**(*thread_pool_base &pool*, *hpx*::function<void) void
> *callback*, *error_code &ec* = *throws*Suspends the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been suspended.

Note A thread pool cannot be suspended from an HPX thread running on the pool itself.

Parameters

- `callback`: [in] called when the thread pool has been suspended.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Exceptions

- `hpx::exception`: if called from an HPX thread which is running on the pool itself.

namespace hpx

Functions

template<typename **F**>
constexpr *F* &&**annotated_function** (*F* &&*f*, char **const*** = nullptr)

Returns a function annotated with the given annotation.

Annotating includes setting the thread description per thread id.

Parameters

- `function`:

template<typename **F**>

namespace threads

Functions

template<typename **F**>
thread_function_type **make_thread_function**(*F &&f*)

template<typename **F**>
thread_function_type **make_thread_function_nullary**(*F &&f*)

threads::*thread_id_ref_type* **register_thread**(*threads*::*thread_init_data &data*, *threads*::*thread_pool_base *pool*, *error_code &ec = throws*)

Create a new *thread* using the given data.

Return This function will return the internal id of the newly created HPX-thread.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `data`: [in] The data to use for creating the thread.
- `pool`: [in] The thread pool to use for launching the work.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Exceptions

- `invalid_status`: if the runtime system has not been started yet.

threads::*thread_id_ref_type* **register_thread**(*threads*::*thread_init_data &data*, *error_code &ec = throws*)

Create a new *thread* using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

Return This function will return the internal id of the newly created HPX-thread.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `data`: [in] The data to use for creating the thread.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Exceptions

- `invalid_status`: if the runtime system has not been started yet.

thread_id_ref_type **register_work** (*threads*::*thread_init_data* &*data*, *threads*::*thread_pool_base* **pool*, *error_code* &*ec* = *throws*)

Create a new work item using the given data.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `data`: [in] The data to use for creating the thread.
- `pool`: [in] The thread pool to use for launching the work.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Exceptions

- `invalid_status`: if the runtime system has not been started yet.

thread_id_ref_type **register_work** (*threads*::*thread_init_data* &*data*, *error_code* &*ec* = *throws*)

Create a new work item using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `data`: [in] The data to use for creating the thread.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Exceptions

- `invalid_status`: if the runtime system has not been started yet.

HPX_SCHEDULER_MODE_UNSCOPED_ENUM_DEPRECATION_MSG

namespace hpx

namespace threads

namespace policies

Enums

enum scheduler_mode

This enumeration describes the possible modes of a scheduler.

Values:

nothing_special = 0x0000

As the name suggests, this option can be used to disable all other options.

do_background_work = 0x0001

The scheduler will periodically call a provided callback function from a special HPX thread to enable performing background-work, for instance driving networking progress or garbage-collect AGAS.

reduce_thread_priority = 0x0002

The kernel priority of the os-thread driving the scheduler will be reduced below normal.

delay_exit = 0x0004

The scheduler will wait for some unspecified amount of time before exiting the scheduling loop while being terminated to make sure no other work is being scheduled during processing the shutdown request.

fast_idle_mode = 0x0008

Some schedulers have the capability to act as 'embedded' schedulers. In this case it needs to periodically invoke a provided callback into the outer scheduler more frequently than normal. This option enables this behavior.

enable_elasticity = 0x0010

This option allows for the scheduler to dynamically increase and reduce the number of processing units it runs on. Setting this value not succeed for schedulers that do not support this functionality.

enable_stealing = 0x0020

This option allows schedulers that support work thread/stealing to enable/disable it

enable_stealing_numa = 0x0040

This option allows schedulersthat support it to disallow stealing between numa domains

assign_work_round_robin = 0x0080

This option tells schedulersthat support it to add tasks round robin to queues on each core

assign_work_thread_parent = 0x0100

This option tells schedulers that support it to add tasks round to the same core/queue that the parent task is running on

steal_high_priority_first = 0x0200
This option tells schedulers that support it to always (try to) steal high priority tasks from other queues before finishing their own lower priority tasks

steal_after_local = 0x0400
This option tells schedulers that support it to steal tasks only when their local queues are empty

enable_idle_backoff = 0x0800
This option allows for certain schedulers to explicitly disable exponential idle-back off

default_ = *do_background_work* | *reduce_thread_priority* | *delay_exit* | *enable_stealing* | *enable_stealing_numa*
This option represents the default mode.

all_flags = *do_background_work* | *reduce_thread_priority* | *delay_exit* | *fast_idle_mode* | *enable_elasticity* | *en*
This enables all available options.

Functions

thread_data ***get_self_id_data**()
The function *get_self_id_data* returns the data of the HPX thread id associated with the current thread (or nullptr if the current thread is not a HPX thread).

thread_data ***get_thread_id_data**(*thread_id_ref_type* **const** &*tid*)

thread_data ***get_thread_id_data**(thread_id_type **const** &*tid*)

thread_self &**get_self**()
The function *get_self* returns a reference to the (OS thread specific) self reference to the current HPX thread.

thread_self ***get_self_ptr**()
The function *get_self_ptr* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_self_impl_type ***get_ctx_ptr**()
The function *get_ctx_ptr* returns a pointer to the internal data associated with each coroutine.

thread_self ***get_self_ptr_checked**(*error_code* &*ec* = *throws*)
The function *get_self_ptr_checked* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_id_type **get_self_id**()
The function *get_self_id* returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

thread_id_type **get_parent_id**()
The function *get_parent_id* returns the HPX thread id of the current thread's parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::size_t **get_parent_phase**()
The function *get_parent_phase* returns the HPX phase of the current thread's parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::ptrdiff_t **get_self_stacksize**()
The function *get_self_stacksize* returns the stack size of the current thread (or zero if the current thread is not a HPX thread).

thread_stacksize **get_self_stacksize_enum**()
The function *get_self_stacksize_enum* returns the stack size of the /.

std::uint32_t **get_parent_locality_id**()
The function *get_parent_locality_id* returns the id of the locality of the current thread's parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::uint64_t **get_self_component_id**()
The function *get_self_component_id* returns the lva of the component the current thread is acting on

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_TARGET_ADDRESS being defined.

class thread_data : **public** thread_data_reference_counting
#include <thread_data.hpp> A *thread* is the representation of a ParalleX thread. It's a first class object in ParalleX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the *thread-manager*.

A *thread* encapsulates:
- A thread status word (see the functions *thread::get_state* and *thread::set_state*)
- A function to execute (the thread function)
- A frame (in this implementation this is a block of memory used as the threads stack)
- A block of registers (not implemented yet)

Generally, *threads* are not created or executed directly. All functionality related to the management of *threads* is implemented by the thread-manager.

Subclassed by *hpx::threads::thread_data_stackful*, *hpx::threads::thread_data_stackless*

Public Types

using spinlock_pool = *util*::spinlock_pool<*thread_data*>

Public Functions

thread_data(*thread_data* **const**&)

thread_data(*thread_data*&&)

thread_data &**operator=**(*thread_data* **const**&)

thread_data &**operator=**(*thread_data*&&)

thread_state **get_state**(*std*::memory_order *order* = *std*::memory_order_acquire) **const**
The get_state function queries the state of this thread instance.

Return This function returns the current state of this thread. It will return one of the values as defined by the *thread_state* enumeration.
Note This function will be seldom used directly. Most of the time the state of a thread will be retrieved by using the function *threadmanager::get_state*.

thread_state **set_state**(*thread_schedule_state state*, *thread_restart_state state_ex* = *thread_restart_state*::unknown, *std*::memory_order *load_order* = *std*::memory_order_acquire, *std*::memory_order *exchange_order* = *std*::memory_order_seq_cst)

The set_state function changes the state of this thread instance.

Note This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status *threadmanager::set_state* should be used.

Parameters

- `newstate`: [in] The new state to be set for the thread.

bool **set_state_tagged**(*thread_schedule_state newstate*, thread_state &*prev_state*, thread_state &*new_tagged_state*, *std*::memory_order *exchange_order* = *std*::memory_order_seq_cst)

bool **restore_state**(thread_state *new_state*, thread_state *old_state*, *std*::memory_order *load_order* = *std*::memory_order_relaxed, *std*::memory_order *load_exchange* = *std*::memory_order_seq_cst)

The restore_state function changes the state of this thread instance depending on its current state. It will change the state atomically only if the current state is still the same as passed as the second parameter. Otherwise it won't touch the thread state of this instance.

Note This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status *threadmanager::set_state* should be used.

Return This function returns *true* if the state has been changed successfully

Parameters

- `newstate`: [in] The new state to be set for the thread.
- `oldstate`: [in] The old state of the thread which still has to be the current state.

bool **restore_state**(*thread_schedule_state new_state*, *thread_restart_state state_ex*, thread_state *old_state*, *std*::memory_order *load_exchange* = *std*::memory_order_seq_cst)

constexpr *std*::uint64_t **get_component_id**() **const**

Return the id of the component this thread is running in.

util::*thread_description* **get_description**() **const**

Protected Functions

thread_restart_state **set_state_ex**(*thread_restart_state new_state*)

The set_state function changes the extended state of this thread instance.

Note This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager.

Parameters

- `newstate`: [in] The new extended state to be set for the thread.

void **rebind_base**(*thread_init_data &init_data*)

namespace hpx

namespace threads

class thread_data_stackful : **public** *hpx*::*threads*::*thread_data*

#include <thread_data_stackful.hpp> A *thread* is the representation of a ParalleX thread. It's a first class object in ParalleX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the *thread-manager*.

A *thread* encapsulates:

- A thread status word (see the functions *thread::get_state* and *thread::set_state*)
- A function to execute (the thread function)
- A frame (in this implementation this is a block of memory used as the threads stack)

- A block of registers (not implemented yet)

Generally, *threads* are not created or executed directly. All functionality related to the management of *threads* is implemented by the thread-manager.

Functions

util::*thread_description* **get_thread_description**(thread_id_type **const** &*id*, *error_code* &*ec* = *throws*)

The function get_thread_description is part of the thread related API allows to query the description of one of the threads known to the thread-manager.

Return This function returns the description of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the string "<unknown>".

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread being queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

util::*thread_description* **set_thread_description**(thread_id_type **const** &*id*, *util*::*thread_description* **const** &*desc* = *util*::*thread_description*(), *error_code* &*ec* = *throws*)

Functions

threads::*thread_restart_state* **suspend**(*threads*::*thread_schedule_state* *state*, *threads*::thread_id_type *id*, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

Note Must be called from within a HPX-thread.

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_restart_state* **suspend**(*threads*::*thread_schedule_state* *state* = *threads*::*thread_schedule_state*::pending, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

Note Must be called from within a HPX-thread.

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_restart_state* **suspend**(*hpx*::*chrono*::*steady_time_point* **const** &*abs_time*, *threads*::thread_id_type *id*, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

Note Must be called from within a HPX-thread.

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_restart_state* **suspend**(*hpx*::*chrono*::*steady_time_point* **const** &*abs_time*, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

Note Must be called from within a HPX-thread.

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_restart_state* **suspend**(*hpx*::*chrono*::*steady_duration* **const** &*rel_time*, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

Note Must be called from within a HPX-thread.
Exceptions
- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_restart_state* **suspend**(*hpx*::*chrono*::*steady_duration* **const** &*rel_time*, *threads*::thread_id_type **const** &*id*, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

Note Must be called from within a HPX-thread.
Exceptions
- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_restart_state* **suspend**(*std*::uint64_t *ms*, *util*::*thread_description* **const** &*description* = *util*::*thread_description*("this_thread::suspend"), *error_code* &*ec* = *throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given time (specified in milliseconds).

Note Must be called from within a HPX-thread.
Exceptions
- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

threads::*thread_pool_base* ***get_pool**(*error_code* &*ec* = *throws*)

Returns a pointer to the pool that was used to run the current thread

Exceptions
- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of

hpx::yield_aborted if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

namespace threads

Functions

thread_state **set_thread_state**(thread_id_type **const** *&id*, *thread_schedule_state state* = *thread_schedule_state*::pending, *thread_restart_state stateex* = *thread_restart_state*::signaled, *thread_priority priority* = *thread_priority*::normal, bool *retry_on_active* = true, *hpx*::*error_code &ec* = *throws*)

Set the thread state of the *thread* referenced by the thread_id *id*.

Note If the thread referenced by the parameter *id* is in *thread_state::active* state this function schedules a new thread which will set the state of the thread as soon as its not active anymore. The function returns *thread_state::active* in this case.

Return This function returns the previous state of the thread referenced by the *id* parameter. It will return one of the values as defined by the *thread_state* enumeration. If the thread is not known to the thread-manager the return value will be *thread_state::unknown*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread the state should be modified for.
- `state`: [in] The new state to be set for the thread referenced by the *id* parameter.
- `stateex`: [in] The new extended state to be set for the thread referenced by the *id* parameter.
- `priority`:
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

thread_id_ref_type **set_thread_state**(thread_id_type **const** *&id*, *hpx*::*chrono*::*steady_time_point* **const** *&abs_time*, *std*::atomic<bool> **started*, *thread_schedule_state state* = *thread_schedule_state*::pending, *thread_restart_state stateex* = *thread_restart_state*::timeout, *thread_priority priority* = *thread_priority*::normal, bool *retry_on_active* = true, *error_code &ec* = *throws*)

Set the thread state of the *thread* referenced by the thread_id *id*.

Set a timer to set the state of the given *thread* to the given new value after it expired (at the given time)

Return

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread the state should be modified for.
- `abs_time`: [in] Absolute point in time for the new thread to be run
- `started`: [in,out] A helper variable allowing to track the state of the timer helper thread
- `state`: [in] The new state to be set for the thread referenced by the *id* parameter.
- `stateex`: [in] The new extended state to be set for the thread referenced by the *id* parameter.
- `priority`:

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

thread_id_ref_type **set_thread_state**(thread_id_type **const** *&id*, *hpx::chrono::steady_time_point* **const** *&abs_time*, *thread_schedule_state state* = *thread_schedule_state*::pending, *thread_restart_state stateex* = *thread_restart_state*::timeout, *thread_priority priority* = *thread_priority*::normal, bool *retry_on_active* = true, *error_code*& = *throws*)

thread_id_ref_type **set_thread_state**(thread_id_type **const** *&id*, *hpx::chrono::steady_duration* **const** *&rel_time*, *thread_schedule_state state* = *thread_schedule_state*::pending, *thread_restart_state stateex* = *thread_restart_state*::timeout, *thread_priority priority* = *thread_priority*::normal, bool *retry_on_active* = true, *error_code &ec* = *throws*)

Set the thread state of the *thread* referenced by the thread_id *id*.

Set a timer to set the state of the given *thread* to the given new value after it expired (after the given duration)

Return

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread the state should be modified for.
- `rel_time`: [in] Time duration after which the new thread should be run
- `state`: [in] The new state to be set for the thread referenced by the *id* parameter.
- `stateex`: [in] The new extended state to be set for the thread referenced by the *id* parameter.
- `priority`:
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

thread_state **get_thread_state**(thread_id_type **const** *&id*, *error_code &ec* = *throws*)

The function get_thread_backtrace is part of the thread related API allows to query the currently stored thread back trace (which is captured during thread suspension).

Return This function returns the currently captured stack back trace of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception. The function get_thread_state is part of the thread related API. It queries the state of one of the threads known to the thread-manager.

Return This function returns the thread state of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be *terminated*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread being queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Parameters

- `id`: [in] The thread id of the thread the state should be modified for.

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::size_t **`get_thread_phase`**(thread_id_type **`const`** *&id*, *error_code &ec = throws*)

The function get_thread_phase is part of the thread related API. It queries the phase of one of the threads known to the thread-manager.

Return This function returns the thread phase of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be ~0.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread the phase should be modified for.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`get_thread_interruption_enabled`**(thread_id_type **`const`** *&id*, *error_code &ec = throws*)

Returns whether the given thread can be interrupted at this point.

Return This function returns *true* if the given thread can be interrupted at this point in time. It will return *false* otherwise.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread which should be queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`set_thread_interruption_enabled`**(thread_id_type **`const`** *&id*, bool *enable*, *error_code &ec = throws*)

Set whether the given thread can be interrupted at this point.

Return This function returns the previous value of whether the given thread could have been interrupted.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread which should receive the new value.
- `enable`: [in] This value will determine the new interruption enabled status for the given thread.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`get_thread_interruption_requested`**(thread_id_type **`const`** *&id*, *error_code &ec = throws*)

Returns whether the given thread has been flagged for interruption.

Return This function returns *true* if the given thread was flagged for interruption. It will return *false* otherwise.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread which should be queried.

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`interrupt_thread`**(thread_id_type **`const`** &*id*, bool *flag*, *error_code* &*ec* = *throws*)

Flag the given thread for interruption.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread which should be interrupted.
- `flag`: [in] The flag encodes whether the thread should be interrupted (if it is *true*), or 'uninterrupted' (if it is *false*).
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`interrupt_thread`**(thread_id_type **`const`** &*id*, *error_code* &*ec* = *throws*)

void **`interruption_point`**(thread_id_type **`const`** &*id*, *error_code* &*ec* = *throws*)

Interrupt the current thread at this point if it was canceled. This will throw a thread_interrupted exception, which will cancel the thread.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread which should be interrupted.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

threads::*thread_priority* **`get_thread_priority`**(thread_id_type **`const`** &*id*, *error_code* &*ec* = *throws*)

Return priority of the given thread

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread whose priority is queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::ptrdiff_t **`get_stack_size`**(thread_id_type **`const`** &*id*, *error_code* &*ec* = *throws*)

Return stack size of the given thread

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The thread id of the thread whose priority is queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

threads::*thread_pool_base* ***`get_pool`**(thread_id_type **`const`** &*id*, *error_code* &*ec* = *throws*)

Returns a pointer to the pool that was used to run the current thread

Exceptions

- `If: &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield_aborted* if it is signaled with *wait_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid_status*.

Functions

std::size_t **get_worker_thread_num**()

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by *get_os_thread_count()*.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t **get_worker_thread_num**(*error_code &ec*)

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by *get_os_thread_count()*. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

std::size_t **get_local_worker_thread_num**()

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t **get_local_worker_thread_num**(*error_code &ec*)

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

std::size_t **get_thread_pool_num**()

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t **get_thread_pool_num**(*error_code &ec*)

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

namespace hpx

namespace threads

Functions

std::ostream &**operator<<**(*std*::ostream *&os*, *thread_pool_base* **const** *&thread_pool*)

class thread_pool_base

#include <thread_pool_base.hpp> The base class used to manage a pool of OS threads.

Public Functions

virtual void **suspend_processing_unit_direct**(*std*::size_t *virt_core*, *error_code &ec = throws*) = 0

Suspends the given processing unit. Blocks until the processing unit has been suspended.

Parameters

- `virt_core`: [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

virtual void **resume_processing_unit_direct**(*std*::size_t *virt_core*, *error_code &ec = throws*) = 0

Resumes the given processing unit. Blocks until the processing unit has been resumed.

Parameters

- `virt_core`: [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

virtual void **resume_direct**(*error_code &ec = throws*) = 0

Resumes the thread pool. Blocks until all OS threads on the thread pool have been resumed.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **suspend_direct**(*error_code &ec = throws*) = 0

Suspends the thread pool. Blocks until all OS threads on the thread pool have been suspended.

Note A thread pool cannot be suspended from an HPX thread running on the pool itself.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Exceptions

- `hpx::exception`: if called from an HPX thread which is running on the pool itself.

threadmanager

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace threads

class threadmanager

#include <threadmanager.hpp> The *thread-manager* class is the central instance of management for all (non-depleted) threads

Public Types

typedef *threads*::*policies*::*callback_notifier* **notification_policy_type**

typedef *std*::unique_ptr<*thread_pool_base*> **pool_type**

typedef *threads*::*policies*::*scheduler_base* **scheduler_type**

typedef *std*::vector<*pool_type*> **pool_vector**

Public Functions

threadmanager(*hpx::util::runtime_configuration &rtcfg_*, *notification_policy_type &notifier*, detail::network_background_callback_type *network_background_callback* = detail::network_background_callback_type())

~threadmanager()

void **init**()

void **create_pools**()

void **print_pools**(*std*::ostream&)

FIXME move to private and add hpx:printpools cmd line option.

thread_pool_base &**default_pool**() **const**

scheduler_type &**default_scheduler**() **const**

thread_pool_base &**get_pool**(*std*::string **const** &*pool_name*) **const**

thread_pool_base &**get_pool**(pool_id_type **const** &*pool_id*) **const**

thread_pool_base &**get_pool**(*std*::size_t *thread_index*) **const**

bool **pool_exists**(*std*::string **const** &*pool_name*) **const**

bool **pool_exists**(*std*::size_t *pool_index*) **const**

thread_id_ref_type **register_work**(*thread_init_data &data*, *error_code &ec* = *throws*)

The function *register_work* adds a new work item to the thread manager. It doesn't immediately create a new *thread*, it just adds the task parameters (function, initial state and description) to the internal management data structures. The thread itself will be created when the number of existing threads drops below the number of threads specified by the constructors max_count parameter.

Parameters

- `func`: [in] The function or function object to execute as the thread's function. This must have a signature as defined by *thread_function_type*.
- `description`: [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

void **register_thread**(*thread_init_data &data*, *thread_id_ref_type &id*, *error_code &ec* = *throws*)

The function *register_thread* adds a new work item to the thread manager. It creates a new *thread*, adds it to the internal management data structures, and schedules the new thread, if appropriate.

Parameters

- `func`: [in] The function or function object to execute as the thread's function. This must have a signature as defined by *thread_function_type*.
- `id`: [out] This parameter will hold the id of the created thread. This id is guaranteed to be validly initialized before the thread function is executed.
- `description`: [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

bool **run**()
Run the thread manager's work queue. This function instantiates the specified number of OS threads in each pool. All OS threads are started to execute the function *tfunc*.

Return The function returns *true* if the thread manager has been started successfully, otherwise it returns *false*.

void **stop**(bool *blocking* = true)
Forcefully stop the thread-manager.

Parameters
- `blocking`:

bool **is_busy**()

bool **is_idle**()

void **wait**()

void **suspend**()

void **resume**()

state **status**() **const**
Return whether the thread manager is still running This returns the "minimal state", i.e. the state of the least advanced thread pool.

std::int64_t **get_thread_count**(*thread_schedule_state state* = *thread_schedule_state*::unknown, *thread_priority priority* = *thread_priority*::default_, *std*::size_t *num_thread* = *std*::size_t(-1), bool *reset* = false)
return the number of HPX-threads with the given state

Note This function lock the internal OS lock in the thread manager

std::int64_t **get_idle_core_count**()

mask_type **get_idle_core_mask**()

std::int64_t **get_background_thread_count**()

bool **enumerate_threads**(*hpx*::function<bool) thread_id_type > **const** &*f*, *thread_schedule_state state* = *thread_schedule_state*::unknown **const**

void **abort_all_suspended_threads**()

bool **cleanup_terminated**(bool *delete_all*)

std::size_t **get_os_thread_count**() **const**
Return the number of OS threads running in this thread-manager.

This function will return correct results only if the thread-manager is running.

std::thread &**get_os_thread_handle**(*std*::size_t *num_thread*) **const**

void **report_error**(*std*::size_t *num_thread*, *std*::exception_ptr **const** &*e*)
API functions forwarding to notification policy.

This notifies the thread manager that the passed exception has been raised. The exception will be routed through the notifier and the scheduler (which will result in it being passed to the runtime object, which in turn will report it to the console, etc.).

mask_type **get_used_processing_units**() **const**
Returns the mask identifying all processing units used by this thread manager.

hwloc_bitmap_ptr **get_pool_numa_bitmap**(**const** *std*::string &*pool_name*) **const**

void **set_scheduler_mode**(*threads*::*policies*::*scheduler_mode mode*)

void **add_scheduler_mode**(*threads*::*policies*::*scheduler_mode mode*)

void **add_remove_scheduler_mode**(*threads*::*policies*::*scheduler_mode to_add_mode*, *threads*::*policies*::*scheduler_mode to_remove_mode*)

void **remove_scheduler_mode**(*threads*::*policies*::*scheduler_mode mode*)

void **reset_thread_distribution**()

void **init_tss**(*std*::size_t *global_thread_num*)

void **deinit_tss**()

std::int64_t **get_queue_length**(bool *reset*)

std::int64_t **get_cumulative_duration**(bool *reset*)

std::int64_t **get_thread_count_unknown**(bool *reset*)

std::int64_t **get_thread_count_active**(bool *reset*)

std::int64_t **get_thread_count_pending**(bool *reset*)

std::int64_t **get_thread_count_suspended**(bool *reset*)

std::int64_t **get_thread_count_terminated**(bool *reset*)

std::int64_t **get_thread_count_staged**(bool *reset*)

struct async_execute_after_t : **public** *hpx*::*functional*::detail::tag_fallback<*async_execute_after_t*>

#include <*timed_execution_fwd.hpp*> Customization point of asynchronous execution agent creation supporting timed execution.

This asynchronously creates a single function invocation f() using the associated executor at the given point in time.

Return f(ts...)'s result through a future

Note This calls exec.async_execute_after(rel_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::async_execute() on the underlying non-time-scheduled execution agent.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `rel_time`: [in] The duration of time after which the given function should be scheduled to run.
- `f`: [in] The function which will be scheduled using the given executor.
- `ts...`: [in] Additional arguments to use to invoke *f*.

Private Functions

template<typename **Executor**, typename **F**, typename ...**Ts**>
decltype(auto) **friend tag_fallback_invoke**(*async_execute_after_t*, *Executor* &&*exec*, *hpx*::*chrono*::*steady_duration* **const** &*rel_time*, *F* &&*f*, *Ts*&&... *ts*)

struct async_execute_at_t : **public** *hpx*::*functional*::detail::tag_fallback<*async_execute_at_t*>

#include <*timed_execution_fwd.hpp*> Customization point of asynchronous execution agent creation supporting timed execution.

This asynchronously creates a single function invocation f() using the associated executor at the given point in time.

Return f(ts...)'s result through a future

Note This calls exec.async_execute_at(abs_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::async_execute() on the underlying non-time-scheduled execution agent.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function *f*.
- `abs_time`: [in] The point in time the given function should be scheduled at to run.
- `f`: [in] The function which will be scheduled using the given executor.
- `ts...`: [in] Additional arguments to use to invoke *f*.

Private Functions

struct topology

Public Functions

topology()

~topology()

std::size_t **get_socket_number**(*std*::size_t *num_thread*, *error_code*& = *throws*) **const**

Return the Socket number of the processing unit the given thread is running on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::size_t **get_numa_node_number**(*std*::size_t *num_thread*, *error_code*& = *throws*) **const**

Return the NUMA node number of the processing unit the given thread is running on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **get_machine_affinity_mask**(*error_code* &*ec* = *throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit available to the application.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_type **get_service_affinity_mask**(mask_cref_type *used_processing_units*, *error_code* &*ec* = *throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit available to the service threads in the application.

Parameters

- `used_processing_units`: [in] This is the mask of processing units which are not available for service threads.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **get_socket_affinity_mask**(*std*::size_t *num_thread*, *error_code* &*ec* = *throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the socket it is running on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **get_numa_node_affinity_mask**(*std*::size_t *num_thread*, *error_code &ec = throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the NUMA domain it is running on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_type **get_numa_node_affinity_mask_from_numa_node**(*std*::size_t *num_node*) **const**

Return a bit mask where each set bit corresponds to a processing unit associated with the given NUMA node.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **get_core_affinity_mask**(*std*::size_t *num_thread*, *error_code &ec = throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the core it is running on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **get_thread_affinity_mask**(*std*::size_t *num_thread*, *error_code &ec = throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit available to the given thread.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **set_thread_affinity_mask**(mask_cref_type *mask*, *error_code &ec = throws*) **const**

Use the given bit mask to set the affinity of the given thread. Each set bit corresponds to a processing unit the thread will be allowed to run on.

Note Use this function on systems where the affinity must be set from inside the thread itself.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_type **get_thread_affinity_mask_from_lva**(void **const** **lva*, *error_code &ec = throws*) **const**

Return a bit mask where each set bit corresponds to a processing unit co-located with the memory the given address is currently allocated on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **print_affinity_mask**(*std*::ostream &*os*, *std*::size_t *num_thread*, mask_cref_type *m*, **const** *std*::string &*pool_name*) **const**

Prints the.

Parameters

- `m`: to os in a human readable form

bool **reduce_thread_priority**(*error_code* &*ec* = *throws*) **const**

Reduce thread priority of the current thread.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::size_t **get_number_of_sockets**() **const**

Return the number of available NUMA domains.

std::size_t **get_number_of_numa_nodes**() **const**

Return the number of available NUMA domains.

std::size_t **get_number_of_cores**() **const**

Return the number of available cores.

std::size_t **get_number_of_pus**() **const**

Return the number of available hardware processing units.

std::size_t **get_number_of_numa_node_cores**(*std*::size_t *numa*) **const**

Return number of cores in given numa domain.

std::size_t **get_number_of_numa_node_pus**(*std*::size_t *numa*) **const**

Return number of processing units in a given numa domain.

std::size_t **get_number_of_socket_pus**(*std*::size_t *socket*) **const**

Return number of processing units in a given socket.

std::size_t **get_number_of_core_pus**(*std*::size_t *core*) **const**

Return number of processing units in given core.

std::size_t **get_number_of_socket_cores**(*std*::size_t *socket*) **const**

Return number of cores units in given socket.

std::size_t **get_core_number**(*std*::size_t *num_thread*, *error_code*& = *throws*) **const**

std::size_t **get_pu_number**(*std*::size_t *num_core*, *std*::size_t *num_pu*, *error_code* &*ec* = *throws*) **const**

mask_type **get_cpubind_mask**(*error_code* &*ec* = *throws*) **const**

mask_type **get_cpubind_mask**(*std*::thread &*handle*, *error_code* &*ec* = *throws*) **const**

hwloc_bitmap_ptr **cpuset_to_nodeset**(mask_cref_type *cpuset*) **const**

convert a cpu mask into a numa node mask in hwloc bitmap form

void **write_to_log**() **const**

void ***allocate**(*std*::size_t *len*) **const**
This is equivalent to malloc(), except that it tries to allocate page-aligned memory from the OS.

void ***allocate_membind**(*std*::size_t *len*, *hwloc_bitmap_ptr* *bitmap*, *hpx_hwloc_membind_policy* *policy*, int *flags*) **const**
allocate memory with binding to a numa node set as specified by the policy and flags (see hwloc docs)

threads::mask_type **get_area_membind_nodeset**(**const** void **addr*, *std*::size_t *len*) **const**

bool **set_area_membind_nodeset**(**const** void **addr*, *std*::size_t *len*, void **nodeset*) **const**

int **get_numa_domain**(**const** void **addr*) **const**

void **deallocate**(void **addr*, *std*::size_t *len*) **const**
Free memory that was previously allocated by allocate.

void **print_vector**(*std*::ostream &*os*, *std*::vector<*std*::size_t> **const** &*v*) **const**

void **print_mask_vector**(*std*::ostream &*os*, *std*::vector<mask_type> **const** &*v*) **const**

template<typename **Iterator**>
bool **insert_checked** (*std*::pair<*Iterator*, bool> **const** &*r*)

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

Return This function returns **r.second**.

Parameters

- `r`: [in] The return value of a std::map insert operation.

template<typename **Iterator**>
bool **insert_checked** (*std*::pair<*Iterator*, bool> **const** &*r*, *Iterator* &*it*)

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

Return This function returns **r.second**.
Parameters
- `r`: [in] The return value of a std::map insert operation.
- `r`: [out] A reference to an Iterator, which is set to **r.first**.

bool **parse_sed_expression**(*std*::string **const** &*input*, *std*::string &*search*, *std*::string &*replace*)

Parse a sed command.

Return *true* if the parsing was successful, false otherwise.
Note Currently, only supports search and replace syntax (s/search/replace/)
Parameters

- `input`: [in] The content to parse.
- `search`: [out] If the parsing is successful, this string is set to the search expression.
- `search`: [out] If the parsing is successful, this string is set to the replace expression.

struct sed_transform

#include <sed_transform.hpp> An unary function object which applies a sed command to its subject and returns the resulting string.

Note Currently, only supports search and replace syntax (s/search/replace/)

Public Functions

Defines

HPX_REGISTER_ACTION_DECLARATION(...)

Declare the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION_DECLARATION* can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
```

(continues on next page)

(continued from previous page)

```
        HPX_DEFINE_COMPONENT_ACTION(server,
            print_greeting, print_greeting_action);
    };
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action)
```

Example:

Note This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* macros. It has to be visible in all translation units using the action, thus it is recommended to place it into the header file defining the component.

HPX_REGISTER_ACTION_DECLARATION_(...)

HPX_REGISTER_ACTION_DECLARATION_1(*action*)

HPX_REGISTER_ACTION(...)

Define the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

Note This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

HPX_REGISTER_ACTION_ID(*action*, *actionname*, *actionid*)

Define the necessary component action boilerplate code and assign a predefined unique id to the action.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

The parameter *actionname* specifies an unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

The parameter *actionid* specifies an unique integer value which will be used to represent the action during serialization.

Note This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or global actions *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

namespace hpx

namespace actions

template<typename **Component**, typename **Signature**, typename **Derived**>
struct basic_action

#include <basic_action_fwd.hpp>

Template Parameters

- `Component`: component type
- `Signature`: return type and arguments
- `Derived`: derived action class

Defines

HPX_DEFINE_COMPONENT_ACTION(...)

Registers a member function of a component as an action type with HPX.

The macro *HPX_DEFINE_COMPONENT_ACTION* can be used to register a member function of a component as an action type named *action_type*.

The parameter *component* is the type of the component exposing the member function *func* which should be associated with the newly defined action type. The parameter `action_type` is the name of the action type to register with HPX.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting() const
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting,
            print_greeting_action);
    };
}
```

Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending '_action'. The third argument can be omitted only if the second argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

Note The macro *HPX_DEFINE_COMPONENT_ACTION* can be used with 2 or 3 arguments. The third argument is optional.

Defines

HPX_DEFINE_PLAIN_ACTION(...)

Defines a plain action type.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // This will define the action type 'app::some_global_action' which
    // represents the function 'app::some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
```

Example:

Note Usually this macro will not be used in user code unless the intent is to avoid defining the action_type in global namespace. Normally, the use of the macro *HPX_PLAIN_ACTION* is recommended.

Note The macro *HPX_DEFINE_PLAIN_ACTION* can be used with 1 or 2 arguments. The second argument is optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

HPX_DECLARE_PLAIN_ACTION(...)

Declares a plain action type.

HPX_PLAIN_ACTION(...)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX_PLAIN_ACTION* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *name* representing the given function. This macro additionally registers the newly define action type with HPX.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action)
```

Example:

Note The macro *HPX_PLAIN_ACTION* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

Note The macro *HPX_PLAIN_ACTION_ID* can be used with 1, 2, or 3 arguments. The second and third arguments are optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name. The default value for the third argument is *hpx::components::factory_check*.

Note Only one of the forms of this macro *HPX_PLAIN_ACTION* or *HPX_PLAIN_ACTION_ID* should be used for a particular action, never both.

HPX_PLAIN_ACTION_ID (*func*, *name*, *id*)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX_PLAIN_ACTION_ID* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *actionname* representing the given function. The parameter *actionid*

The parameter *actionid* specifies an unique integer value which will be used to represent the action during serialization.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,
  some_unique_id);
```

Example:

Note The macro *HPX_PLAIN_ACTION_ID* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

Note Only one of the forms of this macro *HPX_PLAIN_ACTION* or *HPX_PLAIN_ACTION_ID* should be used for a particular action, never both.

bool **register_locality** (*parcelset*::*endpoints_type* **const** &*endpoints*, *naming*::*gid_type* &*prefix*, *std*::uint32_t *num_threads*, *error_code* &*ec* = *throws*)

Add a locality to the runtime.

parcelset::*endpoints_type* **const** &**resolve_locality** (*naming*::*gid_type* **const** &*gid*, *error_code* &*ec* = *throws*)

Resolve a locality to its prefix.

Return Returns an empty vector if the locality is not registered.

bool **has_resolved_locality** (*naming*::*gid_type* **const** &*gid*)

bool **unregister_locality** (*naming*::*gid_type* **const** &*gid*, *error_code* &*ec* = *throws*)

Remove a locality from the runtime.

void **remove_resolved_locality** (*naming*::*gid_type* **const** &*gid*)

remove given locality from locality cache

bool **get_console_locality** (*naming*::*gid_type* &*locality*, *error_code* &*ec* = *throws*)

Get locality locality_id of the console locality.

Return This function returns *true* if a console locality_id exists and returns *false* otherwise.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `locality_id`: [out] The locality_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
- `try_cache`: [in] If this is set to true the console is first tried to be found in the local cache. Otherwise this function will always query AGAS, even if the console locality_id is already known locally.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **get_localities**(*std*::vector<*naming*::*gid_type*> &*locality_ids*, *components*::*component_type type*, *error_code* &*ec* = *throws*)

Query for the locality_ids of all known localities.

This function returns the locality_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `locality_ids`: [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime_support components of these localities.
- `type`: [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_invalid*, which will return prefixes of all localities.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **get_localities**(*std*::vector<*naming*::*gid_type*> &*locality_ids*, *error_code* &*ec* = *throws*)

hpx::future<*std*::uint32_t> **get_num_localities_async**(*components*::*component_type type* = *components*::*component_invalid*) **const**

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `type`: [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_invalid*, which will return prefixes of all localities.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::uint32_t **get_num_localities**(*components*::*component_type type*, *error_code* &*ec* = *throws*) **const**

std::uint32_t **get_num_localities**(*error_code* &*ec* = *throws*) **const**

hpx::future<*std*::uint32_t> **get_num_overall_threads_async**() **const**

std::uint32_t **get_num_overall_threads**(*error_code* &*ec* = *throws*) **const**

hpx::future<*std*::vector<*std*::uint32_t>> **get_num_threads_async**() **const**

std::vector<*std*::uint32_t> **get_num_threads**(*error_code* &*ec* = *throws*) **const**

components::*component_type* **get_component_id**(*std*::string **const** &*name*, *error_code* &*ec* = *throws*)

Return a unique id usable as a component type.

This function returns the component type id associated with the given component name. If this is the first request for this component name a new unique id will be created.

Return The function returns the currently associated component type. Any error results in an exception thrown from this function.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `name`: [in] The component name (string) to get the component type for.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`iterate_types`**(*iterate_types_function_type* **const** *&f*, *error_code &ec = throws*)

std::string **`get_component_type_name`**(*components*::*component_type id*, *error_code &ec = throws*)

components::*component_type* **`register_factory`**(*naming*::*gid_type* **const** *&locality_id*, *std*::string **const** *&name*, *error_code &ec = throws*)

Register a factory for a specific component type.

This function allows to register a component factory for a given locality and component type.

Return The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function *get_component_id* was called using the same component name.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `locality_id`: [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- `name`: [in] The component name (string) to register a factory for the given component type for.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

components::*component_type* **`register_factory`**(*std*::uint32_t *locality_id*, *std*::string **const** *&name*, *error_code &ec = throws*)

bool **`get_id_range`**(*std*::uint64_t *count*, *naming*::*gid_type &lower_bound*, *naming*::*gid_type &upper_bound*, *error_code &ec = throws*)

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

Return This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

Note This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling *bind* or *bind_range*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `l`: [in] The locality the locality id needs to be generated for. Repeating calls using the same locality results in identical locality_id values.
- `count`: [in] The number of global ids to be generated.
- `lower_bound`: [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
- `upper_bound`: [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **bind_local**(*naming*::*gid_type* **const** &*id*, *naming*::*address* **const** &*addr*, *error_code* &*ec* = *throws*)

Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.

Return This function returns *true*, if this global id got associated with an local address. It returns *false* otherwise.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note Binding a gid to a local address sets its global reference count to one.

Parameters

- `id`: [in] The global address which has to be bound to the local address.
- `addr`: [in] The local address to be bound to the global address.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<bool> **bind_async**(*naming*::*gid_type* **const** &*id*, *naming*::*address* **const** &*addr*, *std*::uint32_t *locality_id*)

hpx::future<bool> **bind_async**(*naming*::*gid_type* **const** &*id*, *naming*::*address* **const** &*addr*, *naming*::*gid_type* **const** &*locality*)

bool **bind_range_local**(*naming*::*gid_type* **const** &*lower_id*, *std*::uint64_t *count*, *naming*::*address* **const** &*baseaddr*, *std*::uint64_t *offset*, *error_code* &*ec* = *throws*)

Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given *offset*).

Return This function returns *true*, if the given range was successfully bound. It returns *false* otherwise.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note Binding a gid to a local address sets its global reference count to one.

Parameters

- `lower_id`: [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
- `count`: [in] The number of consecutive global ids to bind starting at *lower_id*.

- `baseaddr`: [in] The local address to bind to the global id given by *lower_id*. This is the base address for all additional local addresses to bind to the remaining global ids.
- `offset`: [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<bool> **bind_range_async**(*naming*::*gid_type* **const** &*lower_id*, *std*::uint64_t *count*, *naming*::*address* **const** &*baseaddr*, *std*::uint64_t *offset*, *naming*::*gid_type* **const** &*locality*)

hpx::future<bool> **bind_range_async**(*naming*::*gid_type* **const** &*lower_id*, *std*::uint64_t *count*, *naming*::*address* **const** &*baseaddr*, *std*::uint64_t *offset*, *std*::uint32_t *locality_id*)

bool **unbind_local**(*naming*::*gid_type* **const** &*id*, *error_code* &*ec* = *throws*)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

Return The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

Note You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind_range*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will raise an error if the global reference count of the given gid is not zero! TODO: confirm that this happens.

Parameters

- `id`: [in] The global address (id) for which the association has to be removed.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **unbind_local**(*naming*::*gid_type* **const** &*id*, *naming*::*address* &*addr*, *error_code* &*ec* = *throws*)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

Return The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

Note You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind_range*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will raise an error if the global reference count of the given gid is not zero! TODO: confirm that this happens.

Parameters

- `id`: [in] The global address (id) for which the association has to be removed.
- `addr`: [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`unbind_range_local`**(*naming*::*gid_type* **const** &*lower_id*, *std*::uint64_t *count*, *error_code* &*ec* = *throws*)

Unbind the given range of global ids.

Return This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

Note You can unbind only global ids bound using the function *bind_range*. Do not use this function to unbind any of the global ids bound using *bind*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will raise an error if the global reference count of the given gid is not zero! TODO: confirm that this happens.

Parameters

- `lower_id`: [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to *bind_range*.
- `count`: [in] The number of consecutive global ids to unbind starting at *lower_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind_range*
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`unbind_range_local`**(*naming*::*gid_type* **const** &*lower_id*, *std*::uint64_t *count*, *naming*::*address* &*addr*, *error_code* &*ec* = *throws*)

Unbind the given range of global ids.

Return This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call.

Note You can unbind only global ids bound using the function *bind_range*. Do not use this function to unbind any of the global ids bound using *bind*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- `lower_id`: [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to *bind_range*.
- `count`: [in] The number of consecutive global ids to unbind starting at *lower_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind_range*
- `addr`: [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<*naming*::*address*> **`unbind_range_async`**(*naming*::*gid_type* **const** &*lower_id*, *std*::uint64_t *count* = 1)

bool **`is_local_address_cached`**(*naming*::*gid_type* **const** &*id*, *error_code* &*ec* = *throws*)

Test whether the given address refers to a local object.

This function will test whether the given address refers to an object living on the locality of the caller.

Return This function returns *true* if the passed address refers to an object which lives on the locality of the caller.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `addr`: [in] The address to test.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`is_local_address_cached`**(*naming*::*gid_type* **const** &*id*, *naming*::*address* &*addr*, *error_code* &*ec* = *throws*)

bool **`is_local_lva_encoded_address`**(*std*::uint64_t *msb*)

bool **`resolve_local`**(*naming*::*gid_type* **const** &*id*, *naming*::*address* &*addr*, *error_code* &*ec* = *throws*)

Resolve a given global address (*id*) to its associated local address.

This function returns the local address which is currently associated with the given global address (*id*).

Return This function returns *true* if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The function returns *false* if no association exists for the given global address. Any error results in an exception thrown from this function.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The global address (*id*) for which the associated local address should be returned.
- `addr`: [out] The local address which currently is associated with the given global address (id), this is valid only if the return value of this function is true.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

bool **`resolve_local`**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &*addr*, *error_code* &*ec* = *throws*)

bool **resolve_full_local**(*naming*::*gid_type* **const** **gids*, *naming*::*address* **addrs*, *std*::size_t *size*, *boost*::dynamic_bitset<> &*locals*, *error_code* &*ec* = *throws*)

bool **resolve_cached**(*naming*::*gid_type* **const** **gids*, *naming*::*address* **addrs*, *std*::size_t *size*, *boost*::dynamic_bitset<> &*locals*, *error_code* &*ec* = *throws*)

hpx::future<*std*::int64_t> **incref_async**(*naming*::*gid_type* **const** &*gid*, *std*::int64_t *credits* = 1, *hpx*::*id_type* **const** &*keep_alive* = *hpx*::*invalid_id*)

Increment the global reference count for the given id.

Return Whether the operation was successful.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The global address (id) for which the global reference count has to be incremented.
- `credits`: [in] The number of reference counts to add for the given id.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::int64_t **incref**(*naming*::*gid_type* **const** &*gid*, *std*::int64_t *credits* = 1, *error_code* &*ec* = *throws*)

void **decref**(*naming*::*gid_type* **const** &*id*, *std*::int64_t *credits* = 1, *error_code* &*ec* = *throws*)

Decrement the global reference count for the given id.

Return The global reference count after the decrement.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `id`: [in] The global address (id) for which the global reference count has to be decremented.
- `t`: [out] If this was the last outstanding global reference for the given gid (the return value of this function is zero), t will be set to the component type of the corresponding element. Otherwise t will not be modified.
- `credits`: [in] The number of reference counts to add for the given id.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<*iterate_names_return_type*> **iterate_ids**(*std*::string **const** &*pattern*)

Invoke the supplied *hpx::function* for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

Parameters
- `pattern`: [in] pattern (poosibly using wildcards) to match all existing entries against

bool **register_name**(*std*::string **const** &*name*, *naming*::*gid_type* **const** &*id*, *error_code* &*ec* = *throws*)

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

Return The function returns *true* if the global name was registered. It returns false if the global name is not registered.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters
- `name`: [in] The global name (string) to be associated with the global address.
- `id`: [in] The global address (id) to be associated with the global address.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<bool> **register_name_async**(*std*::string **const** &*name*, *hpx*::*id_type* **const** &*id*)

bool **register_name**(*std*::string **const** &*name*, *hpx*::*id_type* **const** &*id*, *error_code* &*ec* = *throws*)

hpx::future<*hpx*::*id_type*> **unregister_name_async**(*std*::string **const** &*name*)

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

Return The function returns *true* if an association of this global name has been released, and it returns *false*, if no association existed. Any error results in an exception thrown from this function.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters
- `name`: [in] The global name (string) for which any association with a global address (id) has to be released.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*id_type* **unregister_name**(*std*::string **const** &*name*, *error_code* &*ec* = *throws*)

hpx::future<*hpx*::*id_type*> **resolve_name_async**(*std*::string **const** &*name*)

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

This function returns true if it returned global address (id), which is currently associated with the given global name, and it returns false, if currently there is no association for this global name. Any error results in an exception thrown from this function.

Return [out] The id currently associated with the given global name (valid only if the return value is true).

Parameters

- `name`: [in] The global name (string) for which the currently associated global address has to be retrieved.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

hpx::*id_type* **resolve_name**(*std*::string **const** &*name*, *error_code* &*ec* = *throws*)

future<*hpx*::*id_type*> **on_symbol_namespace_event**(*std*::string **const** &*name*, bool *call_for_past_events* = false)

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.

Return A future instance encapsulating the global id which is causing the registered listener to be triggered.

Note The only event type which is currently supported is *symbol_ns_bind*, i.e. the listener is triggered whenever a global id is registered with the given name.

Parameters

- `name`: [in] The global name (string) for which the given event should be triggered.
- `evt`: [in] The event for which a listener should be installed.
- `call_for_past_events`: [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is *false*.

void **update_cache_entry**(*naming*::*gid_type* **const** &*gid*, *gva* **const** &*gva*, *error_code* &*ec* = *throws*)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void **update_cache_entry**(*naming*::*gid_type* **const** &*gid*, *naming*::*address* **const** &*addr*, *std*::uint64_t *count* = 0, *std*::uint64_t *offset* = 0, *error_code* &*ec* = *throws*)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

bool **get_cache_entry**(*naming*::*gid_type* **const** &*gid*, *gva* &*gva*, *naming*::*gid_type* &*idbase*, *error_code* &*ec* = *throws*)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void **remove_cache_entry**(*naming*::*gid_type* **const** &*id*, *error_code* &*ec* = *throws*)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void **clear_cache**(*error_code* &*ec* = *throws*)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void **start_shutdown**(*error_code* &*ec* = *throws*)

hpx::future<*std*::pair<*hpx*::*id_type*, *naming*::*address*>> **begin_migration**(*hpx*::*id_type* **const** &*id*)

start/stop migration of an object

Return Current locality and address of the object to migrate

bool **end_migration**(*hpx*::*id_type* **const** &*id*)

std::pair<bool, *components*::*pinned_ptr*> **was_object_migrated**(*naming*::*gid_type* **const** &*gid*, *hpx*::move_only_function<*components*::*pinned*

> &&*f*Maintain list of migrated objects.

hpx::future<void> **mark_as_migrated**(*naming*::*gid_type* **const** &*gid*, *hpx*::move_only_function<*std*::pair<bool, *hpx*::future<void>>)

> &&*f*bool *expect_to_be_marked_as_migrating*Mark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

void **unmark_as_migrated**(*naming*::*gid_type* **const** &*gid*)

Remove the given object from the table of migrated objects.

void **pre_cache_endpoints**(*std*::vector<*parcelset*::*endpoints_type*> **const**&)

namespace server

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

```
|-----MSB------||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|

MSB        - Most significant bits (bit 64 to bit 127)
LSB        - Least significant bits (bit 0 to bit 63)
prefix     - Highest 32 bits (bit 96 to bit 127) of the MSB. Each
             locality is assigned a prefix. This creates a 96-bit
             address space for each locality.
RC         - Bit 88 to bit 92 of the MSB. This is the log2 of the number
             of reference counting credits on the GID.
             Bit 93 is used by the locking scheme for gid_types.
             Bit 94 is a flag which is set if the credit value is valid.
             Bit 95 is a flag that is set if a GID's credit count is
             ever split (e.g. if the GID is ever passed to another
             locality).
           - Bit 87 marks the gid such that it will not be stored in
             any of the AGAS caches. This is used mainly for ids
             which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The
             content of these bits depends on the component type of
             the underlying object. For all user-defined components,
             these bits contain a unique 88-bit number which is
             assigned sequentially for each locality. For
             \a hpx#components#component_runtime_support the high 24
             bits are zeroed and the low 64 bits hold the LVA of the
             component.
```

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
00000001000000010000000000000001
    Address of the primary_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000002
    Address of the component_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000003
    Address of the symbol_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000004
    Address of the locality_namespace component on the bootstrap AGAS
    locality.
```

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

```
|-----MSB------||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|

MSB        - Most significant bits (bit 64 to bit 127)
LSB        - Least significant bits (bit 0 to bit 63)
prefix     - Highest 32 bits (bit 96 to bit 127) of the MSB. Each
             locality is assigned a prefix. This creates a 96-bit
             address space for each locality.
RC         - Bit 88 to bit 92 of the MSB. This is the log2 of the number
             of reference counting credits on the GID.
             Bit 93 is used by the locking scheme for gid_types.
             Bit 94 is a flag which is set if the credit value is valid.
             Bit 95 is a flag that is set if a GID's credit count is
             ever split (e.g. if the GID is ever passed to another
             locality).
           - Bit 87 marks the gid such that it will not be stored in
             any of the AGAS caches. This is used mainly for ids
             which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The
             content of these bits depends on the component type of
             the underlying object. For all user-defined components,
             these bits contain a unique 88-bit number which is
             assigned sequentially for each locality. For
             \a hpx#components#component_runtime_support the high 24
             bits are zeroed and the low 64 bits hold the LVA of the
             component.
```

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
00000001000000010000000000000001
    Address of the primary_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000002
    Address of the component_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000003
    Address of the symbol_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000004
    Address of the locality_namespace component on the bootstrap AGAS
    locality.
```

namespace server

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

```
|-----MSB------||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|

MSB        - Most significant bits (bit 64 to bit 127)
LSB        - Least significant bits (bit 0 to bit 63)
prefix     - Highest 32 bits (bit 96 to bit 127) of the MSB. Each
             locality is assigned a prefix. This creates a 96-bit
             address space for each locality.
RC         - Bit 88 to bit 92 of the MSB. This is the log2 of the number
             of reference counting credits on the GID.
             Bit 93 is used by the locking scheme for gid_types.
             Bit 94 is a flag which is set if the credit value is valid.
             Bit 95 is a flag that is set if a GID's credit count is
             ever split (e.g. if the GID is ever passed to another
             locality).
           - Bit 87 marks the gid such that it will not be stored in
             any of the AGAS caches. This is used mainly for ids
             which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The
             content of these bits depends on the component type of
             the underlying object. For all user-defined components,
             these bits contain a unique 88-bit number which is
             assigned sequentially for each locality. For
             \a hpx#components#component_runtime_support the high 24
             bits are zeroed and the low 64 bits hold the LVA of the
             component.
```

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
00000001000000010000000000000001
    Address of the primary_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000002
```

(continues on next page)

(continued from previous page)

```
    Address of the component_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000003
    Address of the symbol_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000004
    Address of the locality_namespace component on the bootstrap AGAS

namespace hpx

Functions

hpx::*id_type* **get_colocation_id**(*launch*::sync_policy, *hpx*::*id_type* **const** &*id*, *error_code* &*ec* = *throws*)

Return the id of the locality where the object referenced by the given id is currently located on.

The function *hpx::get_colocation_id()* returns the id of the locality where the given object is currently located.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

See hpx::get_colocation_id()

Parameters

- `id`: [in] The id of the object to locate.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::future<*hpx*::*id_type*> **get_colocation_id**(*hpx*::*id_type* **const** &*id*)

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

See *hpx::get_colocation_id(launch::sync_policy)*

Parameters

- `id`: [in] The id of the object to locate.

namespace lcos

class base_lco

#include <base_lco.hpp> The base_lco class is the common base class for all LCO's implementing a simple set_event action

Subclassed by *hpx::lcos::base_lco_with_value< Result, RemoteResult, ComponentTag >*, *hpx::lcos::base_lco_with_value< void, void, ComponentTag >*

Public Types

typedef *components::managed_component<base_lco>* **wrapping_type**

typedef *base_lco* **base_type_holder**

Public Functions

virtual void **set_event**() = 0

virtual void **set_exception**(*std*::exception_ptr **const** &*e*)

virtual void **connect**(*hpx*::*id_type* **const**&)

virtual void **disconnect**(*hpx*::*id_type* **const**&)

virtual ~base_lco()
Destructor, needs to be virtual to allow for clean destruction of derived objects

virtual void **finalize**()
finalize() will be called just before the instance gets destructed

void **set_event_nonvirt**()
The *function* set_event_nonvirt is called whenever a *set_event_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set_event*, which is overloaded by the derived concrete LCO.

void **set_exception_nonvirt**(*std*::exception_ptr **const** &*e*)
The *function* set_exception is called whenever a *set_exception_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set_exception*, which is overloaded by the derived concrete LCO.

Parameters
- `e`: [in] The exception encapsulating the error to report to this LCO instance.

void **connect_nonvirt**(*hpx*::*id_type* **const** &*id*)
The *function* connect_nonvirt is called whenever a *connect_action* is applied on a instance of a LCO. This function just forwards to the virtual function *connect*, which is overloaded by the derived concrete LCO.

Parameters
- `id`: [in] target id

void **disconnect_nonvirt**(*hpx*::*id_type* **const** &*id*)
The *function* disconnect_nonvirt is called whenever a *disconnect_action* is applied on a instance of a LCO. This function just forwards to the virtual function *disconnect*, which is overloaded by the derived concrete LCO.

Parameters
- `id`: [in] target id

HPX_DEFINE_COMPONENT_DIRECT_ACTION(*base_lco*, *set_event_nonvirt*, set_event_action)
Each of the exposed functions needs to be encapsulated into an action type, allowing to generate all required boilerplate code for threads, serialization, etc.

The *set_event_action* may be used to unconditionally trigger any LCO instances, it carries no additional parameters. The *set_exception_action* may be used to transfer arbitrary error information from the remote site to the LCO instance specified as a continuation. This action carries 2 parameters:

Parameters

- `std::exception_ptr`: [in] The exception encapsulating the error to report to this LCO instance.

set_exception_action **HPX_DEFINE_COMPONENT_DIRECT_ACTION**(*base_lco*, *connect_nonvirt*, connect_action)

The *connect_action* may be used to.

The *set_exception_action* may be used to

namespace hpx

namespace lcos

template<typename **Result**, typename **RemoteResult**, typename **ComponentTag**>
class base_lco_with_value : **public** *hpx::lcos::base_lco*, **public** *ComponentTag*

#include <base_lco_with_value.hpp> The base_lco_with_value class is the common base class for all LCO's synchronizing on a value. The *RemoteResult* template argument should be set to the type of the argument expected for the set_value action.

Template Parameters

- `RemoteResult`: The type of the result value to be carried back to the LCO instance.
- `ComponentTag`: The tag type representing the type of the component (either component_tag or managed_component_tag).

Public Types

template<>
using wrapping_type = **typename** detail::base_lco_wrapping_type<ComponentTag, base_lco_with_value>::ty

template<>
using base_type_holder = base_lco_with_value

Public Functions

void **set_value_nonvirt**(RemoteResult &&*result*)

The *function* set_value_nonvirt is called whenever a *set_value_action* is applied on this LCO instance. This function just forwards to the virtual function *set_value*, which is overloaded by the derived concrete LCO.

Parameters

- `result`: [in] The result value to be transferred from the remote operation back to this LCO instance.

Result **get_value_nonvirt**()

The *function* get_result_nonvirt is called whenever a *get_result_action* is applied on this LCO instance. This function just forwards to the virtual function *get_result*, which is overloaded by the derived concrete LCO.

HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco_with_value, *set_value_nonvirt*, set_value_action)

The *set_value_action* may be used to trigger any LCO instances while carrying an additional parameter of any type.

RemoteResult is taken by rvalue ref. This allows for perfect forwarding. When the action thread function is created, the values are moved into the called function. If we took it by const lvalue reference, we would disable the possibility to further move the result to the designated destination.

Parameters

- `RemoteResult`: [in] The type of the result to be transferred back to this LCO instance. The *get_value_action* may be used to query the value this LCO instance exposes as its 'result' value.

namespace hpx

namespace distributed

template<typename **Result**, typename **RemoteResult**>
class promise

#include <promise.hpp> A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO's set_event action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)
hpx::distributed::promise<hpx::id_type> p;

// Get the associated future
future<hpx::id_type> f = p.get_future();

// initiate the action supplying the promise as a
// continuation
apply<some_action>(new continuation(p.get_id()), ...);

// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

Note The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

Template Parameters

- `Result`: The template parameter *Result* defines the type this promise is expected to return from *promise::get*.

- `RemoteResult`: The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

namespace lcos

Typedefs

using instead = *hpx*::*distributed*::*promise*<Result, RemoteResult>

template<typename **Action**, typename **Result** = **typename** *traits*::*promise_local_result*<**typename** *Action*::remote_r
class packaged_action

#include <packaged_action.hpp> A *packaged_action* can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the *packaged_action* using the LCO's set_event action

A *packaged_action* is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*.

Note The action executed using the *packaged_action* as a continuation must return a value of a type convertible to the type as specified by the template parameter *Result*.

Template Parameters

- `Action`: The template parameter *Action* defines the action to be executed by this *packaged_action* instance. The arguments *arg0,... argN* are used as parameters for this action.
- `Result`: The template parameter *Result* defines the type this *packaged_action* is expected to return from its associated future *packaged_action::get_future*.
- `DirectExecute`: The template parameter *DirectExecute* is an optimization aid allowing to execute the action directly if the target is local (without spawning a new thread for this). This template does not have to be supplied explicitly as it is derived from the template parameter *Action*.

template<>
class promise<void, *hpx*::*util*::*unused_type*> : **public** *lcos*::detail::promise_base<void, *hpx*::*util*::*unused_type*, *lcos*::detail::prom

Public Functions

promise()
constructs a promise object and a shared state.

template<typename **Allocator**>
promise(*std*::allocator_arg_t, *Allocator* **const** &*a*)
constructs a promise object and a shared state. The constructor uses the allocator a to allocate the memory for the shared state.

promise(*promise* &&*other*)
constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly-constructed object.

Post other has no shared state.

~promise()
Abandons any shared state.

promise &**operator=**(promise &&*other*)
Abandons any shared state (30.6.4) and then as if promise(HPX_MOVE(other)).swap(*this).

Return *this.

void **swap**(promise &*other*)
Exchanges the shared state of *this and other.

Post *this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

void **set_value**()
atomically stores the value r in the shared state and makes that state ready (30.6.4).

Exceptions

- `future_error`: if its shared state already has a stored value. if shared state has no stored value exception is raised. promise_already_satisfied if its shared state already has a stored value or exception. no_state if *this has no shared state.

Functions

void **trigger_lco_event**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, bool *move_credits* = true)
Trigger the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should be triggered.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **trigger_lco_event**(*hpx*::*id_type* **const** &*id*, bool *move_credits* = true)
Trigger the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should be triggered.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **trigger_lco_event**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *hpx*::*id_type* **const** &*cont*, bool *move_credits* = true)
Trigger the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should be triggered.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **trigger_lco_event**(*hpx*::*id_type* **const** &*id*, *hpx*::*id_type* **const** &*cont*, bool *move_credits* = true)
Trigger the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should be triggered.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
void **set_lco_value**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *Result* &&*t*, bool *move_credits* = true)

Set the result value for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the given value.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `t`: [in] This is the value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
std::enable_if<!*std*::is_same<**typename** *std*::decay<*Result*>::type, *naming*::*address*>::value>::type **set_lco_value**(*hpx*::*id_* **const** &*id*, *Result* &&*t*, bool *move_c* = true)

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the given value.
- `t`: [in] This is the value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
std::enable_if<!*std*::is_same<**typename** *std*::decay<*Result*>::type, *naming*::*address*>::value>::type **set_lco_value_unman**

Set the result value for the (unmanaged) LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the given value.
- `t`: [in] This is the value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
void **set_lco_value**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *Result* &&*t*, *hpx*::*id_type* **const** &*cont*, bool *move_credits* = true)

Set the result value for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the given value.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `t`: [in] This is the value which should be sent to the LCO.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
std::enable_if<!*std*::is_same<**typename** *std*::decay<*Result*>::type, *naming*::*address*>::value>::type **set_lco_value**(*hpx*::*id_* **const** &*id*, *Result* &&*t*, *hpx*::*id_* **const** &*cont*, bool *move_c* = true)

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the given value.
- `t`: [in] This is the value which should be sent to the LCO.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

std::enable_if<!*std*::is_same<**typename** *std*::decay<*Result*>::type, *naming*::*address*>::value>::type **set_lco_value_unman**

Set the result value for the (unmanaged) LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the given value.
- `t`: [in] This is the value which should be sent to the LCO.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set_lco_error**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *std*::exception_ptr **const** &*e*, bool *move_credits* = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `e`: [in] This is the error value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set_lco_error**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *std*::exception_ptr &&*e*, bool *move_credits* = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `e`: [in] This is the error value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set_lco_error**(*hpx*::*id_type* **const** &*id*, *std*::exception_ptr **const** &*e*, bool *move_credits* = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `e`: [in] This is the error value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* **const** &*id*, *std*::exception_ptr &&*e*, bool *move_credits* = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `e`: [in] This is the error value which should be sent to the LCO.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *std*::exception_ptr **const** &*e*, *hpx*::*id_type* **const** &*cont*, bool *move_credits* = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `e`: [in] This is the error value which should be sent to the LCO.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* **const** &*id*, *naming*::*address* &&*addr*, *std*::exception_ptr &&*e*, *hpx*::*id_type* **const** &*cont*, bool *move_credits* = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `addr`: [in] This represents the addr of the LCO which should be triggered.
- `e`: [in] This is the error value which should be sent to the LCO.

checkpoint

See *Public API* for a list of names and headers that are part of the public *HPX* API.

This header defines the save_checkpoint and restore_checkpoint functions. These functions are designed to help HPX application developer's checkpoint their applications. Save_checkpoint serializes one or more objects and saves them as a byte stream. Restore_checkpoint converts the byte stream back into instances of the objects.

namespace hpx

namespace util

Functions

std::ostream &**operator<<** (*std*::ostream &*ost*, *checkpoint* **const** &*ckp*)
Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters

- `ost`: Output stream to write to.
- `ckp`: Checkpoint to copy from.

Return Operator<< returns the ostream object.

std::istream &**operator>>** (*std*::istream &*ist*, *checkpoint* &*ckp*)
Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

Parameters

- `ist`: Input stream to write from.
- `ckp`: Checkpoint to write to.

Return Operator>> returns the ostream object.

template<typename **T**, typename ...**Ts**, typename **U** = **typename** *std*::enable_if<!*hpx*::*traits*::is_launch_policy<*T*>::value &
hpx::future<*checkpoint*> **save_checkpoint** (*T &&t*, *Ts&&... ts*)

Save_checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `U`: This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

Parameters

- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>
hpx::future<*checkpoint*> **save_checkpoint** (*checkpoint &&c*, *T &&t*, *Ts&&... ts*)

Save_checkpoint - Take a pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- `c`: Takes a pre-initialized checkpoint to copy data into.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**, typename **U** = **typename** *std*::enable_if<!*std*::is_same<**typename** *std*::decay<*T*>
hpx::future<*checkpoint*> **save_checkpoint** (*hpx*::*launch p*, *T* &&*t*, *Ts*&&... *ts*)

Save_checkpoint - Policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- `p`: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>
hpx::future<*checkpoint*> **save_checkpoint** (*hpx*::*launch p*, *checkpoint* &&*c*, *T* &&*t*, *Ts*&&... *ts*)

Save_checkpoint - Policy overload & pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- `p`: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- `c`: Takes a pre-initialized checkpoint to copy data into.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass

hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**, typename **U** = **typename** *std*::enable_if<!*std*::is_same<**typename** *std*::decay<*T*>
checkpoint **save_checkpoint** (*hpx*::*launch*::sync_policy *sync_p*, *T* &&*t*, *Ts*&&... *ts*)

Save_checkpoint - Sync_policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `U`: This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

Parameters

- `sync_p`: hpx::launch::sync_policy
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename **T**, typename ...**Ts**>
checkpoint **save_checkpoint** (*hpx*::*launch*::sync_policy *sync_p*, *checkpoint* &&*c*, *T* &&*t*, *Ts*&&... *ts*)

Save_checkpoint - Sync_policy overload & pre-init. checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- `sync_p`: hpx::launch::sync_policy
- `c`: Takes a pre-initialized checkpoint to copy data into.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename **T**, typename ...**Ts**, typename **U** = **typename** *std*::enable_if<!*hpx*::*traits*::is_launch_policy<*T*>::value &

hpx::future<*checkpoint*> **prepare_checkpoint** (*T* **const** &*t*, *Ts* **const**&... *ts*)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Return prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

Template Parameters

- `T`: A container to restore.
- `Ts`: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

template<typename **T**, typename ...**Ts**>
hpx::future<*checkpoint*> **prepare_checkpoint** (*checkpoint* &&*c*, *T* **const** &*t*, *Ts* **const**&... *ts*)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Return prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

Template Parameters

- `T`: A container to restore.
- `Ts`: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- `c`: Takes a pre-initialized checkpoint to prepare
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

template<typename **T**, typename ...**Ts**, typename **U** = **typename** *std*::enable_if<!*std*::is_same<*T*, *checkpoint*>::value>::typ

- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

template<typename **T**, typename ...**Ts**>
void **restore_checkpoint** (*checkpoint* **const** &*c*, *T* &*t*, *Ts*&... *ts*)

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in a instance of a component's shared_ptr or by passing in an instance of the component's client.

Return Restore_checkpoint returns void.

Template Parameters

- `T`: A container to restore.
- `Ts`: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- `c`: The checkpoint to restore.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

class checkpoint

#include <*checkpoint.hpp*> Checkpoint Object

Checkpoint is the container object which is produced by save_checkpoint and is consumed by a restore_checkpoint. A checkpoint may be moved into the save_checkpoint object to write the byte stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are able to be serialized including components.

Restore_checkpoint can resurrect a stored component in two ways: by passing in a instance of a component's shared_ptr or by passing in an instance of the component's client.

Return Restore_checkpoint returns void.

Template Parameters

- `T`: A container to restore.
- `Ts`: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- `c`: The checkpoint to restore.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

bool **operator==** (checkpoint **const** &*lhs*, checkpoint **const** &*rhs*)

bool **operator!=** (checkpoint **const** &*lhs*, checkpoint **const** &*rhs*)

checkpoint_base

namespace hpx

namespace util

Functions

template<typename **Container**, typename ...**Ts**>
void **save_checkpoint_data**(*Container &data*, *Ts&&... ts*)
save_checkpoint_data

Save_checkpoint_data takes any number of objects which a user may wish to store in the given container.

Template Parameters
- `Container`: Container used to store the check-pointed data.
- `Ts`: Types of variables to checkpoint

Parameters
- `cont`: Container instance used to store the checkpoint data
- `ts`: Variable instances to be inserted into the checkpoint.

template<typename ...**Ts**>
std::size_t **prepare_checkpoint_data**(*Ts* **const**&... *ts*)
prepare_checkpoint_data

prepare_checkpoint_data takes any number of objects which a user may wish to store in a subsequent save_checkpoint_data operation. The function will return the number of bytes necessary to store the data that will be produced.

Template Parameters
- `Ts`: Types of variables to checkpoint

Parameters
- `ts`: Variable instances to be inserted into the checkpoint.

template<typename **Container**, typename ...**Ts**>
void **restore_checkpoint_data**(*Container* **const** *&cont*, *Ts&... ts*)
restore_checkpoint_data

restore_checkpoint_data takes any number of objects which a user may wish to restore from the given container. The sequence of objects has to correspond to the sequence of objects for the corresponding call to save_checkpoint_data that had used the given container instance.

Template Parameters
- `Container`: Container used to restore the check-pointed data.
- `Ts`: Types of variables to restore

Parameters
- `cont`: Container instance used to restore the checkpoint data
- `ts`: Variable instances to be restored from the container

namespace hpx

namespace collectives

Functions

template<typename **T**>
hpx::future<*std*::vector<*std*::decay_t<*T*>>> **all_gather**(char **const** **basename*, *T &&result*, *num_sites_arg num_sites = num_sites_arg*(), *this_site_arg this_site = this_site_arg*(), *generation_arg generation = generation_arg*(), *root_site_arg root_site = root_site_arg*())

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_gather operation has been completed.

Parameters

- `basename`: The base name identifying the all_gather operation
- `local_result`: The value to transmit to all participating sites from this call site.
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the all_gather operation performed on the given base name. This is optional and needs to be supplied only if the all_gather operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. \params root_site The site that is responsible for creating the all_gather support object. This value is optional and defaults to '0' (zero).

template<typename **T**>
hpx::future<*std*::vector<*std*::decay_t<*T*>>> **all_gather**(communicator *comm*, *T &&result*, *this_site_arg this_site = this_site_arg*())

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_gather operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_reducer*
- `local_result`: The value to transmit to all participating sites from this call site.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace distributed

class barrier

#include <barrier.hpp> The barrier is an implementation performing a barrier over a number of participating threads. The different threads don't have to be on the same locality. This barrier can be invoked in a distributed application.

For a local only barrier
See hpx::barrier.

Public Functions

barrier(*std*::string **const** &*base_name*)
Creates a barrier, rank is locality id, size is number of localities

A barrier *base_name* is created. It expects that hpx::get_num_localities() participate and the local rank is hpx::get_locality_id().
Parameters
- `base_name`: The name of the barrier

barrier(*std*::string **const** &*base_name*, *std*::size_t *num*)
Creates a barrier with a given size, rank is locality id

A barrier *base_name* is created. It expects that *num* participate and the local rank is hpx::get_locality_id().
Parameters
- `base_name`: The name of the barrier
- `num`: The number of participating threads

barrier(*std*::string **const** &*base_name*, *std*::size_t *num*, *std*::size_t *rank*)
Creates a barrier with a given size and rank

A barrier *base_name* is created. It expects that *num* participate and the local rank is *rank*.
Parameters
- `base_name`: The name of the barrier
- `num`: The number of participating threads
- `rank`: The rank of the calling site for this invocation

barrier(*std*::string **const** &*base_name*, *std*::vector<*std*::size_t> **const** &*ranks*, *std*::size_t *rank*)
Creates a barrier with a vector of ranks

A barrier *base_name* is created. It expects that ranks.size() and the local rank is *rank* (must be contained in *ranks*).
Parameters
- `base_name`: The name of the barrier
- `ranks`: Gives a list of participating ranks (this could be derived from a list of locality ids
- `rank`: The rank of the calling site for this invocation

void **wait**()
Wait until each participant entered the barrier. Must be called by all participants

Return This function returns once all participants have entered the barrier (have called *wait*).

hpx::future<void> **wait**(*hpx*::*launch*::async_policy)
Wait until each participant entered the barrier. Must be called by all participants

Return a future that becomes ready once all participants have entered the barrier (have called *wait*).

Public Static Functions

static void **synchronize**()

Perform a global synchronization using the default global barrier The barrier is created once at startup and can be reused throughout the lifetime of an HPX application.

Note This function currently does not support dynamic connection and disconnection of localities.

namespace hpx

namespace collectives

Functions

template<typename **T**>
hpx::future<void> **broadcast_to**(char **const** **basename*, *T &&local_result*, *num_sites_arg num_sites = num_sites_arg*(), *this_site_arg this_site = this_site_arg*(), *generation_arg generation = generation_arg*())

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

Return This function returns a future that will become ready once the broadcast operation has been completed.

Parameters

- `basename`: The base name identifying the broadcast operation
- `local_result`: A value to transmit to all participating sites from this call site.
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**>
hpx::future<void> **broadcast_to**(communicator *comm*, *T &&local_result*, *this_site_arg this_site = this_site_arg*())

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

Return This function returns a future that will become ready once the broadcast operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_reducer*
- `local_result`: A value to transmit to all participating sites from this call site.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**>

hpx::future<*T*> **broadcast_from**(char **const** **basename*, *this_site_arg this_site* = *this_site_arg*(), *generation_arg generation* = *generation_arg*())

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

Return This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

Parameters

- `basename`: The base name identifying the broadcast operation
- `generation`: The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**>
hpx::future<*T*> **broadcast_from**(communicator *comm*, *this_site_arg this_site* = *this_site_arg*())

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

Return This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_reducer*
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace lcos

Functions

template<typename Action, typename ArgN, ...>hpx::future<std::vector<decltype(Actio

Perform a distributed broadcast operation.

The function hpx::lcos::broadcast performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

Return This function returns a future representing the result of the overall reduction operation.

Note If decltype(Action(...)) is void, then the result of this function is future<void>.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

template<typename Action, typename ArgN, ...>void hpx::lcos::broadcast_apply(std::v

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function hpx::lcos::broadcast_apply performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

template<typename Action, typename ArgN, ...>hpx::future< std::vector<decltype(Acti

Perform a distributed broadcast operation.

The function hpx::lcos::broadcast_with_index performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Return This function returns a future representing the result of the overall reduction operation.
Note If decltype(Action(...)) is void, then the result of this function is future<void>.
Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

template<typename Action, typename ArgN, ...>void hpx::lcos::broadcast_apply_with_i

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function hpx::lcos::broadcast_apply_with_index performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

namespace hpx

namespace collectives

Functions

hpx::future<channel_communicator> **create_channel_communicator**(char **const** **basename*, *num_sites_arg num_sites* = *num_sites_arg*(), *this_site_arg this_site* = *this_site_arg*())

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

Return This function returns a future to a new communicator object usable with the collective operation.

Parameters

- `basename`: The base name identifying the collective operation
- `num_sites`: The number of participating sites (default: all localities).
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

channel_communicator **create_channel_communicator**(*hpx*::*launch*::sync_policy, char **const** **basename*, *num_sites_arg num_sites* = *num_sites_arg*(), *this_site_arg this_site* = *this_site_arg*())

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

Return This function returns a new communicator object usable with the collective operation.

Parameters

- `basename`: The base name identifying the collective operation
- `num_sites`: The number of participating sites (default: all localities).
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**>
hpx::future<void> **set**(channel_communicator *comm*, *that_site_arg site*, *T &&value*, *tag_arg tag* = 0)

Send a value to the given site

This function sends a value to the given site based on the given communicator.

Return This function returns a future<void> that becomes ready once the data transfer operation has finished.

Parameters

- `comm`: The channel communicator object to use for the data transfer
- `site`: The destination site
- `value`: The value to send
- `tag`: The (optional) tag identifying the concrete operation

template<typename **T**>
hpx::future<*T*> **get** (channel_communicator *comm*, *that_site_arg site*, *tag_arg tag* = 0)

Send a value to the given site

This function receives a value from the given site based on the given communicator.

Return This function returns a future<T> that becomes ready once the data transfer operation has finished. The future will hold the received value.

Parameters

- `comm`: The channel communicator object to use for the data transfer
- `site`: The source site

namespace hpx

namespace lcos

Functions

hpx::future<*hpx*::*id_type*> **create_communication_set** (char **const** **basename*, *std*::size_t *num_sites* = *std*::size_t(-1), *std*::size_t *this_site* = *std*::size_t(-1), *std*::size_t *arity* = *std*::size_t(-1))

The function *create_communication_set* sets up a (distributed) tree-like communication structure that can be used with any of the collective APIs (such like *all_to_all* and similar).

Return This function returns a future holding an id_type of the communicator object to be used on the current locality.

Parameters

- `basename`: The base name identifying the all_to_all operation
- `num_sites`: The number of participating sites (default: all localities).
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- `arity`: The number of children each of the communication nodes is connected to (default: picked based on num_sites)

namespace hpx

namespace collectives

Functions

communicator **create_communicator**(char **const** *basename, *num_sites_arg num_sites = num_sites_arg(), *this_site_arg this_site = this_site_arg(), *generation_arg generation = generation_arg(), *root_site_arg root_site = root_site_arg())

Create a new communicator object usable with any collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of any of the collective operations (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

Return This function returns a new communicator object usable with the collective operation.

Parameters

- `basename`: The base name identifying the collective operation
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. \params root_site The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

namespace hpx

namespace collectives

Functions

template<typename **T**, typename **F**>
hpx::future<*std*::decay_t<*T*>> **exclusive_scan**(char **const** *basename, *T* &&*result*, *F* &&*op*, *num_sites_arg num_sites = num_sites_arg(), *this_site_arg this_site = this_site_arg(), *generation_arg generation = generation_arg(), *root_site_arg root_site = root_site_arg())

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Note The result returned on the root_site is always the same as the result returned on thus_site == 1 and is the same as the value provided by the thje root_site.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive_scan operation has been completed.

Parameters

- `basename`: The base name identifying the exclusive_scan operation
- `local_result`: The value to transmit to all participating sites from this call site.
- `op`: Reduction operation to apply to all values supplied from all participating sites
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be sup-

plied only if the exclusive_scan operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. \params root_site The site that is responsible for creating the exclusive_scan support object. This value is optional and defaults to '0' (zero).

template<typename **T**, typename **F**>
hpx::future<*std*::decay_t<*T*>> **exclusive_scan**(communicator *comm*, *T &&result*, *F &&op*, *this_site_arg this_site* = *this_site_arg*())

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Note The result returned on the root_site is always the same as the result returned on thus_site == 1 and is the same as the value provided by the thje root_site.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive_scan operation has been completed.

Parameters
- `comm`: A communicator object returned from *create_reducer*
- `local_result`: The value to transmit to all participating sites from this call site.
- `op`: Reduction operation to apply to all values supplied from all participating sites
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace lcos

Functions

template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>hpx::f

Perform a distributed fold operation.

The function hpx::lcos::fold performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

Note The type of the initial value must be convertible to the result type returned from the invoked action.

Return This function returns a future representing the result of the overall folding operation.

Parameters
- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- `init`: [in] The initial value to be used for the folding operation
- `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>hpx::f

Perform a distributed folding operation.

The function hpx::lcos::fold_with_index performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Note The type of the initial value must be convertible to the result type returned from the invoked action.

Return This function returns a future representing the result of the overall folding operation.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- `init`: [in] The initial value to be used for the folding operation
- `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>hpx::f

Perform a distributed inverse folding operation.

The function hpx::lcos::inverse_fold performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

Note The type of the initial value must be convertible to the result type returned from the invoked action.

Return This function returns a future representing the result of the overall folding operation.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- `init`: [in] The initial value to be used for the folding operation
- `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>hpx::f

Perform a distributed inverse folding operation.

The function hpx::lcos::inverse_fold_with_index performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Note The type of the initial value must be convertible to the result type returned from the invoked action.

Return This function returns a future representing the result of the overall folding operation.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- `init`: [in] The initial value to be used for the folding operation
- `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

Functions

template<typename **T**>
hpx::future<*std*::vector<decay_t<*T*>>> **gather_here**(char **const** **basename*, *T* &&*result*, *num_sites_arg num_sites* = *num_sites_arg*(), *this_site_arg this_site* = *this_site_arg*(), *generation_arg generation* = *generation_arg*())

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Parameters

- `basename`: The base name identifying the gather operation
- `result`: The value to transmit to the central gather point from this call site.
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**>
hpx::future<*std*::vector<decay_t<*T*>>> **gather_here**(communicator *comm*, *T* &&*result*, *this_site_arg this_site* = *this_site_arg*())

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_reducer*

- `result`: The value to transmit to the central gather point from this call site.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**>
hpx::future<*std*::vector<decay_t<*T*>>> **gather_there**(char **const** **basename*, *T* &&*result*, *this_site_arg this_site* = *this_site_arg*(), *generation_arg generation* = *generation_arg*(), *root_site_arg root_site* = *root_site_arg*())

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

Return This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Parameters

- `basename`: The base name identifying the gather operation
- `result`: The value to transmit to the central gather point from this call site.
- `generation`: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- `root_site`: The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

template<typename **T**>
hpx::future<*std*::vector<decay_t<*T*>>> **gather_there**(communicator *comm*, *T* &&*result*, *this_site_arg this_site* = *this_site_arg*())

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

Return This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_reducer*
- `result`: The value to transmit to the central gather point from this call site.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace collectives

Functions

template<typename **T**, typename **F**>
hpx::future<*std*::decay_t<*T*>> **inclusive_scan**(char **const** **basename*, *T* &&*result*, *F* &&*op*, *num_sites_arg num_sites = num_sites_arg*(), *this_site_arg this_site = this_site_arg*(), *generation_arg generation = generation_arg*(), *root_site_arg root_site = root_site_arg*())

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

Parameters

- `basename`: The base name identifying the inclusive_scan operation
- `local_result`: The value to transmit to all participating sites from this call site.
- `op`: Reduction operation to apply to all values supplied from all participating sites
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive_scan operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. \params root_site The site that is responsible for creating the inclusive_scan support object. This value is optional and defaults to '0' (zero).

template<typename **T**, typename **F**>
hpx::future<*std*::decay_t<*T*>> **inclusive_scan**(communicator *comm*, *T* &&*result*, *F* &&*op*, *this_site_arg this_site = this_site_arg*())

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_reducer*
- `local_result`: The value to transmit to all participating sites from this call site.
- `op`: Reduction operation to apply to all values supplied from all participating sites
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace distributed

class latch : **public** *components*::client_base<*latch*, *hpx*::*lcos*::*server*::latch>

Public Functions

latch()

latch(*std*::ptrdiff_t *count*)
Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.

latch(*hpx*::*id_type* **const** &*id*)
Extension: Create a client side representation for the existing *server::latch* instance with the given global id *id*.

latch(*hpx*::future<*hpx*::*id_type*> &&*f*)
Extension: Create a client side representation for the existing *server::latch* instance with the given global id *id*.

latch(*hpx*::shared_future<*hpx*::*id_type*> **const** &*id*)
Extension: Create a client side representation for the existing *server::latch* instance with the given global id *id*.

latch(*hpx*::shared_future<*hpx*::*id_type*> &&*id*)

void **count_down_and_wait**()
Decrements counter_ by 1 . Blocks at the synchronization point until counter_ reaches 0.

Requires: counter_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

Exceptions
- `Nothing.`:

void **arrive_and_wait**()
Decrements counter_ by update . Blocks at the synchronization point until counter_ reaches 0.

Requires: counter_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

Exceptions
- `Nothing.`:

void **count_down**(*std*::ptrdiff_t *n*)
Decrements counter_ by n. Does not block.

Requires: counter_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true .

Exceptions
- `Nothing.`:

bool **is_ready**() **const**
Returns: counter_ == 0. Does not block.

Exceptions
- `Nothing.`:

bool **try_wait**() **const**
Returns: counter_ == 0. Does not block.

Exceptions
- `Nothing.`:

void **wait**() **const**
If counter_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter_ reaches 0.

Exceptions
- `Nothing.`:

Reduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters
- `basename`: The base name identifying the all_reduce operation
- `local_result`: A value to reduce on the central reduction point from this call site.
- `op`: Reduction operation to apply to all values supplied from all participating sites
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**, typename **F**>

hpx::future<decay_t<*T*>> **reduce_here**(communicator *comm*, *T* &&*local_result*, *F* &&*op*, *this_site_arg this_site* = *this_site_arg*())

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

Return This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_communicator*
- `local_result`: A value to reduce on the root_site from this call site.
- `op`: Reduction operation to apply to all values supplied from all participating sites
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename **T**, typename **F**>

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Return This function returns a future<void>. It will become ready once the reduction operation has been completed.

Parameters

- `basename`: The base name identifying the reduction operation
- `result`: A future referring to the value to transmit to the central reduction point from this call site.
- `generation`: The generational counter identifying the sequence number of the reduction operation performed on the given base name. This is optional and needs to be supplied only if the reduction operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- `root_site`: The sequence number of the central reduction point (usually the locality id). This value is optional and defaults to 0.

template<typename **T**>
hpx::future<void> **reduce_there**(communicator *comm*, *T* &&*local_result*, *this_site_arg this_site* = *this_site_arg*())

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Return This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters

- `comm`: A communicator object returned from *create_communicator*
- `local_result`: A value to reduce on the central reduction point from this call site.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace lcos

Functions

template<typename Action, typename ReduceOp, typename ArgN, ...>hpx::future<decltyp

Perform a distributed reduction operation.

The function hpx::lcos::reduce performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

Return This function returns a future representing the result of the overall reduction operation.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `reduce_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- `argN`: [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.

template<typename Action, typename ReduceOp, typename ArgN, ...>hpx::future<decltyp

Perform a distributed reduction operation.

The function hpx::lcos::reduce_with_index performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Return This function returns a future representing the result of the overall reduction operation.

Parameters

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `reduce_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- `argN`: [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.

namespace hpx

Functions

template<typename **Client**>
std::vector<*Client*> **find_all_from_basename**(*std*::string *base_name*, *std*::size_t *num_ids*)

Return all registered clients from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered ids from all localities from the given base name.

Return A list of futures representing the ids which were registered using the given base name.

Note The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters

- `Client`: The client type to return

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `num_ids`: [in] The number of registered ids to expect.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return A list of futures representing the ids which were registered using the given base name.

Note The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `num_ids`: [in] The number of registered ids to expect.

template<typename **Client**>
std::vector<*Client*> **find_from_basename**(*std*::string *base_name*, *std*::vector<*std*::size_t> **const** &*ids*)

Return registered clients from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return registered ids from the given base name and sequence numbers.

Return A list of futures representing the ids which were registered using the given base name and sequence numbers.

Note The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters

- `Client`: The client type to return

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `ids`: [in] The sequence numbers of the registered ids.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return A list of futures representing the ids which were registered using the given base name and sequence numbers.

Note The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `ids`: [in] The sequence numbers of the registered ids.

template<typename **Client**>
Client **find_from_basename**(*std*::string *base_name*, *std*::size_t *sequence_nr*)

Return registered id from the given base name and sequence number.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

Return A representing the id which was registered using the given base name and sequence numbers.

Note The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters

- `Client`: The client type to return

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `sequence_nr`: [in] The sequence number of the registered id.

Return A representing the id which was registered using the given base name and sequence numbers.

Note The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `sequence_nr`: [in] The sequence number of the registered id.

template<typename **Client**, typename **Stub**>
hpx::future<bool> **register_with_basename**(*std*::string *base_name*, *components*::client_base<*Client*, *Stub*> &*client*, *std*::size_t *sequence_nr*)

Register the id wrapped in the given client using the given base name.

The function registers the object the given client refers to using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Template Parameters

- `Client`: The client type to register

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `client`: [in] The client which should be registered using the given base name.
- `sequence_nr`: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

template<typename **Client**>
Client **unregister_with_basename**(*std*::string *base_name*, *std*::size_t *sequence_nr*)

Unregister the given id using the given base name.

Unregister the given base name.

The function unregisters the given ids using the provided base name.

The function unregisters the given ids using the provided base name.

Return A future representing the result of the un-registration operation itself.

Template Parameters

- `Client`: The client type to return

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `sequence_nr`: [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register_with_basename* before.

Return A future representing the result of the un-registration operation itself.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `sequence_nr`: [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register_with_basename* before.

namespace hpx

Functions

hpx::future<bool> **register_with_basename**(*std*::string *base_name*, *hpx*::*id_type* *id*, *std*::size_t *sequence_nr* = ~static_cast<*std*::size_t>(0))

Register the given id using the given base name.

The function registers the given ids using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `id`: [in] The id to register using the given base name.
- `sequence_nr`: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

hpx::future<bool> **register_with_basename**(*std*::string *base_name*, *hpx*::future<*hpx*::*id_type*> *f*, *std*::size_t *sequence_nr* = ~static_cast<*std*::size_t>(0))

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `f`: [in] The future which should be registered using the given base name.
- `sequence_nr`: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

namespace hpx

Functions

template<typename **Component**>
hpx::future<*std*::shared_ptr<*Component*>> **get_ptr** (*hpx*::*id_type* **const** &*id*)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

Return This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

Note This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

- `id`: [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

Template Parameters

- `The`: only template parameter has to be the type of the server side component.

template<typename **Derived**, typename **Stub**>
hpx::future<*std*::shared_ptr<**typename** *components*::client_base<*Derived*, *Stub*>::*server_component_type*>> **get_ptr** (*compo*
Stub>
cons
&*c*)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

Return This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

Note This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

- `c`: [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

template<typename **Component**>
std::shared_ptr<*Component*> **get_ptr**(*launch*::sync_policy *p*, *hpx*::*id_type* **const** &*id*, *error_code* &*ec* = *throws*)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

Return This function returns the pointer to the underlying memory for the component instance with the given *id*.

Note This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise and error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `p`: [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- `id`: [in] The global id of the component for which the pointer to the underlying memory should be retrieved.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Template Parameters

- `The`: only template parameter has to be the type of the server side component.

template<typename **Derived**, typename **Stub**>
std::shared_ptr<**typename** *components*::client_base<*Derived*, *Stub*>::*server_component_type*> **get_ptr**(*launch*::sync_policy *p*, *components*::client_base<*Derived*, *Stub*> **const** &*c*, *error_code* &*ec* = *throws*)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

Return This function returns the pointer to the underlying memory for the component instance with the given *id*.

Note This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise and error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `p`: [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- `c`: [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

namespace hpx

namespace components

struct component_commandline : **public** *component_commandline_base*

#include <component_commandline.hpp> The component_startup_shutdown provides a minimal implementation of a component's startup/shutdown function provider.

Public Functions

hpx::*program_options*::*options_description* **add_commandline_options**()

Return any additional command line options valid for this component.

Return The module is expected to fill a options_description object with any additional command line options this component will handle.

Note This function will be executed by the runtime system during system startup.

template<bool(*)(startup_function_type &, bool &) Startup, bool(*)(shutdown_functio

#include <component_startup_shutdown.hpp> The component_startup_shutdown class provides a minimal implementation of a component's startup/shutdown function provider.

Public Functions

bool **get_startup_function**(*startup_function_type &startup*, bool *&pre_startup*)

Return any startup function for this component.

Return Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

Parameters

- `startup`: [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

bool **get_shutdown_function**(*shutdown_function_type &shutdown*, bool *&pre_shutdown*)

Return any startup function for this component.

Return Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

Parameters

- `shutdown`: [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

namespace naming

Functions

std::ostream &**operator<<**(*std*::ostream&, *address* **const**&)

namespace hpx

namespace components

Typedefs

typedef abstract_component_base<Component> **instead**

template<typename **Component**, typename **Derived**>
class managed_component

#include <managed_component_base.hpp> The *managed_component* template is used as a indirection layer for components allowing to gracefully handle the access to non-existing components.

Additionally it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a *managed_component* gets assigned a global id. The provided memory management allocates the *managed_component* instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.

Template Parameters

- `Component`:
- `Derived`:

namespace hpx

namespace util

class unique_id_ranges

#include <generate_unique_ids.hpp> The *unique_id_ranges* class is a type responsible for generating unique ids for components, parcels, threads etc.

Public Functions

unique_id_ranges()

naming::*gid_type* **get_id**(*std*::size_t *count* = 1)

Generate next unique component id.

void **set_range**(*naming*::*gid_type* **const** &*lower*, *naming*::*gid_type* **const** &*upper*)

Private Types

enum [anonymous]

size of the id range returned by command_getidrange FIXME: is this a policy?

Values:

range_delta = 0x100000

using mutex_type = *hpx*::*util*::*spinlock*

Private Members

mutex_type **mtx_**

naming::*gid_type* **lower_**
The range of available ids for components.

naming::*gid_type* **upper_**

namespace hpx

template<typename **Component**, typename **Enable** = void>
struct get_lva
#include <get_lva.hpp> The get_lva template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function *resolver_client::resolve*) to the address of the component implementing the action.

The default implementation uses the template argument *Component* to deduce the type wrapping the component implementing the action. This is used to get the needed address.

Template Parameters

- `Component`: This is the type of the component implementing the action to execute.

~vector()

vector &**operator=**(vector **const** &*other*)

vector &**operator=**(vector &&*other*)

allocator_type **get_allocator**() **const**
Returns the allocator associated with the container.

reference **operator[]**(size_type *pos*)

const_reference **operator[]**(size_type *pos*) **const**

pointer **data**()
Returns pointer to the underlying array serving as element storage. The pointer is such that range [*data()*; *data()* + size()) is always a valid range, even if the container is empty (*data()* is not dereferenceable in that case).

const_pointer **data**() **const**
Returns pointer to the underlying array serving as element storage. The pointer is such that range [*data()*; *data()* + size()) is always a valid range, even if the container is empty (*data()* is not dereferenceable in that case).

T ***device_data*() **const**
Returns a raw pointer corresponding to the address of the data allocated on the device.

std::size_t **size**() **const**

std::size_t **capacity**() **const**

bool **empty**() **const**
Returns: size() == 0.

void **resize**(size_type)
Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() default-inserted elements to the sequence.

Requires: T shall be MoveInsertable and DefaultInsertable into *this.

Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

void **resize**(size_type, T **const**&)
Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() copies of val to the sequence.

Requires: T shall be CopyInsertable into *this.

Remarks: If an exception is thrown there are no effects.

iterator **begin**()

iterator **end**()

const_iterator **cbegin**() **const**

const_iterator **cend**() **const**

const_iterator **begin**() **const**

const_iterator **end**() **const**

void **swap**(vector &*other*)
Effects: Exchanges the contents and capacity() of *this with that of x.

Complexity: Constant time.

void **clear**()
Effects: Erases all elements in the range [begin(),end()). Destroys all elements in a. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.

Post: a.empty() returns true.

Complexity: Linear.

distribution_policies

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace components

Variables

constexpr char **const** ***const default_binpacking_counter_name** = "/runtime{locality/total}/count/compo

const *binpacking_distribution_policy* **binpacked** = {}
A predefined instance of the binpacking *distribution_policy*. It will represent the local locality and will place all items to create here.

struct binpacking_distribution_policy
#include <binpacking_distribution_policy.hpp> This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).

Public Functions

binpacking_distribution_policy()
Default-construct a new instance of a binpacking_distribution_policy. This policy will represent one locality (the local locality).

binpacking_distribution_policy **operator()**(*std*::vector<*id_type*> **const** *&locs*, char **const** **perf_counter_name* = *default_binpacking_counter_name*) **const**
Create a new *default_distribution* policy representing the given set of localities.

Parameters
- `locs`: [in] The list of localities the new instance should represent

- `perf_counter_name`: [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

binpacking_distribution_policy **operator()**(*std*::vector<*id_type*> &&*locs*, char **const** **perf_counter_name* = *default_binpacking_counter_name*) **const**

Create a new *default_distribution* policy representing the given set of localities.

Parameters

- `locs`: [in] The list of localities the new instance should represent
- `perf_counter_name`: [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

binpacking_distribution_policy **operator()**(*id_type* **const** &*loc*, char **const** **perf_counter_name* = *default_binpacking_counter_name*) **const**

Create a new *default_distribution* policy representing the given locality

Parameters

- `loc`: [in] The locality the new instance should represent
- `perf_counter_name`: [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

template<typename **Component**, typename ...**Ts**>
hpx::future<*hpx*::*id_type*> **create**(*Ts*&&... *vs*) **const**

Create one object on one of the localities associated by this policy instance

Return A future holding the global address which represents the newly created object

Parameters

- `vs`: [in] The arguments which will be forwarded to the constructor of the new object.

template<typename **Component**, typename ...**Ts**>
hpx::future<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t *count*, *Ts*&&... *vs*) **const**

Create multiple objects on the localities associated by this policy instance

Return A future holding the list of global addresses which represent the newly created objects

Parameters

- `count`: [in] The number of objects to create
- `vs`: [in] The arguments which will be forwarded to the constructors of the new objects.

std::string **const** &**get_counter_name**() **const**

Returns the name of the performance counter associated with this policy instance.

std::size_t **get_num_localities**() **const**

Returns the number of associated localities for this distribution policy

Note This function is part of the creation policy implemented by this class

namespace hpx

namespace components

Variables

const *colocating_distribution_policy* **colocated** = {}
A predefined instance of the co-locating *distribution_policy*. It will represent the local locality and will place all items to create here.

struct colocating_distribution_policy
#include <colocating_distribution_policy.hpp> This class specifies the parameters for a distribution policy to use for creating a given number of items on the locality where a given object is currently placed.

Public Functions

colocating_distribution_policy()
Default-construct a new instance of a colocating_distribution_policy. This policy will represent the local locality.

colocating_distribution_policy **operator()**(*id_type* **const** &*id*) **const**
Create a new colocating_distribution_policy representing the locality where the given object is current located

Parameters
- `id`: [in] The global address of the object with which the new instances should be colocated on

template<typename **Client**, typename **Stub**>
colocating_distribution_policy **operator()**(client_base<*Client*, *Stub*> **const** &*client*) **const**
Create a new colocating_distribution_policy representing the locality where the given object is current located

Parameters
- `client`: [in] The client side representation of the object with which the new instances should be colocated on

template<typename **Component**, typename ...**Ts**>
hpx::future<*hpx*::*id_type*> **create**(*Ts*&&... *vs*) **const**
Create one object on the locality of the object this distribution policy instance is associated with

Note This function is part of the placement policy implemented by this class
Return A future holding the global address which represents the newly created object
Parameters
- `vs`: [in] The arguments which will be forwarded to the constructor of the new object.

template<typename **Component**, typename ...**Ts**>
hpx::future<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t *count*, *Ts*&&... *vs*) **const**
Create multiple objects colocated with the object represented by this policy instance

Note This function is part of the placement policy implemented by this class

Return A future holding the list of global addresses which represent the newly created objects
Parameters
- `count`: [in] The number of objects to create
- `vs`: [in] The arguments which will be forwarded to the constructors of the new objects.

template<typename **Action**, typename ...**Ts**>
async_result<*Action*>::*type* **async**(*launch policy*, *Ts*&&... *vs*) **const**

Variables

const *target_distribution_policy* **target** = { }
A predefined instance of the target_distribution_policy. It will represent the local locality and will place all items to create here.

struct target_distribution_policy
#include <target_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

target_distribution_policy()
Default-construct a new instance of a target_distribution_policy. This policy will represent one locality (the local locality).

target_distribution_policy **operator()** (*id_type* **const** &*id*) **const**
Create a new target_distribution_policy representing the given locality

Parameters
- `loc`: [in] The locality the new instance should represent

template<typename **Component**, typename ...**Ts**>
hpx::future<*hpx*::*id_type*> **create** (*Ts*&&... *vs*) **const**
Create one object on one of the localities associated by this policy instance

Note This function is part of the placement policy implemented by this class
Return A future holding the global address which represents the newly created object
Parameters
- `vs`: [in] The arguments which will be forwarded to the constructor of the new object.

template<typename **Component**, typename ...**Ts**>
hpx::future<*std*::vector<bulk_locality_result>> **bulk_create** (*std*::size_t *count*, *Ts*&&... *vs*) **const**
Create multiple objects on the localities associated by this policy instance

namespace hpx

Functions

int **finalize**(double *shutdown_timeout*, double *localwait* = -1.0, *error_code* &*ec* = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function *hpx::finalize* is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on all localities.

The default value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter `hpx.shutdown_timeout`), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

Parameters

- `shutdown_timeout`: This parameter allows to specify a timeout (in microseconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

The default value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter "hpx.finalize_wait_time"), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

Parameters

- `localwait`: This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Return This function will always return zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Using this function is an alternative to *hpx::disconnect*, these functions do not need to be called both.

int **finalize**(*error_code* &*ec* = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function *hpx::finalize* is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on all localities.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Return This function will always return zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Using this function is an alternative to *hpx::disconnect*, these functions do not need to be called both.

void **`terminate`**`()`

Terminate any application non-gracefully.

The function *hpx::terminate* is the non-graceful way to exit any application immediately. It can be called from any locality and will terminate all localities currently used by the application.

Note This function will cause HPX to call `std::terminate()` on all localities associated with this application. If the function is called not from an HPX thread it will fail and return an error using the argument *ec*.

int **`disconnect`**`(`double *shutdown_timeout*, double *localwait* = -1.0, *error_code* &*ec* = *throws*`)`

Disconnect this locality from the application.

The function *hpx::disconnect* can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on this locality. The default value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter "hpx.shutdown_timeout"), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

Parameters

- `shutdown_timeout`: This parameter allows to specify a timeout (in microseconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

The default value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter `hpx.finalize_wait_time`), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

Parameters

- `localwait`: This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

Return This function will always return zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

int **`disconnect`**(*error_code &ec = throws*)

Disconnect this locality from the application.

The function *hpx::disconnect* can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on this locality.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

Return This function will always return zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

int **`stop`**(*error_code &ec = throws*)

Stop the runtime system.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called on every locality. This function should be used only if the runtime system was started using `hpx::start`.

Return The function returns the value, which has been returned from the user supplied main HPX function (usually `hpx_main`).

`namespace hpx`

Functions

int **`init`**(*std*::function<int) *hpx*::*program_options*::*variables_map&*
> *f*, int *argc*, char ***argv*, *init_params* **`const`** *&params* = *init_params*()Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

Return The function returns the value, which has been returned from the user supplied `f`.

Note If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise it will be executed as specified by the parameter`mode`.

Parameters

- `f`: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the *hpx::init* function (See documentation of hpx::init_params)

int **`init`** (*std*::function<int) int, char**
> *f*, int *argc*, char ***argv*, *init_params* **`const`** &*params* = *init_params*()Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

- `params`: [in] The parameters to the *hpx::init* function (See documentation of hpx::init_params)

int **`init`**(*init_params* **`const`** &*params* = *init_params*())

Main entry point for launching the HPX runtime system.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

Return The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

Note The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. If not command line arguments are passed, console mode is assumed.

Note If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

- `params`: [in] The parameters to the *hpx::init* function (See documentation of hpx::init_params)

namespace hpx

struct init_params

Parameters

- `f`: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the *hpx::start* function (See documentation of hpx::init_params)

bool **start**(int *argc*, char ***argv*, *init_params* **const** &*params* = *init_params*())
Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use

`hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

Return The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

Note If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise it will be executed as specified by the parameter`mode`.

Parameters

- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the *hpx::start* function (See documentation of hpx::init_params)

bool **`start`**(*std*::nullptr_t *f*, int *argc*, char ***argv*, *init_params* **`const`** &*params* = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

Return The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

Note If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise it will be executed as specified by the parameter`mode`.

Parameters

- `f`: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the *hpx::start* function (See documentation of hpx::init_params)

bool **start** (*init_params* **const** *&params* = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is a simplified main, non-blocking entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

Return The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

Note The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. If not command line arguments are passed, console mode is assumed.

Note If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

- `params`: [in] The parameters to the *hpx::start* function (See documentation of hpx::init_params)

namespace hpx

Functions

int **suspend** (*error_code &ec* = *throws*)

Suspend the runtime system.

The function *hpx::suspend* is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

Return This function will always return zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

int **resume** (*error_code &ec* = *throws*)

Resume the HPX runtime system.

The function *hpx::resume* is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

Return This function will always return zero.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Functions

hpx::*id_type* **unmanaged**(*hpx*::*id_type* **const** &*id*)

The helper function *hpx::unmanaged* can be used to generate a global identifier which does not participate in the automatic garbage collection.

Return This function returns a new global id referencing the same object as the parameter *id*. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

Note This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

Parameters

- `id`: [in] The id to generated the unmanaged global id from This parameter can be itself a managed or a unmanaged global id.

namespace hpx

namespace parcelset

Typedefs

using parcel_write_handler_type = *hpx*::function<void(*std*::error_code **const**&, *parcelset*::parcel **const**&)>

The type of a function that can be registered as a parcel write handler using the function *hpx::set_parcel_write_handler*.

Note A parcel write handler is a function which is called by the parcel layer whenever a parcel has been sent by the underlying networking library and if no explicit parcel handler function was specified for the parcel.

Enums

enum parcelport_background_mode

Type of background work to perform.

Values:

parcelport_background_mode_flush_buffers = 0x01
perform buffer flush operations

parcelport_background_mode_send = 0x03
perform send operations (includes buffer flush)

parcelport_background_mode_receive = 0x04
perform receive operations

parcelport_background_mode_all = 0x07
perform all operations

Functions

bool **default_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discovery function for performance counters; to be registered with the counter types. It will pass the counter_info and the *error_code* to the supplied function.

bool **locality_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/total)/<instancename>

bool **locality_pool_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/pool#<pool_name>/total)/<instancename>

bool **locality0_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discoverer function for AGAS performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>{locality#0/total}/<instancename>

bool **locality_thread_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/worker-thread#<threadnum>)/<instancename>

bool **locality_pool_thread_counter_discoverer**(*counter_info* **const** &*info*, *discover_counter_func* **const** &*f*, *discover_counters_mode* *mode*, *error_code* &*ec*)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>{locality#<locality_id>/pool#<poolname>/thread#<threadnum>}/<instancename>

bool **locality_pool_thread_no_total_counter_discoverer**(*counter_info* **const** &*info*, *discover_counter_func* **const** &*f*, *discover_counters_mode* *mode*, *error_code* &*ec*)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>{locality#<locality_id>/pool#<poolname>/thread#<threadnum>}/<instancename>

This is essentially the same as above just that locality#*/total is not supported.

bool **locality_numa_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/numa-node#<threadnum>)/<instancename>

naming::*gid_type* **locality_raw_counter_creator**(*counter_info* **const**&, *hpx*::function<*std*::int64_t) bool > **const**&, *error_code*&Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

/<objectname>(locality#<locality_id>/total)/<instancename>

naming::*gid_type* **locality_raw_values_counter_creator**(*counter_info* **const**&, *hpx*::function<*std*::vector<*std*::int64_t>) bool > **const**&, *error_code*&

naming::*gid_type* **agas_raw_counter_creator**(*counter_info* **const**&, *error_code*&, char **const***const)

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

/agas(<objectinstance>/total)/<instancename>

bool **agas_counter_discoverer**(*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/agas(<objectinstance>/total)/<instancename>

naming::*gid_type* **local_action_invocation_counter_creator**(*counter_info* **const**&, *error_code*&)

Typedefs

typedef *hpx*::function<*naming*::*gid_type* (*counter_info* **const**&, *error_code*&)> **create_counter_func**

This declares the type of a function, which will be called by HPX whenever a new performance counter instance of a particular type needs to be created.

typedef *hpx*::function<bool (*counter_info* **const**&, *error_code*&)> **discover_counter_func**

This declares a type of a function, which will be passed to a *discover_counters_func* in order to be called for each discovered performance counter instance.

typedef *hpx*::function<bool (*counter_info* **const**&, *discover_counter_func* **const**&, *discover_counters_mode*, *error_code*&)> **discover_counters_func**

This declares the type of a function, which will be called by HPX whenever it needs to discover all performance counter instances of a particular type.

Enums

enum counter_type

Values:

counter_text

counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

counter_raw

counter_raw shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

counter_monotonically_increasing

counter_average_base
counter_average_base is used as the base data (denominator) in the computation of time or count averages for the *counter_average_count* and *counter_average_timer* counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

counter_average_count
counter_average_count shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: (N1 - N0) / (D1 - D0), where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average: (Nx - N0) / (Dx - D0) Type: Average

counter_aggregating
counter_aggregating applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: F(Nx)

counter_average_timer
counter_average_timer measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: ((N1 - N0) / F) / (D1 - D0), where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. Average: ((Nx - N0) / F) / (Dx - D0) Type: Average

counter_elapsed_time
counter_elapsed_time shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: (D0 - N0) / F, where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average: (Dx - N0) / F Type: Difference

counter_histogram
counter_histogram exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter_value_array* instead of a counter_value. Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

counter_raw_values
counter_raw_values exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter_value_array* instead of a

counter_value. Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

counter_text
counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

counter_raw
counter_raw shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

counter_monotonically_increasing

counter_average_base
counter_average_base is used as the base data (denominator) in the computation of time or count averages for the *counter_average_count* and *counter_average_timer* counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

counter_average_count

Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

enum counter_status
Status and error codes used by the functions related to performance counters.

Values:

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

Counters of this type expose a *counter_value_array* instead of a counter_value. Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

counter_raw_values

counter_raw_values exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter_value_array* instead of a counter_value. Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

enum counter_status

Values:

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

enum discover_counters_mode
Values:

discover_counters_minimal

discover_counters_full

Functions

counter_status **get_counter_type_name**(*counter_type_path_elements* **const** *&path*, *std*::string *&result*, *error_code &ec = throws*)
Create a full name of a counter type from the contents of the given counter_type_path_elements instance.The generated counter type name will not contain any parameters.

counter_status **get_full_counter_type_name**(*counter_type_path_elements* **const** *&path*, *std*::string *&result*, *error_code &ec = throws*)
Create a full name of a counter type from the contents of the given counter_type_path_elements instance. The generated counter type name will contain all parameters.

counter_status **get_counter_name**(*counter_path_elements* **const** *&path*, *std*::string *&result*, *error_code &ec = throws*)

Create a full name of a counter from the contents of the given counter_path_elements instance.

counter_status **get_counter_instance_name**(*counter_path_elements* **const** *&path*, *std*::string *&result*, *error_code &ec = throws*)

Create a name of a counter instance from the contents of the given counter_path_elements instance.

counter_status **get_counter_type_path_elements**(*std*::string **const** *&name*, *counter_type_path_elements &path*, *error_code &ec = throws*)

Fill the given counter_type_path_elements instance from the given full name of a counter type.

counter_status **get_counter_path_elements**(*std*::string **const** *&name*, *counter_path_elements &path*, *error_code &ec = throws*)

Fill the given counter_path_elements instance from the given full name of a counter.

counter_status **get_counter_name**(*std*::string **const** *&name*, *std*::string *&countername*, *error_code &ec = throws*)

Return the canonical counter instance name from a given full instance name.

counter_status **get_counter_type_name**(*std*::string **const** *&name*, *std*::string *&type_name*, *error_code &ec = throws*)

Return the canonical counter type name from a given (full) instance name.

counter_status **complement_counter_info**(*counter_info &info*, *counter_info* **const** *&type_info*, *error_code &ec = throws*)

Complement the counter info if parent instance name is missing.

counter_status **complement_counter_info**(*counter_info &info*, *error_code &ec = throws*)

counter_status **add_counter_type**(*counter_info* **const** *&info*, *create_counter_func* **const** *&create_counter*, *discover_counters_func* **const** *&discover_counters*, *error_code &ec = throws*)

counter_status **discover_counter_types**(*discover_counter_func* **const** *&discover_counter*, *discover_counters_mode mode = discover_counters_minimal*, *error_code &ec = throws*)

Call the supplied function for each registered counter type.

counter_status **discover_counter_types**(*std*::vector<*counter_info*> *&counters*, *discover_counters_mode mode = discover_counters_minimal*, *error_code &ec = throws*)

Return a list of all available counter descriptions.

counter_status **discover_counter_type**(*std*::string **const** *&name*, *discover_counter_func* **const** *&discover_counter*, *discover_counters_mode mode = discover_counters_minimal*, *error_code &ec = throws*)

Call the supplied function for the given registered counter type.

counter_status **discover_counter_type**(*counter_info* **const** *&info*, *discover_counter_func* **const** *&discover_counter*, *discover_counters_mode mode = discover_counters_minimal*, *error_code &ec = throws*)

counter_status **discover_counter_type**(*std*::string **const** *&name*, *std*::vector<*counter_info*> *&counters*, *discover_counters_mode mode* = *discover_counters_minimal*, *error_code &ec* = *throws*)

Return a list of matching counter descriptions for the given registered counter type.

counter_status **discover_counter_type**(*counter_info* **const** *&info*, *std*::vector<*counter_info*> *&counters*, *discover_counters_mode mode* = *discover_counters_minimal*, *error_code &ec* = *throws*)

bool **expand_counter_info**(*counter_info* **const**&, *discover_counter_func* **const**&, *error_code*&)

call the supplied function will all expanded versions of the supplied counter info.

This function expands all locality#* and worker-thread#* wild cards only.

counter_status **remove_counter_type**(*counter_info* **const** *&info*, *error_code &ec* = *throws*)

Remove an existing counter type from the (local) registry.

Note This doesn't remove existing counters of this type, it just inhibits defining new counters using this type.

counter_status **get_counter_type**(*std*::string **const** *&name*, *counter_info &info*, *error_code &ec* = *throws*)

Retrieve the counter type for the given counter name from the (local) registry.

hpx::future<*hpx*::*id_type*> **get_counter_async**(*std*::string *name*, *error_code &ec* = *throws*)

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter name.

hpx::future<*hpx*::*id_type*> **get_counter_async**(*counter_info* **const** *&info*, *error_code &ec* = *throws*)

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter info.

void **get_counter_infos**(*counter_info* **const** *&info*, *counter_type &type*, *std*::string *&helptext*, *std*::uint32_t *&version*, *error_code &ec* = *throws*)

Retrieve the meta data specific for the given counter instance.

void **get_counter_infos**(*std*::string *name*, *counter_type &type*, *std*::string *&helptext*, *std*::uint32_t *&version*, *error_code &ec* = *throws*)

Retrieve the meta data specific for the given counter instance.

struct counter_value

Public Functions

counter_value(*std*::int64_t *value* = 0, *std*::int64_t *scaling* = 1, bool *scale_inverse* = false)

template<typename **T**>

T **get_value**(*error_code &ec* = *throws*) **const**

Retrieve the 'real' value of the *counter_value*, converted to the requested type *T*.

Public Members

std::uint64_t **time_**
The local time when data was collected.

std::uint64_t **count_**
The invocation counter for the data.

std::int64_t **value_**
The current counter value.

std::int64_t **scaling_**
The scaling of the current counter value.

counter_status **status_**
The status of the counter value.

bool **scale_inverse_**
If true, value_ needs to be divided by scaling_, otherwise it has to be multiplied.

Private Functions

void **serialize**(*serialization*::*output_archive* &*ar*, **const** unsigned int)

void **serialize**(*serialization*::*input_archive* &*ar*, **const** unsigned int)

Friends

namespace hpx

namespace agas

Functions

void **locality_namespace_register_counter_types**(*error_code* &*ec* = *throws*)

namespace hpx

namespace performance_counters

Functions

void **install_counter**(*hpx*::*id_type* **const** &*id*, *counter_info* **const** &*info*, *error_code* &*ec* = *throws*)
Install a new performance counter in a way, which will uninstall it automatically during shutdown.

namespace hpx

namespace performance_counters

Functions

counter_status **install_counter_type**(*std*::string **const** &*name*, *hpx*::function<*std*::int64_t) bool > **const** &*counter_value*, *std*::string **const** &*helptext* = "", *std*::string **const** &*uom* = "", *counter_type type* = *counter_raw*, *error_code* &*ec* = *throws*Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install_counter_type* will register a new generic counter type based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this this counter type will cause the provided function to be called and the returned value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `'/objectname{locality#<*>/total}/countername'` where '<*>' is a zero based integer identifying the locality the counter is created on.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Return If successful, this function returns *status_valid_data*, otherwise it will either throw an exception or return an error_code from the enum *counter_status* (also, see note related to parameter *ec*).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Parameters

- `name`: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- `counter_value`: [in] The function to call whenever the counter value is requested by a consumer.
- `helptext`: [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- `uom`: [in] The unit of measure for the new performance counter type.
- `type`: [in] Type for the new performance counter type.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

counter_status **install_counter_type**(*std*::string **const** &*name*, *hpx*::function<*std*::vector<*std*::int64_t>) bool > **const** &*counter_value*, *std*::string **const** &*helptext* = "", *std*::string **const** &*uom* = "", *error_code* &*ec* = *throws*Install a new generic performance counter type returning an array of values in a way, that will uninstall it automatically during shutdown.

The function *install_counter_type* will register a new generic counter type that returns an array of values based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this this counter type will cause the provided function to be called and the returned array value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `'/objectname{locality#<*>/total}/countername'` where '<*>' is a zero based integer identifying the locality the counter is created on.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Return If successful, this function returns *status_valid_data*, otherwise it will either throw an exception or return an error_code from the enum *counter_status* (also, see note related to parameter *ec*).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Parameters

- `name`: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- `counter_value`: [in] The function to call whenever the counter value (array of values) is requested by a consumer.
- `helptext`: [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- `uom`: [in] The unit of measure for the new performance counter type.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **install_counter_type**(*std*::string **const** &*name*, *counter_type type*, *error_code* &*ec* = *throws*)

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install_counter_type* will register a new counter type based on the provided *counter_type_info*. The counter type will be automatically unregistered during system shutdown.

Return If successful, this function returns *status_valid_data*, otherwise it will either throw an exception or return an error_code from the enum *counter_status* (also, see note related to parameter *ec*).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `name`: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- `type`: [in] The type of the counters of this counter_type.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

counter_status **install_counter_type**(*std*::string **const** &*name*, *counter_type type*, *std*::string **const** &*helptext*, *std*::string **const** &*uom* = "", *std*::uint32_t *version* = HPX_PERFORMANCE_COUNTER_V1, *error_code* &*ec* = *throws*)

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install_counter_type* will register a new counter type based on the provided *counter_type_info*. The counter type will be automatically unregistered during system shutdown.

Return If successful, this function returns *status_valid_data*, otherwise it will either throw an exception or return an error_code from the enum *counter_status* (also, see note related to parameter *ec*).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `name`: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- `type`: [in] The type of the counters of this counter_type.
- `helptext`: [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- `uom`: [in] The unit of measure for the new performance counter type.
- `version`: [in] The version of the counter type. This is currently expected to be set to HPX_PERFORMANCE_COUNTER_V1.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

counter_status **`install_counter_type`**(*std*::string **const** &*name*, *counter_type type*, *std*::string **const** &*helptext*, *create_counter_func* **const** &*create_counter*, *discover_counters_func* **const** &*discover_counters*, *std*::uint32_t *version* = HPX_PERFORMANCE_COUNTER_V1, *std*::string **const** &*uom* = "", *error_code* &*ec* = *throws*)

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install_counter_type* will register a new generic counter type based on the provided *counter_type_info*. The counter type will be automatically unregistered during system shutdown.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Return If successful, this function returns *status_valid_data*, otherwise it will either throw an exception or return an error_code from the enum *counter_status* (also, see note related to parameter *ec*).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Parameters

- `name`: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- `type`: [in] The type of the counters of this counter_type.
- `helptext`: [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- `version`: [in] The version of the counter type. This is currently expected to be set to HPX_PERFORMANCE_COUNTER_V1.
- `create_counter`: [in] The function which will be called to create a new instance of this counter type.
- `discover_counters`: [in] The function will be called to discover counter instances which can be created.
- `uom`: [in] The unit of measure of the counter type (default: "")
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

namespace hpx

namespace performance_counters

class registry

Public Functions

registry()

void **clear**()
Reset registry by deleting all stored counter types.

counter_status **add_counter_type**(*counter_info* **const** *&info*, *create_counter_func* **const** *&create_counter*, *discover_counters_func* **const** *&discover_counters*, *error_code &ec = throws*)
Add a new performance counter type to the (local) registry.

counter_status **discover_counter_types**(*discover_counter_func discover_counter*, *discover_counters_mode mode*, *error_code &ec = throws*)
Call the supplied function for all registered counter types.

counter_status **discover_counter_type**(*std*::string **const** *&fullname*, *discover_counter_func discover_counter*, *discover_counters_mode mode*, *error_code &ec = throws*)
Call the supplied function for the given registered counter type.

counter_status **discover_counter_type**(*counter_info* **const** *&info*, *discover_counter_func* **const** *&f*, *discover_counters_mode mode*, *error_code &ec = throws*)

counter_status **get_counter_create_function**(*counter_info* **const** *&info*, *create_counter_func &create_counter*, *error_code &ec = throws*) **const**
Retrieve the counter creation function which is associated with a given counter type.

counter_status **get_counter_discovery_function**(*counter_info* **const** *&info*, *discover_counters_func &func*, *error_code &ec*) **const**
Retrieve the counter discovery function which is associated with a given counter type.

counter_status **remove_counter_type**(*counter_info* **const** *&info*, *error_code &ec = throws*)
Remove an existing counter type from the (local) registry.

Note This doesn't remove existing counters of this type, it just inhibits defining new counters using this type.

counter_status **create_raw_counter_value**(*counter_info* **const** *&info*, *std*::int64_t **countervalue*, *naming*::*gid_type &id*, *error_code &ec = throws*)
Create a new performance counter instance of type raw_counter based on given counter value.

counter_status **create_raw_counter**(*counter_info* **const** &*info*, *hpx*::function<*std*::int64_t) > **const** &*f naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status **create_raw_counter**(*counter_info* **const** &*info*, *hpx*::function<*std*::int64_t) bool > **const** &*f*, *naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status **create_raw_counter**(*counter_info* **const** &*info*, *hpx*::function<*std*::vector<*std*::int64_t>) > **const** &*f naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status **create_raw_counter**(*counter_info* **const** &*info*, *hpx*::function<*std*::vector<*std*::int64_t>) bool > **const** &*f*, *naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status **create_counter**(*counter_info* **const** &*info*, *naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*)

Create a new performance counter instance based on given counter info.

counter_status **create_statistics_counter**(*counter_info* **const** &*info*, *std*::string **const** &*base_counter_name*, *std*::vector<*std*::size_t> **const** &*parameters*, *naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*)

Create a new statistics performance counter instance based on given base counter name and given base time interval (milliseconds).

counter_status **create_arithmetics_counter**(*counter_info* **const** &*info*, *std*::vector<*std*::string> **const** &*base_counter_names*, *naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*)

Create a new arithmetics performance counter instance based on given base counter names.

counter_status **create_arithmetics_counter_extended**(*counter_info* **const** &*info*, *std*::vector<*std*::string> **const** &*base_counter_names*, *naming*::*gid_type* &*id*, *error_code* &*ec* = *throws*)

Create a new extended arithmetics performance counter instance based on given base counter names.

counter_status **add_counter**(*hpx*::*id_type* **const** &*id*, *counter_info* **const** &*info*, *error_code* &*ec* = *throws*)

Add an existing performance counter instance to the registry.

counter_status **remove_counter**(*counter_info* **const** &*info*, *hpx*::*id_type* **const** &*id*, *error_code* &*ec* = *throws*)

remove the existing performance counter from the registry

counter_status **get_counter_type**(*std*::string **const** &*name*, *counter_info* &*info*, *error_code* &*ec* = *throws*)

Retrieve counter type information for given counter name.

plugin_factories

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_REGISTER_BINARY_FILTER_FACTORY(*BinaryFilter*, *pluginname*)
This macro is used create and to register a minimal component factory with Hpx.Plugin.

namespace hpx

namespace plugins

template<typename **BinaryFilter**>
struct binary_filter_factory : **public** *hpx::plugins::binary_filter_factory_base*
#include <binary_filter_factory.hpp> The *message_handler_factory* provides a minimal implementation of a message handler's factory. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a message handler's factory instance.

Template Parameters
- `BinaryFilter`: The message handler type this factory should be responsible for.

Public Functions

binary_filter_factory(*util::section* **const** **global*, *util::section* **const** **local*, bool *isenabled*)
Construct a new factory instance.

Note The contents of both sections has to be cloned in order to save the configuration setting for later use.
Parameters
- `global`: [in] The pointer to a *hpx::util::section* instance referencing the settings read from the [settings] section of the global configuration file (hpx.ini) This pointer may be nullptr if no such section has been found.
- `local`: [in] The pointer to a *hpx::util::section* instance referencing the settings read from the section describing this component type: [hpx.components.<name>], where <name> is the instance name of the component as given in the configuration files.

~binary_filter_factory()

serialization::binary_filter ***create**(bool *compress*, *serialization::binary_filter *next_filter* = nullptr)
Create a new instance of a message handler

return Returns the newly created instance of the message handler supported by this factory

Protected Attributes

util::*section* **global_settings_**

util::*section* **local_settings_**

bool **isenabled_**

Defines

HPX_REGISTER_BINARY_FILTER_FACTORY_BASE(*FactoryType*, *pluginname*)
This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the component factories.

namespace hpx

namespace plugins

struct binary_filter_factory_base : **public** *hpx*::*plugins*::*plugin_factory_base*
#include <*binary_filter_factory_base.hpp*> The plugin_factory_base has to be used as a base class for all plugin factories.

Subclassed by *hpx::plugins::binary_filter_factory< BinaryFilter >*

Public Functions

~binary_filter_factory_base()

virtual *serialization*::*binary_filter* ***create**(bool *compress*, *serialization*::*binary_filter* **next_filter* = nullptr) = 0
Create a new instance of a binary filter

return Returns the newly created instance of the binary filter supported by this factory

namespace hpx

namespace plugins

Functions

std::vector<*parcelport_factory_base**> &**get_parcelport_factories**()

void **add_parcelport_factory**(*parcelport_factory_base* **factory*)

struct parcelport_factory_base

runtime_components

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_REGISTER_COMPONENT (*type*, *name*, *mode*)

Define a component factory for a component type.

This macro is used create and to register a minimal component factory for a component type which allows it to be remotely created using the *hpx::new_<>* function.

This macro can be invoked with one, two or three arguments

Parameters

- `type`: The *type* parameter is a (fully decorated) type of the component type for which a factory should be defined.
- `name`: The *name* parameter specifies the name to use to register the factory. This should uniquely (system-wide) identify the component type. The *name* parameter must conform to the C++ identifier rules (without any namespace). If this parameter is not given, the first parameter is used.
- `mode`: The *mode* parameter has to be one of the defined enumeration values of the enumeration *hpx::components::factory_state_enum*. The default for this parameter is *hpx::components::factory_enabled*.

Defines

HPX_REGISTER_MINIMAL_COMPONENT_REGISTRY(...)
This macro is used create and to register a minimal component registry with Hpx.Plugin.

namespace hpx

namespace components

template<typename **Component**, *factory_state_enum* **state**>
struct component_registry : **public** *component_registry_base*
#include <*component_registry.hpp*> The component_registry provides a minimal implementation of a component's registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a component's registry instance.

Template Parameters
- `Component`: The component type this registry should be responsible for.

Public Functions

bool **get_component_info**(*std*::vector<*std*::string> &*fillini*, *std*::string **const** &*filepath*, bool *is_static* = false)
Return the ini-information for all contained components.

Return Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.
Parameters
- `fillini`: [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

void **register_component_type**()
Return the unique identifier of the component type this factory is responsible for.

Return Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.
Parameters
- `locality`: [in] The id of the locality this factory is responsible for.
- `agas_client`: [in] The AGAS client to use for component id registration (if needed).

namespace hpx

namespace components

Variables

const *default_distribution_policy* **default_layout** = { }
A predefined instance of the default *distribution_policy*. It will represent the local locality and will place all items to create here.

struct default_distribution_policy
#include <default_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

constexpr default_distribution_policy()
Default-construct a new instance of a default_distribution_policy. This policy will represent one locality (the local locality).

default_distribution_policy **operator()**(*std*::vector<*id_type*> **const** &*locs*) **const**
Create a new *default_distribution* policy representing the given set of localities.

Parameters
- `locs`: [in] The list of localities the new instance should represent

default_distribution_policy **operator()**(*std*::vector<*id_type*> &&*locs*) **const**
Create a new *default_distribution* policy representing the given set of localities.

Parameters
- `locs`: [in] The list of localities the new instance should represent

default_distribution_policy **operator()**(*id_type* **const** &*loc*) **const**
Create a new *default_distribution* policy representing the given locality

Parameters
- `loc`: [in] The locality the new instance should represent

template<typename **Component**, typename ...**Ts**>

hpx::future<*hpx*::*id_type*> **create**(*Ts*&&... *vs*) **const**

Create one object on one of the localities associated by this policy instance

Note This function is part of the placement policy implemented by this class

Return A future holding the global address which represents the newly created object

Parameters

- `vs`: [in] The arguments which will be forwarded to the constructor of the new object.

template<typename **Component**, typename ...**Ts**>
hpx::future<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t *count*, *Ts*&&... *vs*) **const**

Create multiple objects on the localities associated by this policy instance

Note This function is part of the placement policy implemented by this class

Return A future holding the list of global addresses which represent the newly created objects

Parameters

- `count`: [in] The number of objects to create
- `vs`: [in] The arguments which will be forwarded to the constructors of the new objects.

template<typename **Action**, typename ...**Ts**>
async_result<*Action*>::*type* **async**(*launch policy*, *Ts*&&... *vs*) **const**

template<typename **Action**, typename **Callback**, typename ...**Ts**>
async_result<*Action*>::*type* **async_cb**(*launch policy*, *Callback* &&*cb*, *Ts*&&... *vs*) **const**

Note This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Continuation**, typename ...**Ts**>
bool **apply**(*Continuation* &&*c*, *threads*::*thread_priority priority*, *Ts*&&... *vs*) **const**

Note This function is part of the invocation policy implemented by this class

template<typename **Action**, typename ...**Ts**>
bool **apply**(*threads*::*thread_priority priority*, *Ts*&&... *vs*) **const**

template<typename **Action**, typename **Continuation**, typename **Callback**, typename ...**Ts**>
bool **apply_cb**(*Continuation* &&*c*, *threads*::*thread_priority priority*, *Callback* &&*cb*, *Ts*&&... *vs*) **const**

Note This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Callback**, typename ...**Ts**>
bool **apply_cb**(*threads*::*thread_priority priority*, *Callback* &&*cb*, *Ts*&&... *vs*) **const**

std::size_t **get_num_localities**() **const**

Returns the number of associated localities for this distribution policy

Note This function is part of the creation policy implemented by this class

hpx::*id_type* **get_next_target**() **const**

Returns the locality which is anticipated to be used for the next async operation

template<typename **Action**>
struct async_result

#include <default_distribution_policy.hpp>

Note This function is part of the invocation policy implemented by this class

namespace hpx

Functions

template<typename Component, typename... Ts><unspecified> hpx::new_(id_type const & lo
Create one or more new instances of the given Component type on the specified locality.

This function creates one or more new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::new_<some_component>(hpx::find_here(), ...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

Parameters

- `locality`: [in] The global address of the locality where the new instance should be created on.
- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

template<typename Component, typename... Ts><unspecified> hpx::local_new(Ts &&... vs)
Create one new instance of the given Component type on the current locality.

This function creates one new instance of the given Component type on the current locality and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::local_new<some_component>(...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which can be used to retrieve the global address of the newly created component. If the first argument is `hpx::launch::sync` the function will directly return an `hpx::id_type`.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

Note The difference of this function to *hpx::new_* is that it can be used in cases where the supplied arguments are non-copyable and non-movable. All operations are guaranteed to be local only.

Parameters

- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

template<typename Component, typename... Ts><unspecified> hpx::new_(id_type const & lo

Create multiple new instances of the given Component type on the specified locality.

This function creates multiple new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type> > f =
   hpx::new_<some_component[]>(hpx::find_here(), 10, ...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component*[], where `traits::is_component<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component*[], where `traits::is_client<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

Parameters

- `locality`: [in] The global address of the locality where the new instance should be created on.
- `count`: [in] The number of component instances to create

- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

template<typename Component, typename DistPolicy, typename... Ts><unspecified> hpx::ne

Create one or more new instances of the given Component type based on the given distribution policy.

This function creates one or more new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for global address which can be used to reference the new component instance(s).

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::new_<some_component>(hpx::default_layout, ...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

Parameters

- `policy`: [in] The distribution policy used to decide where to place the newly created.
- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

template<typename Component, typename DistPolicy, typename... Ts><unspecified> hpx::ne

Create multiple new instances of the given Component type on the localities as defined by the given distribution policy.

This function creates multiple new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type> > f =
   hpx::new_<some_component[]>(hpx::default_layout, 10, ...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component*[], where `traits::is_component<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.

- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component*[], where `traits::is_client<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

Parameters

- `policy`: [in] The distribution policy used to decide where to place the newly created.
- `count`: [in] The number of component instances to create
- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

runtime_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

class runtime_distributed : **public** *runtime*

#include <runtime_distributed.hpp> The *runtime* class encapsulates the HPX runtime system in a simple to use way. It makes sure all required parts of the HPX runtime system are properly initialized.

Public Functions

hpx::runtime_distributed::runtime_distributed(util::runtime_configuration & rtcfg,

Construct a new HPX runtime instance

Parameters

- `locality_mode`: [in] This is the mode the given runtime instance should be executed in.

~runtime_distributed()

The destructor makes sure all HPX runtime services are properly shut down before exiting.

int **start**(*hpx*::function<hpx_main_function_type> **const** &*func*, bool *blocking* = false)

Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

Parameters

- `func`: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*.
- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally.

int **start**(bool *blocking* = false)

Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

Parameters

- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally .

int **wait**()
Wait for the shutdown action to be executed.

Return This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

void **stop**(bool *blocking* = true)
Initiate termination of the runtime system.

Parameters
- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

int **finalize**(double *shutdown_timeout*)

void **stop_helper**(bool *blocking*, *std*::condition_variable &*cond*, *std*::mutex &*mtx*)
Stop the runtime system, wait for termination.

Parameters
- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

int **suspend**()
Suspend the runtime system.

int **resume**()
Resume the runtime system.

bool **report_error**(*std*::size_t *num_thread*, *std*::exception_ptr **const** &*e*, bool *terminate_all* = true)
Report a non-recoverable error to the runtime system.

Parameters
- `num_thread`: [in] The number of the operating system thread the error has been detected in.
- `e`: [in] This is an instance encapsulating an exception which lead to this function call.
- `terminate_all`: [in] Kill all localities attached to the currently running application (default: true)

bool **report_error**(*std*::exception_ptr **const** &*e*, bool *terminate_all* = true)
Report a non-recoverable error to the runtime system.

Note This function will retrieve the number of the current shepherd thread and forward to the report_error function above.
Parameters
- `e`: [in] This is an instance encapsulating an exception which lead to this function call.

- `terminate_all`: [in] Kill all localities attached to the currently running application (default: true)

int **run**(*hpx*::function<hpx_main_function_type> **const** &*func*)

Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

Note The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

Return This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

Parameters

- `func`: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

int **run**()

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

Return This function will always return 0 (zero).

bool **is_networking_enabled**()

template<typename **F**>
components::*server*::*console_error_dispatcher*::*sink_type* **set_error_sink**(*F* &&*sink*)

performance_counters::*registry* &**get_counter_registry**()

Allow access to the registry counter registry instance used by the HPX runtime.

performance_counters::*registry* **const** &**get_counter_registry**() **const**

Allow access to the registry counter registry instance used by the HPX runtime.

void **register_counter_types**()

Install all performance counters related to this runtime instance.

void **register_query_counters**(*std*::shared_ptr<*util*::*query_counters*> **const** &*active_counters*)

void **start_active_counters**(*error_code* &*ec* = *throws*)

void **stop_active_counters**(*error_code* &*ec* = *throws*)

void **stop_evaluating_counters**(bool *terminate* = false)

naming::*resolver_client* &**get_agas_client**()

Allow access to the AGAS client instance used by the HPX runtime.

hpx::*threads*::*threadmanager* &**get_thread_manager**()
Allow access to the thread manager instance used by the HPX runtime.

applier::*applier* &**get_applier**()
Allow access to the applier instance used by the HPX runtime.

std::string **here**() **const**
Returns a string of the locality endpoints (usable in debug output)

naming::*address_type* **get_runtime_support_lva**() **const**

naming::*gid_type* **get_next_id**(*std*::size_t *count* = 1)

void **init_id_pool_range**()

util::*unique_id_ranges* &**get_id_pool**()

void **initialize_agas**()
Initialize AGAS operation.

void **add_pre_startup_function**(*startup_function_type f*)
Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with *add_startup_function*.

Note The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

Parameters

- `f`: The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void **add_startup_function**(*startup_function_type f*)
Add a function to be executed inside a HPX thread before hpx_main

Parameters

- `f`: The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void **add_pre_shutdown_function**(*shutdown_function_type f*)
Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

Note The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

Parameters

- `f`: The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

void **add_shutdown_function**(*shutdown_function_type f*)
Add a function to be executed inside a HPX thread during hpx::finalize

Parameters

- `f`: The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

hpx::*util*::*io_service_pool* ***get_thread_pool**(char **const** *name*)

Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are "main_pool", "io_pool", "parcel_pool", and "timer_pool". For any other argument value the function will return zero.

bool **register_thread**(char **const** *name*, *std*::size_t *num* = 0, bool *service_thread* = true, *error_code* &*ec* = *throws*)

Register an external OS-thread with HPX.

notification_policy_type **get_notification_policy**(char **const** *prefix*, *runtime_local*::*os_thread_type type*)

Generate a new notification policy instance for the given thread name prefix

std::uint32_t **get_locality_id**(*error_code* &*ec*) **const**

std::size_t **get_num_worker_threads**() **const**

namespace hpx

namespace applier

class applier

#include <applier.hpp> The *applier* class is used to decide whether a particular action has to be issued on a local or a remote resource. If the target component is local a new *thread* will be created, if the target is remote a parcel will be sent.

Public Functions

HPX_NON_COPYABLE(*applier*)

applier()

void **init**(*threads*::*threadmanager* &*tm*)

~applier()

void **initialize**(*std*::uint64_t *rts*)

threads::*threadmanager* &**get_thread_manager**()

Access the *thread-manager* instance associated with this *applier*.

This function returns a reference to the thread manager this applier instance has been created with.

naming::*gid_type* **const** &**get_raw_locality**(*error_code &ec = throws*) **const**
Allow access to the locality of the locality this applier instance is associated with.

This function returns a reference to the locality this applier instance is associated with.

std::uint32_t **get_locality_id**(*error_code &ec = throws*) **const**
Allow access to the id of the locality this applier instance is associated with.

This function returns a reference to the id of the locality this applier instance is associated with.

bool **get_raw_remote_localities**(*std*::vector<*naming*::*gid_type*> *&locality_ids*, *components*::*component_type type = components*::*component_invalid*, *error_code &ec = throws*) **const**
Return list of localities of all remote localities registered with the AGAS service for a specific component type.

This function returns a list of all remote localities (all localities known to AGAS except the local one) supporting the given component type.

Return The function returns *true* if there is at least one remote locality known to the AGASservice (!prefixes.empty()).
Parameters
- `locality_ids`: [out] The reference to a vector of id_types filled by the function.
- `type`: [in] The type of the component which needs to exist on the returned localities.

bool **get_remote_localities**(*std*::vector<*hpx*::*id_type*> *&locality_ids*, *components*::*component_type type = components*::*component_invalid*, *error_code &ec = throws*) **const**

bool **get_raw_localities**(*std*::vector<*naming*::*gid_type*> *&locality_ids*, *components*::*component_type type = components*::*component_invalid*) **const**
Return list of locality_ids of all localities registered with the AGAS service for a specific component type.

This function returns a list of all localities (all localities known to AGAS except the local one) supporting the given component type.

Return The function returns *true* if there is at least one remote locality known to the AGASservice (!prefixes.empty()).
Parameters
- `locality_ids`: [out] The reference to a vector of id_types filled by the function.
- `type`: [in] The type of the component which needs to exist on the returned localities.

bool **get_localities**(*std*::vector<*hpx*::*id_type*> *&locality_ids*, *error_code &ec = throws*) **const**

bool **get_localities**(*std*::vector<*hpx*::*id_type*> *&locality_ids*, *components*::*component_type type*, *error_code &ec = throws*) **const**

naming::*gid_type* **const** &**get_runtime_support_raw_gid**() **const**
By convention the runtime_support has a gid identical to the prefix of the locality the runtime_support is responsible for

hpx::*id_type* **const** &**get_runtime_support_gid**() **const**
By convention the runtime_support has a gid identical to the prefix of the locality the runtime_support is responsible for

Private Members

threads::*threadmanager* ***thread_manager_**

hpx::*id_type* **runtime_support_id_**

namespace hpx

namespace applier

Functions

applier &**get_applier**()
The function *get_applier* returns a reference to the (thread specific) applier instance.

applier ***get_applier_ptr**()
The function *get_applier* returns a pointer to the (thread specific) applier instance. The returned pointer is NULL if the current thread is not known to HPX or if the runtime system is not active.

namespace applier
The namespace *applier* contains all definitions needed for the class hpx::applier::applier and its related functionality. This namespace is part of the HPX core module.

namespace hpx

namespace components

Functions

template<typename **Component**>
future<*hpx*::*id_type*> **copy**(*hpx*::*id_type* **const** &*to_copy*)
Copy given component to the specified target locality.

The function *copy*<*Component*> will create a copy of the component referenced by *to_copy* on the locality specified with *target_locality*. It returns a future referring to the newly created component instance.

Return A future representing the global id of the newly (copied) component instance.
Note The new component instance is created on the locality of the component instance which is to be copied.
Parameters
- `to_copy`: [in] The global id of the component to copy

Template Parameters
- `The`: only template argument specifies the component type to create.

template<typename **Component**>
future<*hpx*::*id_type*> **copy**(*hpx*::*id_type* **const** &*to_copy*, *hpx*::*id_type* **const** &*target_locality*)
Copy given component to the specified target locality.

The function *copy*<*Component*> will create a copy of the component referenced by *to_copy* on the locality specified with *target_locality*. It returns a future referring to the newly created component instance.

Return A future representing the global id of the newly (copied) component instance.

Parameters

- `to_copy`: [in] The global id of the component to copy
- `target_locality`: [in] The locality where the copy should be created.

Template Parameters

- `The`: only template argument specifies the component type to create.

template<typename **Derived**, typename **Stub**>
Derived **copy** (client_base<*Derived*, *Stub*> **const** &*to_copy*, *hpx*::*id_type* **const** &*target_locality* = *hpx*::*invalid_id*)

Copy given component to the specified target locality.

The function *copy* will create a copy of the component referenced by the client side object *to_copy* on the locality specified with *target_locality*. It returns a new client side object future referring to the newly created component instance.

Return A future representing the global id of the newly (copied) component instance.

Note If the second argument is omitted (or is invalid_id) the new component instance is created on the locality of the component instance which is to be copied.

Parameters

- `to_copy`: [in] The client side object representing the component to copy
- `target_locality`: [in, optional] The locality where the copy should be created (default is same locality as source).

Template Parameters

- `The`: only template argument specifies the component type to create.

namespace hpx

Functions

hpx::*id_type* **find_root_locality** (*error_code* &*ec* = *throws*)

Return the global id representing the root locality.

The function find_root_locality() can be used to retrieve the global id usable to refer to the root locality. The root locality is the locality where the main AGAS service is hosted.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global id representing the root locality for this application.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

See hpx::find_all_localities(), hpx::find_locality()

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::vector<*hpx*::*id_type*> **find_all_localities** (*error_code* &*ec* = *throws*)

Return the list of global ids representing all localities available to this application.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global ids representing the localities currently available to this application.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

See hpx::find_here(), hpx::find_locality()

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::vector<*hpx*::*id_type*> **`find_remote_localities`**(*error_code* &*ec* = *throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one).

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global ids representing the remote localities currently available to this application.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

See hpx::find_here(), hpx::find_locality()

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

`namespace hpx`

Functions

hpx::*id_type* **`find_here`**(*error_code* &*ec* = *throws*)

Return the global id representing this locality.

The function find_here() can be used to retrieve the global id usable to refer to the current locality.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global id representing the locality this function has been called on.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

See hpx::find_all_localities(), hpx::find_locality()

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

namespace hpx

Functions

std::vector<*hpx*::*id_type*> **find_all_localities**(*components*::*component_type type*, *error_code &ec = throws*)

Return the list of global ids representing all localities available to this application which support the given component type.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application which support the creation of instances of the given component type.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global ids representing the localities currently available to this application which support the creation of instances of the given component type. If no localities supporting the given component type are currently available, this function will return an empty vector.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

See hpx::find_here(), hpx::find_locality()

Parameters

- `type`: [in] The type of the components for which the function should return the available localities.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::vector<*hpx*::*id_type*> **find_remote_localities**(*components*::*component_type type*, *error_code &ec = throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one) which support the creation of instances of the given component type.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global ids representing the remote localities currently available to this application.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

See hpx::find_here(), hpx::find_locality()

Parameters

- `type`: [in] The type of the components for which the function should return the available remote localities.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*id_type* **`find_locality`**(*components*::*component_type type*, *error_code* &*ec* = *throws*)

Return the global id representing an arbitrary locality which supports the given component type.

The function find_locality() can be used to retrieve the global id of an arbitrary locality currently available to this application which supports the creation of instances of the given component type.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global id representing an arbitrary locality currently available to this application which supports the creation of instances of the given component type. If no locality supporting the given component type is currently available, this function will return *hpx::invalid_id*.

Note As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

See hpx::find_here(), hpx::find_all_localities()

Parameters

- `type`: [in] The type of the components for which the function should return any available locality.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

`namespace hpx`

Functions

future<*std*::string> **get_locality_name**(*hpx*::*id_type* **const** &*id*)

Return the name of the referenced locality.

This function returns a future referring to the name for the locality of the given id.

Return This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

See *std::string get_locality_name()*

Parameters

- `id`: [in] The global id of the locality for which the name should be retrieved

namespace hpx

Functions

hpx::future<*std*::uint32_t> **get_num_localities**(*components*::*component_type t*)

Asynchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See *hpx::find_all_localities*, *hpx::get_num_localities*

Parameters

- `t`: The component type for which the number of connected localities should be retrieved.

std::uint32_t **get_num_localities**(*launch*::sync_policy, *components*::*component_type t*, *error_code* &*ec* = *throws*)

Synchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See *hpx::find_all_localities*, *hpx::get_num_localities*

Parameters

- `t`: The component type for which the number of connected localities should be retrieved.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

namespace hpx

namespace components

Functions

template<typename **Component**, typename **DistPolicy**>
future<*hpx*::*id_type*> **migrate** (*hpx*::*id_type* **const** &*to_migrate*, *DistPolicy* **const** &*policy*)

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `policy`: [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- `Component`: Specifies the component type of the component to migrate.
- `DistPolicy`: Specifies the distribution policy to use to determine the destination locality.

template<typename **Derived**, typename **Stub**, typename **DistPolicy**>
Derived **migrate** (client_base<*Derived*, *Stub*> **const** &*to_migrate*, *DistPolicy* **const** &*policy*)

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `policy`: [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- `Derived`: Specifies the component type of the component to migrate.
- `DistPolicy`: Specifies the distribution policy to use to determine the destination locality.

template<typename **Component**>
future<*hpx*::*id_type*> **migrate** (*hpx*::*id_type* **const** &*to_migrate*, *hpx*::*id_type* **const** &*target_locality*)

Migrate the component with the given id to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

Parameters

- `to_migrate`: [in] The global id of the component to migrate.
- `target_locality`: [in] The locality where the component should be migrated to.

Template Parameters

- `Component`: Specifies the component type of the component to migrate.

template<typename **Derived**, typename **Stub**>
Derived **migrate** (client_base<*Derived*, *Stub*> **const** &*to_migrate*, *hpx*::*id_type* **const** &*target_locality*)

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Return A client side representation of representing of the migrated component instance. This should be the same as *migrate_to*.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `target_locality`: [in] The id of the locality to migrate this object to.

Template Parameters

- `Derived`: Specifies the component type of the component to migrate.

Public Members

hpx::components::server::runtime_support::terminate_all_act

Public Static Functions

static *component_type* **get_component_type**()

static void **set_component_type**(*component_type t*)

static constexpr void **finalize**()
finalize() will be called just before the instance gets destructed

Parameters
- `self`: [in] The HPX *thread* used to execute this function.
- `appl`: [in] The applier to be used for finalization of the component instance.

static bool **is_target_valid**(*hpx*::*id_type* **const** &*id*)

Public Static Functions

template<typename **Component**, typename ...**Ts**>
static *hpx*::future<*hpx*::*id_type*> **create_component_async**(*hpx*::*id_type* **const** &*gid*, *Ts*&&... *vs*)

Create a new component *type* using the *runtime_support* with the given *targetgid*. This is a non-blocking call. The caller needs to call *future::get* on the result of this function to obtain the global id of the newly created object.

template<typename **Component**, typename ...**Ts**>
static *hpx*::*id_type* **create_component**(*hpx*::*id_type* **const** &*gid*, *Ts*&&... *vs*)

Create a new component *type* using the *runtime_support* with the given *targetgid*. Block for the creation to finish.

template<typename **Component**, typename ...**Ts**>
static *hpx*::future<*std*::vector<*hpx*::*id_type*>> **bulk_create_component_colocated_async**(*hpx*::*id_* **const** &*gid*, *std*::size *count*, *Ts*&&... *vs*)

Create multiple new components *type* using the *runtime_support* colocated with the with the given *targetgid*. This is a non-blocking call.

template<typename **Component**, typename ...**Ts**>
static *std*::vector<*hpx*::*id_type*> **bulk_create_component_colocated**(*hpx*::*id_type* **const** &*gid*, *std*::size_t *count*, *Ts*&&... *vs*)

Create multiple new components *type* using the *runtime_support* colocated with the with the given *targetgid*. Block for the creation to finish.

template<typename **Component**, typename ...**Ts**>
static *hpx*::future<*std*::vector<*hpx*::*id_type*>> **bulk_create_component_async**(*hpx*::*id_type* **const** &*gid*, *std*::size_t *count*, *Ts*&&... *vs*)

Create multiple new components *type* using the *runtime_support* on the given locality. This is a non-blocking call.

template<typename **Component**, typename ...**Ts**>
static *std*::vector<*hpx*::*id_type*> **bulk_create_component**(*hpx*::*id_type* **const** &*gid*, *std*::size_t *count*, *Ts*&&... *vs*)

Create multiple new components *type* using the *runtime_support* on the given locality. Block for the creation to finish.

template<typename **Component**, typename ...**Ts**>

static *hpx*::future<*hpx*::*id_type*> **create_component_colocated_async**(*hpx*::*id_type* **const** &*gid*, *Ts*&&... *vs*)

Create a new component *type* using the *runtime_support* with the given *targetgid*. This is a non-blocking call. The caller needs to call *future::get* on the result of this function to obtain the global id of the newly created object.

template<typename **Component**, typename ...**Ts**>
static *hpx*::*id_type* **create_component_colocated**(*hpx*::*id_type* **const** &*gid*, *Ts*&&... *vs*)

Create a new component *type* using the *runtime_support* with the given *targetgid*. Block for the creation to finish.

namespace hpx

namespace components

Functions

template<typename **Component**>
future<*hpx*::*id_type*> **migrate_from_storage**(*hpx*::*id_type* **const** &*to_resurrect*, *hpx*::*id_type* **const** &*target* = *hpx*::*invalid_id*)

Migrate the component with the given id from the specified target storage (resurrect the object)

The function *migrate_from_storage<Component>* will migrate the component referenced by *to_resurrect* from the storage facility specified where the object is currently stored on. It returns a future referring to the migrated component instance. The component instance is resurrected on the locality specified by *target_locality*.

Return A future representing the global id of the migrated component instance. This should be the same as *to_resurrect*.

Parameters

- `to_resurrect`: [in] The global id of the component to migrate.
- `target`: [in] The optional locality to resurrect the object on. By default the object is resurrected on the locality it was located on last.

Template Parameters

- `The`: only template argument specifies the component type of the component to migrate from the given storage facility.

template<typename **Component**>
future<*hpx*::*id_type*> **migrate_to_storage**(*hpx*::*id_type* **const** &*to_migrate*, *hpx*::*id_type* **const** &*target_storage*)

Migrate the component with the given id to the specified target storage

The function *migrate_to_storage<Component>* will migrate the component referenced by *to_migrate* to the storage facility specified with *target_storage*. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

Parameters

- `to_migrate`: [in] The global id of the component to migrate.
- `target_storage`: [in] The id of the storage facility to migrate this object to.

Template Parameters

- `The`: only template argument specifies the component type of the component to migrate to the given storage facility.

template<typename **Derived**, typename **Stub**>
Derived **migrate_to_storage**(client_base<*Derived*, *Stub*> **const** &*to_migrate*, *hpx*::*components*::component_storage **const** &*target_storage*)

Migrate the given component to the specified target storage

The function *migrate_to_storage* will migrate the component referenced by *to_migrate* to the storage facility specified with *target_storage*. It returns a future referring to the migrated component instance.

Return A client side representation of representing of the migrated component instance. This should be the same as *migrate_to*.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `target_storage`: [in] The id of the storage facility to migrate this object to.

2.9 Contributing to *HPX*

HPX development happens on Github. The following sections are a collection of useful information related to *HPX* development.

2.9.1 Contributing to *HPX*

The main source of information to understand the process of how to contribute to HPX can be found in this document[467]. This is a living document that is constantly updated with relevant information.

2.9.2 *HPX* governance model

The *HPX* project is a meritocratic, consensus-based community project. Anyone with an interest in the project can join the community, contribute to the project design and participate in the decision making process. This document[468] describes how that participation takes place and how to set about earning merit within the project community.

2.9.3 Release procedure for *HPX*

Below is a step by step procedure for making an *HPX* release. We aim to produce two releases per year: one in March-April, and one in September-October.

This is a living document and may not be totally current or accurate. It is an attempt to capture current practices in making an *HPX* release. Please update it as appropriate.

One way to use this procedure is to print a copy and check off the lines as they are completed to avoid confusion.

1. Notify developers that a release is imminent.
2. For minor and major releases: create and check out a new branch at an appropriate point on `master` with the name `release-major.minor.X`. `major` and `minor` should be the major and minor versions of the release. For patch releases: check out the corresponding `release-major.minor.X` branch.
3. Write release notes in `docs/sphinx/releases/whats_new_$VERSION.rst`. Keep adding merged PRs and closed issues to this until just before the release is made. Use `tools/generate_pr_issue_list.sh` to generate the lists. Add the new release notes to the table of contents in `docs/sphinx/releases.rst`.
4. Build the docs, and proof-read them. Update any documentation that may have changed, and correct any typos. Pay special attention to:
   - `$HPX_SOURCE/README.rst`
     - Update grant information
   - `docs/sphinx/releases/whats_new_$VERSION.rst`
   - `docs/sphinx/about_hpx/people.rst`
     - Update collaborators
     - Update grant information
5. This step does not apply to patch releases. For both APEX and libCDS:
   - Change the release branch to be the most current release tag available in the APEX/libCDS `git_external` section in the main `CMakeLists.txt`. Please contact the maintainers of the respective packages to generate a new release to synchronize with the *HPX* release (APEX[469], libCDS[470]).
6. Make sure `HPX_VERSION_MAJOR/MINOR/SUBMINOR` in `CMakeLists.txt` contain the correct values. Change them if needed.

[467] https://github.com/STEllAR-GROUP/hpx/blob/master/.github/CONTRIBUTING.md
[468] http://hpx.stellar-group.org/documents/governance/
[469] http://github.com/UO-OACISS/xpress-apex
[470] https://github.com/STEllAR-GROUP/libcds

7. This step does not apply to patch releases. Remove features which have been deprecated for at least 2 releases. This involves removing build options which enable those features from the main CMakeLists.txt and also deleting all related code and tests from the main source tree.

   The general deprecation policy involves a three-step process we have to go through in order to introduce a breaking change:

   a. First release cycle: add a build option that allows for explicitly disabling any old (now deprecated) code.

   b. Second release cycle: turn this build option OFF by default.

   c. Third release cycle: completely remove the old code.

   The main CMakeLists.txt contains a comment indicating for which version the breaking change was introduced first. In the case of deprecated features which don't have a replacement yet, we keep them around in case (like Vc for example).

8. Update the minimum required versions if necessary (compilers, dependencies, etc.) in `building_hpx.rst`.

9. Verify that the Jenkins setups for the release branch on Rostam and Piz Daint are running and do not display any errors.

10. Repeat the following steps until satisfied with the release.

    1. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to `-rcN`, where `N` is the current iteration of this step. Start with `-rc1`.

    2. Create a pre-release on GitHub using the script `tools/roll_release.sh`. This script automatically tag with the corresponding release number. The script requires that you have the STE||AR Group signing key.

    3. This step is not necessary for patch releases. Notify `hpx-users@stellar-group.org` and `stellar@cct.lsu.edu` of the availability of the release candidate. Ask users to test the candidate by checking out the release candidate tag.

    4. Allow at least a week for testing of the release candidate.

       - Use `git merge` when possible, and fall back to `git cherry-pick` when needed. For patch releases `git cherry-pick` is most likely your only choice if there have been significant unrelated changes on master since the previous release.

       - Go back to the first step when enough patches have been added.

       - If there are no more patches, continue to make the final release.

11. Update any occurrences of the latest stable release to refer to the version about to be released. For example, `quickstart.rst` contains instructions to check out the latest stable tag. Make sure that refers to the new version.

12. Add a new entry to the RPM changelog (`cmake/packaging/rpm/Changelog.txt`) with the new version number and a link to the corresponding changelog.

13. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to an empty string.

14. Add the release date to the caption of the current "What's New" section in the docs, and change the value of `HPX_VERSION_DATE` in `CMakeLists.txt`.

15. Create a release on GitHub using the script `tools/roll_release.sh`. This script automatically tag the with the corresponding release number. The script requires that you have the STE||AR Group signing key.

16. Update the websites (hpx.stellar-group.org[471], stellar-group.org[472] and stellar.cct.lsu.edu[473]). You can login on

[471] https://hpx.stellar-group.org
[472] https://stellar-group.org
[473] https://stellar.cct.lsu.edu

wordpress through *this page <https://hpx.stellar-group.org/wp-login.php>*. You can update the pages with the following:

- Update links on the downloads page. Link to the release on GitHub.
- Documentation links on the docs page (link to generated documentation on GitHub Pages). Follow the style of previous releases.
- A new blog post announcing the release, which links to downloads and the "What's New" section in the documentation (see previous releases for examples).

17. Merge release branch into master.
18. Post-release cleanup. Create a new pull request against master with the following changes:
    1. Modify the release procedure if necessary.
    2. Change `HPX_VERSION_TAG` in `CMakeLists.txt` back to `-trunk`.
    3. Increment `HPX_VERSION_MINOR` in `CMakeLists.txt`.
19. Update Vcpkg (`https://github.com/Microsoft/vcpkg`) to pull from latest release.
    - Update version number in CONTROL
    - Update tag and SHA512 to that of the new release
20. Update spack (`https://github.com/spack/spack`) with the latest HPX package.
    - Update version number in `hpx/package.py` and SHA256 to that of the new release
21. Announce the release on hpx-users@stellar-group.org, stellar@cct.lsu.edu, allcct@cct.lsu.edu, faculty@csc.lsu.edu, faculty@ece.lsu.edu, xpress@crest.iu.edu, the *HPX* Slack channel, the IRC channel, Sonia Sachs, our list of external collaborators, isocpp.org, reddit.com, HPC Wire, Inside HPC, Heise Online, and a CCT press release.
22. Beer and pizza.

2.9.4 Testing *HPX*

To ensure correctness of *HPX*, we ship a large variety of unit and regression tests. The tests are driven by the CTest[474] tool and are executed automatically on each commit to the *HPX* Github[475] repository. In addition, it is encouraged to run the test suite manually to ensure proper operation on your target system. If a test fails for your platform, we highly recommend submitting an issue on our *HPX* Issues[476] tracker with detailed information about the target system.

Running tests manually

Running the tests manually is as easy as typing `make tests && make test`. This will build all tests and run them once the tests are built successfully. After the tests have been built, you can invoke separate tests with the help of the `ctest` command. You can list all available test targets using `make help | grep tests`. Please see the CTest Documentation[477] for further details.

[474] https://gitlab.kitware.com/cmake/community/wikis/doc/ctest/Testing-With-CTest
[475] https://github.com/STEllAR-GROUP/hpx/
[476] https://github.com/STEllAR-GROUP/hpx/issues
[477] https://www.cmake.org/cmake/help/latest/manual/ctest.1.html

Running performance tests

We run performance tests on Piz Daint for each pull request using Jenkins. To run those performance tests locally or on Piz Daint, a script is provided under `tools/perftests_ci/local_run.sh` (to be run in the build directory specifying the *HPX* source directory as the argument to the script, default is `$HOME/projects/hpx_perftests_ci`.

Adding new performance tests

To add a new performance test, you need to wrap the portion of code to benchmark with `hpx::util::perftests_report`, passing the test name, the executor name and the function to time (can be a lambda). This facility is used to output the time results in a json format (format needed to compare the results and plot them). To effectively print them at the end of your test, call `hpx::util::perftests_print_times`. To see an example of use, see `future_overhead_report.cpp`. Finally, you can add the test to the CI report editing the `hpx_targets` variable for the executable name and the `hpx_test_options` variable for the corresponding options to use for the run in the performance test script `.jenkins/cscs-perftests/launch_perftests.sh`. And then run the `tools/perftests_ci/local_run.sh` script to get a reference json run (use the name of the test) to be added in the `tools/perftests_ci/perftest/references/daint_default` directory.

Issue tracker

If you stumble over a bug or missing feature in *HPX*, please submit an issue to our *HPX* Issues[478] page. For more information on how to submit support requests or other means of getting in contact with the developers, please see the Support Website[479] page.

Continuous testing

In addition to manual testing, we run automated tests on various platforms. We also run tests on all pull requests using both CircleCI[480] and a combination of CDash[481] and pycicle[482]. You can see the dashboards here: CircleCI HPX dashboard[483] and CDash HPX dashboard[484] .

2.9.5 Using docker for development

Although it can often be useful to set up a local development environment with system-provided or self-built dependencies, Docker[485] provides a convenient alternative to quickly get all the dependencies needed to start development of *HPX*. Our testing setup on CircleCI[486] uses a docker image to run all tests.

To get started you need to install Docker[487] using whatever means is most convenient on your system. Once you have Docker[488] installed, you can pull or directly run the docker image. The image is based on Debian and Clang, and can be found on Docker Hub[489]. To start a container using the *HPX* build environment, run:

[478] https://github.com/STEllAR-GROUP/hpx/issues
[479] https://stellar.cct.lsu.edu/support/
[480] https://circleci.com
[481] https://www.kitware.com/cdash/project/about.html
[482] https://github.com/biddisco/pycicle/
[483] https://circleci.com/gh/STEllAR-GROUP/hpx
[484] https://cdash.cscs.ch/index.php?project=HPX
[485] https://www.docker.com
[486] https://circleci.com
[487] https://www.docker.com
[488] https://www.docker.com
[489] https://hub.docker.com/r/stellargroup/build_env/

```
$ docker run --interactive --tty stellargroup/build_env:latest bash
```

You are now in an environment where all the *HPX* build and runtime dependencies are present. You can install additional packages according to your own needs. Please see the Docker Documentation[490] for more information on using Docker[491].

Warning: All changes made within the container are lost when the container is closed. If you want files to persist (e.g., the *HPX* source tree) after closing the container, you can bind directories from the host system into the container (see Docker Documentation (Bind mounts)[492]).

2.9.6 Documentation

This documentation is built using Sphinx[493], and an automatically generated API reference using Doxygen[494] and Breathe[495].

We always welcome suggestions on how to improve our documentation, as well as pull requests with corrections and additions.

Prerequisites

To build the *HPX* documentation, you need recent versions of the following packages:

- `python3`
- `sphinx 3.5.4` (Python package)
- `sphinx_rtd_theme` (Python package)
- `breathe 4.16.0` (Python package)
- `doxygen`

If the Python[496] dependencies are not available through your system package manager, you can install them using the Python package manager `pip`:

```
pip install --user sphinx sphinx_rtd_theme breathe
```

You may need to set the following CMake variables to make sure CMake can find the required dependencies.

DOXYGEN_ROOT:PATH
Specifies where to look for the installation of the Doxygen[497] tool.

SPHINX_ROOT:PATH
Specifies where to look for the installation of the Sphinx[498] tool.

BREATHE_APIDOC_ROOT:PATH
Specifies where to look for the installation of the Breathe[499] tool.

[496] https://www.python.org
[497] https://www.doxygen.org
[498] http://www.sphinx-doc.org
[499] https://breathe.readthedocs.io/en/latest

Building documentation

Enable building of the documentation by setting `HPX_WITH_DOCUMENTATION=ON` during CMake[500] configuration. To build the documentation, build the `docs` target using your build tool. The default output format is HTML documentation. You can choose alternative output formats (single-page HTML, PDF, and man) with the `HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS` CMake option.

Note: If you add new source files to the Sphinx documentation, you have to run CMake again to have the files included in the build.

Style guide

The documentation is written using reStructuredText. These are the conventions used for formatting the documentation:

- Use, at most, 80 characters per line.
- Top-level headings use over- and underlines with =.
- Sub-headings use only underlines with characters in decreasing level of importance: =, – and `..`
- Use sentence case in headings.
- Refer to common terminology using `:term:`Component``.
- Indent content of directives (`.. directive::`) by three spaces.
- For C++ code samples at the end of paragraphs, use `::` and indent the code sample by 4 spaces.
  - For other languages (or if you don't want a colon at the end of the paragraph), use `.. code-block:: language` and indent by three spaces as with other directives.
- Use `.. list-table::` to wrap tables with a lot of text in cells.

API documentation

The source code is documented using Doxygen. If you add new API documentation either to existing or new source files, make sure that you add the documented source files to the `doxygen_dependencies` variable in `docs/CMakeLists.txt`.

2.9.7 Module structure

This section explains the structure of an *HPX* module.

The tool create_library_skeleton.py[501] can be used to generate a basic skeleton. To create a library skeleton, run the tool in the `libs` subdirectory with the module name as an argument:

```
$ ./create_library_skeleton <lib_name>
```

This creates a skeleton with the necessary files for an *HPX* module. It will not create any actual source files. The structure of this skeleton is as follows:

- `<lib_name>/`

[500] https://www.cmake.org
[501] https://github.com/STEllAR-GROUP/hpx/blob/master/libs/create_library_skeleton.py

```
- README.rst
- CMakeLists.txt
- cmake
- docs/
    * index.rst
- examples/
    * CMakeLists.txt
- include/
    * hpx/
        · <lib_name>
- src/
    * CMakeLists.txt
- tests/
    * CMakeLists.txt
    * unit/
        · CMakeLists.txt
    * regressions/
        · CMakeLists.txt
    * performance/
        · CMakeLists.txt
```

A `README.rst` should be always included which explains the basic purpose of the library and a link to the generated documentation.

A main `CMakeLists.txt` is created in the root directory of the module. By default it contains a call to `add_hpx_module` which takes care of most of the boilerplate required for a module. You only need to fill in the source and header files in most cases.

`add_hpx_module` requires a module name. Optional flags are:

Optional single-value arguments are:

- `INSTALL_BINARIES`: Install the resulting library.

Optional multi-value arguments-are:

- `SOURCES`: List of source files.
- `HEADERS`: List of header files.
- `COMPAT_HEADERS`: List of compatibility header files.
- `DEPENDENCIES`: Libraries that this module depends on, such as other modules.
- `CMAKE_SUBDIRS`: List of subdirectories to add to the module.

The `include` directory should contain only headers that other libraries need. For each of those headers, an automatic header test to check for self containment will be generated. Private headers should be placed under the `src` directory.

This allows for clear separation. The `cmake` subdirectory may include additional CMake[502] scripts needed to generate the respective build configurations.

Compatibility headers (forwarding headers for headers whose location is changed when creating a module, if moving them from the main library) should be placed in an `include_compatibility` directory. This directory is not created by default.

Documentation is placed in the `docs` folder. A empty skeleton for the index is created, which is picked up by the main build system and will be part of the generated documentation. Each header inside the `include` directory will automatically be processed by Doxygen and included into the documentation. If a header should be excluded from the API reference, a comment `// sphinx:undocumented` needs to be added.

Tests are placed in suitable subdirectories of `tests`.

When in doubt, consult existing modules for examples on how to structure the module.

Finding circular dependencies

Our CI will perform a check to see if there are circular dependencies between modules. In cases where it's not clear what is causing the circular dependency, running the cpp-dependencies[503] tool manually can be helpful. It can give you detailed information on exactly which files are causing the circular dependency. If you do not have the `cpp-dependencies` tool already installed, one way of obtaining it is by using our docker image. This way you will have exactly the same environment as on the CI. See *Using docker for development* for details on how to use the docker image.

To produce the graph produced by CI run the following command (`HPX_SOURCE` is assumed to hold the path to the *HPX* source directory):

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --graph-cycles circular_dependencies.dot
```

This will produce a `dot` file in the current directory. You can inspect this manually with a text editor. You can also convert this to an image if you have `graphviz` installed:

```
$ dot circular_dependencies.dot -Tsvg -o circular_dependencies.svg
```

This produces an `svg` file in the current directory which shows the circular dependencies. Note that if there are no cycles the image will be empty.

You can use `cpp-dependencies` to print the include paths between two modules.

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --shortest <from> <to>
```

prints all possible paths from the module `<from>` to the module `<to>`. For example, as most modules depend on `config`, the following should give you a long list of paths from `algorithms` to `config`:

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --shortest algorithms config
```

The following should report that it can't find a path between the two modules:

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --shortest config algorithms
```

2.10 Releases

2.10.1 *HPX* V1.8.0 (Feb 15, 2022)

With HPX parallel algorithms been fully adapted in C++20 the new release achieves full conformance with C++20 concurrency and parallelism facilities. Much work has been done towards implementing P2300 ("std::execution") and implementing the underlying senders/receivers facilities. Finally, The new release comes with a brand new documentation interface!

General changes

- With the new vectorization registers introduced in recent hardware arhcitectures HPX now provides new data-parallel vector types that record significant speed-up using Single Instruction Multiple Data execution policies. The following datapar algorithms now support SIMD execution.: - `copy`, - `generate`, - `adjacent_difference`, - `all_of`, - `any_of`, - `none_of`, - `mismatch`, - `adjacent_find`, - `find`, - `find_end`, - `find_first_of`, - `find_if`, - `find_if_not`.
- The new documentation can now be found on our webpage: https://hpx-docs.stellar-group.org. This includes a completely new and user-friendly interface environment along with restructuring of certain components. The content in the "Quick start", "Manual" and "Examples" was improved, while the "Build system" page was adapted to include necessary information for newcommers.
- Based on top of [P2300](wg21.link/p2300) the HPX parallel algorithms now support the pipeline syntax towards an effort to unify their usage along with senders/receivers. The HPX parallel algorithms can now bind with senders/receivers using the pipeline operator.
- Several changes took place on the executors provided by HPX:
- The executors now support the `num_cores` options in order for the user to be able to specify the desired number of cores to be used in the correspodning execution.
- The `scheduler` executor was implemented on top of senders/receivers and can be used with all HPX facilities that schedule new work, such as parallel algorithms, hpx::async, hpx::dataflow, etc.
- The performance of `fork_join_executor` was improved.
- The following algorithms have been added/adapted to be C++20 conformant:
  - `min_element`,
  - `max_element`,
  - `minmax_element`,
  - `starts_with`,
  - `ends_with`,
  - `swap_ranges`,
  - `unique`,
  - `unique_copy`,
  - `rotate`,
  - `rotate_copy`,
  - `sort`,
  - `shift_left`,

  - shift_right,
  - stable_sort,
  - partition,
  - partition_copy,
  - stable_partition,
  - adjacent_difference,
  - nth_element,
  - partial_sort,
  - partial_sort_copy.
- The following CMake flags were added: HPX_SERIALIZATION_WITH_ALLOW_RAW_POINTER_SERIALIZATION.
- HPX_FORWARD/HPX_MOVE macros were introduced and replaced the std::move and std::forward facilities.
- Hangs on distributed barrier were fixed.
- The performance of scan_partitioner was improved.
- Regarding senders/receivers and the P2300 proposal various actions took place. Support was added for thread_priority to the parallel_execution_policy .``stop_token`` was adapted to the recent proposal version. Also hint, annotation, priority and stacksize properties were added to the scheduler executor. Stop support was added to when_all. Support for completion signatures was added. The following schedulers and algorithms were added: - get_completion_scheduler. - any_sender/unique_any_sender. - split sender. - transform_mpi sender. - transfer sender.
- Several namespaces were altered towards conformance with C++20. Compatibility layers have been added and the old versions will be removed in next releases. The namespace changes are the following: - hpx::parallel::induction/reduction were movied into namespace hpx::experimental - for_loop and friends were moved into namespace hpx::experimental. - hpx::util::optional and friends were moved into namespace hpx. - hpx::lcos::barrier has been moved into the hpx::distributed namespace and

    hpx::lcos::local::cpp20_barrier has been ranamed to barrier and moved into the hpx namespace.

  - hpx::lcos::latch has been moved into the hpx::distributed namespace and lcos::local::latch has been moved into the hpx namespace. The count_down_and_wait() functionality of latch has been renamed to arrive_and_wait().
  - unique_function has been renamed to move_only_function and moved into namespace hpx. function and function_ref have been moved into namespace hpx.
  - hpx::lcos::split_future changed namespace and is now used as hpx::split_future.
- The new LCI (Lightweight Communication Interface) parcelport was added that supports irregular and asynchronous applications like graph analysis, sparce linear algebra, modern parallel arhcitectures etc. Major features include - Support for advanced communication primitives like two sided send/recv and one sided remote put. - Better multi-threaded performance. - Explicit user control of communication resource. - Flexible signaling mechanisms (synchronizer, completion queue, active message handler).

Breaking changes

- Minimum required C++ standard library is C++17.
- Support for GCC 7 and Clang 8.0.0 and below has been removed.
- CUDA version required updated to 11.4.
- CMake version required updated to 3.18.
- Asio version requires updated to 1.20.0.
- `tagged_pair` and `tagged_tuple` were removed.
- The HPX Customization Point Obejects (CPOs) were updated according to P2300. Namely, `schedule`, `set_value`, `set_error`, `set_done`, `start` and `connect` inherit ``hpx::functional::tag`.
- `tag_dispatch` was renamed to `tag_invoke`.
- `hpx.max_backgroud_threads` was renamed to `hpx.parcel.max_background_threads`.
- The following CMake flags were removed after last release deprecation:

  HPX_SCHEDULER_MAX_TERMINATED_THREADS HPX_WITH_GOOGLE_PERFTOOLS HPX_WITH_INIT_START_OVERLOADS_COMPATIBILITY HPX_HAVE_{COROUTINE,PLUGIN}_GCC_HIDDEN_VISI HPX_TOP_LEVEL HPX_WITH_COMPUTE_CUDA HPX_WITH_ASYNC_CUDA
- `annotate_function` was renamed to `scoped_annotation`.
- `execution::transform` was renamed to `execution::then`.
- `execution::detach` was renamed to `execution::start_detached`.
- `execution::on_sender` was renamed to `execution::schedule_on`.
- `execution::just_on` was renamed to `execution::just_transfer`.
- `set_done` was renamed to `set_stopped`.

Closed issues

- Issue #5812[504] - OctoTiger does not compile with HPX master and CUDA 11.5
- Issue #5784[505] - HPX failing with co_await and hpx::when_all(futures)
- Issue #5774[506] - CMake can't find HPXCacheVariables.cmake

- PR #5785[603] - add cmake code to detect arm64 on macOS
- PR #5783[604] - Moving function and function_ref into namespace hpx
- PR #5781[605] - Updating used version of Visual Studio
- PR #5780[606] - Update Piz Daint Jenkins configurations from gcc/clang 7 to 8
- PR #5778[607] - Updated for_loop.hpp
- PR #5777[608] - Update reference for foreach benchmark
- PR #5775[609] - Move optional into namespace hpx
- PR #5773[610] - Moving barrier to consolidated namespaces
- PR #5772[611] - Adding missing docs for ranges::find_if and find_if_not algorithms
- PR #5771[612] - Moving for_loop into namespace hpx::experimental
- PR #5770[613] - Fixing HIP issues
- PR #5769[614] - Slight improvement of small_vector performance
- PR #5766[615] - Fixing a integral conversion warning
- PR #5765[616] - Adding a sphinx role allowing to link to a file directly in github
- PR #5763[617] - add num_cores facility
- PR #5762[618] - Fix Public API main page
- PR #5761[619] - Add missing inline to mpi_exception.hpp error_message function
- PR #5760[620] - Update cdash build url
- PR #5759[621] - Switch to use generic rostam SLURM partitions
- PR #5758[622] - Adding support for P2300 completion signatures
- PR #5757[623] - Fix missing links in Public API
- PR #5756[624] - Add stop support to when_all
- PR #5755[625] - Support for data-parallelism for mismatch algorithm

- PR #5754[626] - Support for data-parallelism for equal algorithm
- PR #5751[627] - Propagate MPI dependencies to command line handling
- PR #5750[628] - Make sure required MPI initialization flags are properly applied and supported
- PR #5749[629] - P2300 stop token
- PR #5748[630] - Adding environmental query CPOs
- PR #5747[631] - Renaming set_done to set_stopped (as per P2300)
- PR #5745[632] - Modernize serialization module
- PR #5743[633] - Add check for MPICH and set the correct env to support multi-threaded
- PR #5742[634] - Remove obsolete files related to cpuid, etc.
- PR #5741[635] - Support for data-parallelism for adjacent find
- PR #5740[636] - Support for data-parallelism for find algorithms
- PR #5739[637] - Enable the option to attach a debugger on a segmentation fault (linux)
- PR #5738[638] - Fixing spell-checking errors
- PR #5737[639] - Attempt to fix migrate_component issue
- PR #5736[640] - Set commit status from Jenkins also for special branches
- PR #5734[641] - Revert #5586
- PR #5732[642] - Attempt to improve build-id reporting to cdash
- PR #5731[643] - Randomly delay execution of bash scripts launched by Jenkins
- PR #5729[644] - Workaround for CMake/Ninja generator OOM problem
- PR #5727[645] - Moving compression plugins to components directory
- PR #5726[646] - Moving/consolidating parcel coalescing plugin sources
- PR #5725[647] - Making sure headers for serialization filters are being installed
- PR #5723[648] - Moving more tests to modules

2.10.2 *HPX* V1.7.1 (Aug 12, 2021)

This is a bugfix release with a few minor fixes.

General changes

- Added a CMake option to assume that all types are bitwise serializable by default: `HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE`. The default value `OFF` corresponds to the old behaviour.
- Added a version check for Asio. The minimum Asio version supported by *HPX* is 1.12.0.
- Fixed a bug affecting usage of actions, where the internals of *HPX* relied on function addresses being unique. This was fixed by relying on variable addresses being unique instead.
- Made `hpx::util::bind` more strict in checking the validity of placeholders.
- Small performance improvement to spinlocks.
- Adapted the following parallel algorithms to C++20: `inclusive_scan`, `exclusive_scan`, `transform_inclusive_scan`, `transform_exclusive_scan`.

Breaking changes

- The experimental `hpx::execution::simdpar` execution policy (introduced in 1.7.0) was renamed to `hpx::execution::par_simd` for consistency with the other parallel policies.

Closed issues

- Issue #5494[859] - Rename *simdpar* execution policy to *par_simd*
- Issue #5488[860] - *hpx::util::bind* doesn't bounds-check placeholders
- Issue #5486[861] - Possible V1.7.1 release

2.10.3 *HPX* V1.7.0 (Jul 14, 2021)

This release is again focused on C++20 conformance of algorithms. Additionally, many new experimental sender-based algorithms have been added based on the latest proposals.

General changes

- The following algorithms have been adapted to be C++20 conformant:
  - `remove`,
  - `remove_if`,
  - `remove_copy`,
  - `remove_copy_if`,
  - `replace`,
  - `replace_if`,
  - `reverse`, and
  - `lexicographical_compare`.

[871] https://github.com/STEllAR-GROUP/hpx/pull/5439
[872] https://github.com/STEllAR-GROUP/hpx/pull/5436

- When the compiler and standard library support the standard execution policies `std::execution::seq`, `std::execution::par`, and `std::execution::par_unseq` they can now be used in all *HPX* parallel algorithms with equivalent behaviour to the non-task policies `hpx::execution::seq`, `hpx::execution::par`, and `hpx::execution::par_unseq`.
- Vc support has been fixed, after being broken in 1.6.0. In addition, *HPX* now experimentally supports GCC's SIMD implementation, when available. The implementation can be used through the `hpx::execution::simd` and `hpx::execution::simdpar` execution policies.
- The customization points `sync_execute`, `async_execute`, `then_execute`, `post`, `bulk_sync_execute`, `bulk_async_execute`, and `bulk_then_execute` are now implemented using `tag_dispatch` (previously `tag_invoke`). Executors can still be implemented by providing the aforementioned functions as member functions of an executor.
- New functionality, enhancements, and fixes based on P0443r14 (executors proposal) and P1897 (sender-based algorithms) have been added to the `hpx::execution::experimental` namespace. These can be accessed through the `hpx/execution.hpp` and `hpx/local/execution.hpp` headers. In particular, the following sender-based algorithms have been added:
  - `detach`,
  - `ensure_started`,
  - `just`,
  - `just_on`,
  - `let_error`,
  - `let_value`,
  - `on`,
  - `transform`, and
  - `when_all`.

  Additionally, futures now implement the sender concept. `make_future` can be used to turn a sender into a future. All functionality is experimental and can change without notice.
- All `hpx::init` and `hpx::start` overloads now take `std::functions` instead of `hpx::util::function_nonser`. No changes should be required in user code to accommodate this change.
- `hpx::util::unwrapping` and other related unwrapping functionality has been moved up into the `hpx` namespace. Names in `hpx::util` are still usable with a deprecation warning. This functionality can now be accessed through the `hpx/unwrap.hpp` and `hpx/local/unwrap.hpp` headers.
- The default tag for APEX has been update from 2.3.1 to 2.4.0. In particular, this fixes a bug which could lead to hangs in distributed runs.
- The dependency on Boost.Asio has been replaced with the standalone Asio available at https://github.com/chriskohlhoff/asio. By default, a system-installed Asio will be used. `ASIO_ROOT` can be given as a hint to tell CMake where to find Asio. Alternatively, Asio can be fetched automatically using CMake's fetchcontent by setting `HPX_WITH_FETCH_ASIO=ON`. In general, dependencies on Boost have again been reduced.
- Modularization of the library has continued. In this release almost all functionality has been moved into modules. These changes do not generally affect user code. Warnings are still issued for headers that have moved.
- hipBLAS is now optional when compiling with `hipcc`. A warning instead of an error will be printed if hipBLAS is not found during configuration.
- Previously `HPX_COMPUTE_HOST_CODE` was defined in host code only if HPX was configured with CUDA or HIP. In this release `HPX_COMPUTE_HOST_CODE` is always defined in host code.

- An experimental `HPX_WITH_PRECOMPILED_HEADERS` CMake option has been added to use precompiled headers when building *HPX*. This option should not be used on Windows.
- Numerous bug fixes.

Breaking changes

- The minimum required CMake version is now 3.17.
- The minimum required Boost version is now 1.71.0.
- The customization mechanism used to implement and extend sender functionality and algorithms has been renamed from `tag_invoke` to `tag_dispatch`. All customization of sender functionality should be done by overloading `tag_dispatch`.
- The following compatibility options have been removed, along with their compatibility implementations: - `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY` - `HPX_WITH_ACTION_BASE_COMPATIBILITY` - `HPX_WITH_EMBEDDED_THREAD_POOLS_COMPATIBILITY` - `HPX_WITH_POOL_EXECUTOR_COMPATIBILITY`. - `HPX_WITH_PROMISE_ALIAS_COMPATIBILITY` - `HPX_WITH_REGISTER_THREAD_COMPATIBILITY` - `HPX_WITH_REGISTER_THREAD_OVERLOADS_COMPATIBILI` - `HPX_WITH_THREAD_AWARE_TIMER_COMPATIBILITY` - `HPX_WITH_THREAD_EXECUTORS_COMPATIBILITY` - `HPX_WITH_THREAD_POOL_OS_EXECUTOR_COMPATIBILITY`
- The `HPX_WITH_THREAD_SCHEDULERS` CMake option has been removed. All schedulers are now enabled when possible.
- `HPX_WITH_INIT_START_OVERLOADS_COMPATIBILITY` has been turned off by default.

- Issue #5317[884] - Consider making hipblas optional
- Issue #5306[885] - asio fails to build with CUDA 10.0
- Issue #5294[886] - `execution::on` should be based on `execution::schedule`
- Issue #5275[887] - HPX V1.6.0 fails on Fedora release
- Issue #5270[888] - HPX-1.6.0 fails to build on Windows 10
- Issue #5257[889] - Allow triggering the output of OS thread affinity from configuration settings
- Issue #5246[890] - HPX fails to build on ppc64le
- Issue #5232[891] - Annotation using `hpx::util::annotated_function` not working
- Issue #5222[892] - Build and link errors with ittnotify enabled
- Issue #5204[893] - Move algorithms to tag_fallback_dispatch
- Issue #5163[894] - Remove module-specific compatibility and deprecation options
- Issue #5161[895] - Bump required CMake version to 3.17
- Issue #5143[896] - Searching for HPX-Application to generate work on multiple Nodes

Closed pull requests

- PR #5438[897] - Delete datapar/foreach_tests.hpp
- PR #5437[898] - Add back explicit -pthread flags when available
- PR #5435[899] - This adds support for systems that assume all types are bitwise serializable by default
- PR #5434[900] - Update CUDA polling logging to be more verbose
- PR #5433[901] - Fix `when_all_sender` connect for references
- PR #5432[902] - Add deprecation warnings for v1.8
- PR #5431[903] - Rename the new P0443/P2300 executor to `thread_pool_scheduler`
- PR #5430[904] - Revert "Adding the missing defined for `HPX_HAVE_DEPRECATION_WARNINGS`"
- PR #5427[905] - Removing unneeded typedef

- PR #5426[906] - Adding more concept checks for sender/receiver algorithms
- PR #5425[907] - Adding the missing defined for `HPX_HAVE_DEPRECATION_WARNINGS`
- PR #5424[908] - Disable Vc in final docker image created in CI
- PR #5422[909] - Adding `execution::experimental::bulk` algorithm
- PR #5420[910] - Update logic to find threading library
- PR #5418[911] - Reduce max size and number of files in ccache cache
- PR #5417[912] - Final release notes for 1.7.0
- PR #5416[913] - Adapt `uninitialized_value_construct` and `uninitialized_value_construct_n` to C++ 20
- PR #5415[914] - Adapt `uninitialized_default_construct` and `uninitialized_default_construct_n` to C++ 20
- PR #5414[915] - Improve integration of futures and senders
- PR #5413[916] - Fixing sender/receiver code base to compile with MSVC
- PR #5407[917] - Handle exceptions thrown during initialization of parcel handler
- PR #5406[918] - Simplify dispatching to annotation handlers
- PR #5405[919] - Fetch Asio automatically in perftests CI
- PR #5403[920] - Create generic executor that adds annotations to any other executor
- PR #5402[921] - Adapt `uninitialized_fill` and `uninitialized_fill_n` to C++ 20
- PR #5401[922] - Modernize a variety of facilities related to parallel algorithms
- PR #5400[923] - Fix sliding semaphore test
- PR #5399[924] - Rename leftover `tag_fallback_invoke` to `tag_fallback_dispatch`
- PR #5398[925] - Improve logging in AGAS symbol namespace
- PR #5396[926] - Introduce compatibility layer for collective operations
- PR #5394[927] - Enable OTF2 in APEX CI configuration

- PR #5393[928] - Update APEX tag
- PR #5392[929] - Fixing wrong usage of `std::forward`
- PR #5391[930] - Fix forwarding in transform_receiver constructor
- PR #5390[931] - Make sure shared priority scheduler steals tasks on the current NUMA domain when (core) stealing is enabled
- PR #5389[932] - Adapt `uninitialized_move` and `uninitialized_move_n` to C++ 20
- PR #5388[933] - Fixing `gather_there` for used with lvalue reference argument
- PR #5387[934] - Extend thread state logging and change default stealing parameters
- PR #5386[935] - Attempt to fix the startup hang with nodes > 32
- PR #5384[936] - Remove HPX 1.5.0 deprecations
- PR #5382[937] - Prefer installed Asio before considering FetchContent
- PR #5379[938] - Allow using pre-downloaded (not installed) versions of Asio and/or Apex
- PR #5376[939] - Remove unnecessary explicit listing of library modules.rst files in CMakeLists.txt
- PR #5375[940] - Slight performance improvement for `hpx::copy` and `hpx::move` et.al.
- PR #5374[941] - Remove unnecessary moves from future sender implementations
- PR #5373[942] - More changes to clang-cuda Jenkins configuration
- PR #5372[943] - Slight improvements to `min/max/minmax_element` algorithms
- PR #5371[944] - Adapt `uninitialized_copy` and `uninitialized_copy_n` to C++ 20
- PR #5370[945] - Decay types in `just_sender` `value_types` to match stored types
- PR #5367[946] - Disable pkgconfig by default again on macOS
- PR #5365[947] - Use ccache for Jenkins builds on Piz Daint
- PR #5363[948] - Update cudatoolkit module name in clang-cuda Jenkins configuration
- PR #5362[949] - Adding `channel_communicator`
- PR #5361[950] - Fix compilation with MPI enabled

- PR #5360[951] - Update APEX and asio tags
- PR #5359[952] - Fix check for pu-step in single-core case
- PR #5357[953] - Making sure collective operations can be reused by preallocating communicator
- PR #5356[954] - Update API documentation
- PR #5355[955] - Make the `sequenced_executor` `processing_units_count` member function const
- PR #5354[956] - Making sure `default_stack_size` is defined whenever declared
- PR #5353[957] - Add CUDA timestamp support to HPX Hardware Clock
- PR #5352[958] - Adding missing includes
- PR #5351[959] - Adding `enable_logging/disable_logging` API functions
- PR #5350[960] - Adapt lexicographical_compare to C++20
- PR #5349[961] - Update minimum boost version needed on the docs
- PR #5348[962] - Rename `tag_invoke` and related facilities to `tag_dispatch`
- PR #5347[963] - Remove `make_` prefix for executor properties
- PR #5346[964] - Remove and disable compatibility options for 1.7.0
- PR #5343[965] - Fix timed_executor static cast conversion
- PR #5342[966] - Refactor CUDA event polling
- PR #5341[967] - Adding `make_with_annotation` and `get_annotation` properties
- PR #5339[968] - Making sure `hpx::util::hardware::timestamp()` is always defined
- PR #5338[969] - Fixing `timed_executor` specializations of customization points
- PR #5335[970] - Make `partial_algorithm` work with any number of arguments
- PR #5334[971] - Follow up `iter_sent` include on #5225
- PR #5332[972] - Simplify `tag_invoke` and friends
- PR #5331[973] - More work on cleaning up executor CPOs

- PR #5330[974] - Add option to disable pkgconfig generation
- PR #5328[975] - Adapt data parallel support using std-simd
- PR #5327[976] - Fix missing `ifdef HPX_SMT_PAUSE`
- PR #5326[977] - Adding `resize()` to `serialize_buffer` allowing to shrink its size
- PR #5324[978] - Add get member functions to `async_rw_mutex` proxy objects for explicitly getting the wrapped value
- PR #5323[979] - Add `keep_future` algorithm
- PR #5322[980] - Replace executor customization point implementations with `tag_invoke`
- PR #5321[981] - Seperate segmented algorithms for reduce
- PR #5320[982] - Fix `is_sender` trait and other small fixes to p0443 traits
- PR #5319[983] - gcc 11.1 c++20 build fixes
- PR #5318[984] - Make hipblas dependency optional as not always available
- PR #5316[985] - Attempt to fix checking for libatomic
- PR #5315[986] - Add explicit keyword to fixture constructor
- PR #5314[987] - Fix a race condition in async mpi affecting limiting executor
- PR #5312[988] - Use local runtime and local headers in local-only modules and tests
- PR #5311[989] - Add GCC 11 builder to jenkins
- PR #5310[990] - Adding `hpx::execution::experimental::task_group`
- PR #5309[991] - Seperate datapar
- PR #5308[992] - Seperate segmented algorithms for `find`, `find_if`, `find_if_not`
- PR #5307[993] - Seperate segmented algorithms for `fill` and `generate`
- PR #5304[994] - Fix compilation of sender CPOs with nvcc
- PR #5300[995] - Remove `PRIVATE` flag that was propagated into the `LANGUAGES`
- PR #5298[996] - Seperate datapar

- PR #5044[1118] - Add performance test in jenkins and reports

2.10.4 *HPX* V1.6.0 (Feb 17, 2021)

General changes

This release continues the focus on C++20 conformance with multiple new algorithms adapted to be C++20 conformant and becoming customization point objects (CPOs). We have also added experimental support for HIP, allowing previous CUDA features to now be compiled with hipcc and run on AMD GPUs.

- The following algorithms have been adapted to be C++20 conformant: `adjacent_find`, `includes`, `inplace_merge`, `is_heap`, `is_heap_until`, `is_partitioned`, `is_sorted`, `is_sorted_until`, `merge`, `set_difference`, `set_intersection`, `set_symmetric_difference`, `set_union`.
- Experimental HIP support can be enabled by compiling *HPX* with `hipcc`. All CUDA functionality in *HPX* can now be used with HIP. The HIP functionality is for the time being exposed through the same API as the CUDA functionality, i.e. no changes are required in user code. The CUDA, and now HIP, functionality is in the `hpx::cuda` namespace.
- We have added `partial_sort` based on Francisco Tapia's implementation.
- `hpx::init` and `hpx::start` gained new overloads taking an `hpx::init_params` struct in 1.5.0. All overloads not taking an `hpx::init_params` are now deprecated.
- We have added an experimental `fork_join_executor`. This executor can be used for OpenMP-style fork-join parallelism, where the latency of a parallel region is important for performance.
- The `parallel_executor` now uses a hierarchical spawning scheme for bulk execution, which improves data locality and performance.
- `hpx::dataflow` can now be used with executors that inject additional parameters into the call of the user-provided function.
- We have added experimental support for properties as proposed in P2220[1119]. Currently the only supported property is the scheduling hint on `parallel_executor`.
- *`hpx::util::annotated_function`* can now be passed a dynamically generated `std::string`.
- In moving functionality to new namespaces, old names have been deprecated. A deprecation warning will be issued if you are using deprecated functionality, with instructions on how to correct or ignore the warning.

[1112] https://github.com/STEllAR-GROUP/hpx/pull/5144
[1113] https://github.com/STEllAR-GROUP/hpx/pull/5125
[1114] https://github.com/STEllAR-GROUP/hpx/pull/5117
[1115] https://github.com/STEllAR-GROUP/hpx/pull/5099
[1116] https://github.com/STEllAR-GROUP/hpx/pull/5092
[1117] https://github.com/STEllAR-GROUP/hpx/pull/5053
[1118] https://github.com/STEllAR-GROUP/hpx/pull/5044
[1119] https://wg21.link/p2220

- We have removed all support for C and Fortran from our build system.
- We have further reduced the use of Boost types within *HPX* (`boost::system::error_code` and `boost::detail::spinlock`).
- We have enabled more warnings in our CI builds (unused variables and unused typedefs).

Breaking changes

- hpxMP support has been completely removed.
- The `verbs` parcelport has been removed.
- The following compatibility options have been disabled by default: `HPX_WITH_ACTION_BASE_COMPATIBILITY`, `HPX_WITH_REGISTER_THREAD_COMPATIBILITY`, `HPX_WITH_PROMISE_ALIAS_COMPATIBILITY`, `HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY`, `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY`, `HPX_WITH_EMBEDDED_THREAD_POOLS_COMPATIBILITY`, `HPX_WITH_THREAD_POOL_OS_EXECUTOR_COMPATIBI` `HPX_WITH_THREAD_EXECUTORS_COMPATIBILITY`, `HPX_THREAD_AWARE_TIMER_COMPATIBILITY`, `HPX_WITH_POOL_EXECUTOR_COMPATIBILITY`. Unless noted here, the above functionalities do not come with replacements. Unscoped enumerations have been replaced by scoped enumerations. Previously deprecated unscoped enumerations are disabled by `HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY`. Newly deprecated unscoped enumerations have been given deprecation warnings and replaced by scoped enumerations. `hpx::promise` has been replaced with `hpx::distributed::promise`. `hpx::program_options` is a drop-in replacement for `boost::program_options`. `hpx::execution::parallel_executor` now has constructors which take a thread pool, covering the use case of `hpx::threads::executors::pool_executor`. A pool can be supplied with `hpx::resource::get_thread_pool`.

- PR #5140[1155] - Scheduler mode
- PR #5139[1156] - Fix path problem in pre-commit hook, add summary commit line
- PR #5138[1157] - Add program options variable map to resource partitioner init
- PR #5137[1158] - Remove the use of `boost::throw_exception`
- PR #5136[1159] - Make sure codespell checks run on CircleCI
- PR #5132[1160] - Fixing spelling errors
- PR #5131[1161] - Mark `counting_iterator` member functions as `HPX_HOST_DEVICE`
- PR #5130[1162] - Adding specialization for `std::hash<hpx::thread::id>`
- PR #5128[1163] - Fixing environment handling for FreeBSD
- PR #5127[1164] - Fix typo in fibonacci documentation
- PR #5123[1165] - Reduce vector sizes in partial sort benchmarks when running in debug mode
- PR #5122[1166] - Making sure exceptions during runtime initialization are correctly reported
- PR #5121[1167] - Working around hwloc limitation on certain platforms
- PR #5120[1168] - Fixing compatibility warnings in `hpx::transform` implementation
- PR #5119[1169] - Use `sequential_find` and friends from separate detail header
- PR #5116[1170] - Fix compilation with timer pool off
- PR #5114[1171] - Fix 5112 - make sure libatomic is used when needed
- PR #5109[1172] - Remove default runtime mode argument from init overload, again
- PR #5108[1173] - Refactor `iter_sent.hpp` to make structs lowercase
- PR #5107[1174] - Relax `dataflow` internals

2.10.5 *HPX* V1.5.1 (Sep 30, 2020)

General changes

This is a patch release. It contains the following changes:

- Remove restriction on suspending runtime with multiple localities, users are now responsible for synchronizing work between localities before suspending.
- Fixes several compilation problems and warnings.
- Adds notes in the documentation explaining how to cite HPX.

Closed issues

- Issue #4971[1294] - Parallel sort fails to compile with C++20
- Issue #4950[1295] - Build with *HPX_WITH_PARCELPORT_ACTION_COUNTERS ON* fails
- Issue #4940[1296] - Codespell report for "HPX" (on fossies.org)
- Issue #4937[1297] - Allow suspension of runtime for multiple localities

Closed pull requests

- PR #4982[1298] - Add page about citing HPX to documentation
- PR #4981[1299] - Adding the missing include
- PR #4974[1300] - Remove leftover format export hack
- PR #4972[1301] - Removing use of get_temporary_buffer and return_temporary_buffer
- PR #4963[1302] - Renaming files to avoid warnings from the vs build system
- PR #4951[1303] - Fixing build if HPX_WITH_PARCELPORT_ACTION_COUNTERS=On

- PR #4939[1307] - Small changes

2.10.6 *HPX* V1.5.0 (Sep 02, 2020)

General changes

The main focus of this release is on APIs and C++20 conformance. We have added many new C++20 features and adapted multiple algorithms to be fully C++20 conformant. As part of the modularization we have begun specifying the public API of *HPX* in terms of headers and functionality, and aligning it more closely to the C++ standard. All non-distributed modules are now in place, along with an experimental option to completely disable distributed features in *HPX*. We have also added experimental asynchronous MPI and CUDA executors. Lastly this release introduces CMake targets for depending projects, performance improvements, and many bug fixes.

- We have added the C++20 features `hpx::jthread` and `hpx::stop_token`. `hpx::condition_variable_any` now exposes new functions supporting `hpx::stop_token`.
- We have added `hpx::stable_sort` based on Francisco Tapia's implementation.
- We have adapted existing synchronization primitives to be fully conformant C++20: `hpx::barrier`, `hpx::latch`, `hpx::counting_semaphore`, and `hpx::binary_semaphore`.
- We have started using customization point objects (CPOs) to make the corresponding algorithms fully conformant to C++20 as well as to make algorithm extension easier for the user. `all_of`/`any_of`/`none_of`, `copy`, `count`, `destroy`, `equal`, `fill`, `find`, `for_each`, `generate`, `mismatch`, `move`, `reduce`, `transform_reduce` are using those CPOs (all in namespace `hpx`). We also have adapted their corresponding `hpx::ranges` versions to be conforming to C++20 in this release.
- We have adapted support for `co_await` to C++20, in addition to `hpx::future` it now also supports `hpx::shared_future`. We have also added allocator support for futures returned by `co_return`. It is no longer in the `experimental` namespace.
- We added serialization support for `std::variant` and `std::tuple`.
- `result_of` and `is_callable` are now deprecated and replaced by `invoke_result` and `is_invocable` to conform to C++20.
- We continued with the modularization, making it easier for us to add the new experimental `HPX_WITH_DISTRIBUTED_RUNTIME` CMake option (see below) . An significant amount of headers have been deprecated. We adapted the namespaces and headers we could to be closer to the standard ones (*Public API*). Depending code should still compile, however warnings are now generated instructing to change the include statements accordingly.
- It is now possible to have a basic CUDA support including a helper function to get a future from a CUDA stream and target handling. They are available under the `hpx::cuda::experimental` namespace and they can be enabled with the `-DHPX_WITH_ASYNC_CUDA=ON` CMake option.
- We added a new `hpx::mpi::experimental` namespace for getting futures from an asynchronous MPI call and a new minimal MPI executor `hpx::mpi::experimental::executor`. These can be enabled with the `-DHPX_WITH_ASYNC_MPI=On` CMake option.

[1304] https://github.com/STEllAR-GROUP/hpx/pull/4946
[1305] https://github.com/STEllAR-GROUP/hpx/pull/4944
[1306] https://github.com/STEllAR-GROUP/hpx/pull/4941
[1307] https://github.com/STEllAR-GROUP/hpx/pull/4939

- A polymorphic executor has been implemented to reduce compile times as a function accepting executors can potentially be instantiated only once instead of multiple times with different executors. It accepts the function signature as a template argument. It needs to be constructed from any other executor. Please note, that the function signatures that can be scheduled using `then_execute`, `bulk_sync_execute`, `bulk_async_execute` and `bulk_then_execute` are slightly different (See the comment in PR #4514[1308] for more details).
- The underlying executor of `block_executor` has been updated to a newer one.
- We have added a parameter to `auto_chunk_size` to control the amount of iterations to measure.
- All executor parameter hooks can now be exposed through the executor itself. This will allow to deprecate the `.with()` functionality on execution policies in the future. This is also a first step towards simplifying our executor APIs in preparation for the upcoming C++23 executors (senders/receivers).
- We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`. Please note this is a breaking change without backwards-compatibility option. We have converted all of those APIs to be based on customization point objects. Two new executors have been added to enable easy integration of the existing resiliency features with other facilities (like the parallel algorithms): `replay_executor` and `replicate_executor`.
- We have added performance counters type information (`aggregating`, `monotonically increasing`, `average count`, `average timer`, etc.).
- HPX threads are now re-scheduled on the same worker thread they were suspended on to avoid cache misses from moving from one thread to the other. This behavior doesn't prevent the thread from being stolen, however.
- We have added a new configuration option `hpx.exception_verbosity` to allow to control the level of verbosity of the exceptions (3 levels available).
- `broadcast_to`, `broadcast_from`, `scatter_to` and `scatter_from` have been added to the collectives, modernization of `gather_here` and `gather_there` with futures taken by rvalue references. See the breaking change on `all_to_all` in the next section. None of the collectives need supporting macros anymore (e.g. specifying the data types used for a collective operation using `HPX_REGISTER_ALLGATHER` and similar is not needed anymore).
- New API functions have been added: a) to get the number of cores which are idle (`hpx::get_idle_core_count`) and b) returning a bitmask representing the currently idle cores (`hpx::get_idle_core_mask`).
- We have added an experimental option to only enable the local runtime, you can disable the distributed runtime with `HPX_WITH_DISTRIBUTED_RUNTIME=OFF`. You can also enable the local runtime by using the `--hpx:local` runtime option.
- We fixed task annotations for actions.
- The alias `hpx::promise` to `hpx::lcos::promise` is now deprecated. You can use `hpx::lcos::promise` directly instead. `hpx::promise` will refer to the local-only promise in the future.
- We have added a `prepare_checkpoint` API function that calculates the amount of necessary buffer space for a particular set of arguments checkpointed.
- We have added `hpx::upgrade_lock` and `hpx::upgrade_to_unique_lock`, which make `hpx::shared_mutex` (and similar) usable in more flexible ways.
- We have changed the CMake targets exposed to the user, it now includes `HPX::hpx`, `HPX::wrap_main` (`int main` as the first *HPX* thread of the application, see *Starting the HPX runtime*), `HPX::plugin`, `HPX::component`. The CMake variables `HPX_INCLUDE_DIRS` and `HPX_LIBRARIES` are deprecated and will be removed in a future release, you should now link directly to the `HPX::hpx` CMake target.

[1308] https://github.com/STEllAR-GROUP/hpx/pull/4514

- A new example is demonstrating how to create and use a wrapping executor (`quickstart/executor_with_thread_hooks.cpp`)
- A new example is demonstrating how to disable thread stealing during the execution of parallel algorithms (`quickstart/disable_thread_stealing_executor.cpp`)
- We now require for our CMake build system configuration files to be formatted using cmake-format.
- We have removed more dependencies on various Boost libraries.
- We have added an experimental option enabling unity builds of HPX using the `-DHPX_WITH_UNITY_BUILD=On` CMake option.
- Many bug fixes.

Breaking changes

- *HPX* now requires a C++14 capable compiler. We have set the *HPX* C++ standard automatically to C++14 and if it needs to be set explicitly, it should be specified through the `CMAKE_CXX_STANDARD` setting as mandated by CMake. The `HPX_WITH_CXX*` variables are now deprecated and will be removed in the future.
- Building and using HPX is now supported only when using CMake V3.13 or later, Boost V1.64 or newer, and when compiling with clang V5, gcc V7, or VS2019, or later. Other compilers might still work but have not been tested thoroughly.
- We have added a `hpx::init_params` struct to pass parameters for *HPX* initialization e.g. the resource partitioner callback to initialize thread pools (*Using the resource partitioner*).
- The `all_to_all` algorithm is renamed to `all_gather`, and the new `all_to_all` algorithm is not compatible with the old one.
- We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`.

- PR #4921[1409] - Update the release notes for the release candidate 3
- PR #4920[1410] - Disable libcds release
- PR #4919[1411] - Make cuda event pool dynamic instead of fixed size
- PR #4917[1412] - Move chrono functionality to hpx::chrono namespace
- PR #4916[1413] - HPX_HAVE_DEPRECATION_WARNINGS needs to be set even when disabled
- PR #4915[1414] - Moving more action related files to actions modules
- PR #4914[1415] - Add alias targets with namespaces used for exporting
- PR #4912[1416] - Aggregate initialize CPOs
- PR #4910[1417] - Explicitly specify hwloc root on Jenkins CSCS builds
- PR #4908[1418] - Fix algorithms documentation
- PR #4907[1419] - Remove HPX::hpx_no_wrap_main target
- PR #4906[1420] - Fixing unused variable warning
- PR #4905[1421] - Adding specializations for simple for_loops
- PR #4904[1422] - Update boost to 1.74.0 for the newest jenkins configs
- PR #4903[1423] - Hide GITHUB_TOKEN environment variables from environment variable output
- PR #4902[1424] - Cancel previous pull requests builds before starting a new one with Jenkins
- PR #4901[1425] - Update public API list with updated algorithms
- PR #4899[1426] - Suggested changes for HPX V1.5 release notes
- PR #4898[1427] - Minor tweak to hpx::equal implementation
- PR #4896[1428] - Making generate() and generate_n conforming to C++20
- PR #4895[1429] - Update apex tag
- PR #4894[1430] - Fix exception handling for tasks

- PR #4893[1431] - Remove last use of std::result_of, removed in C++20
- PR #4892[1432] - Adding replay_executor and replicate_executor
- PR #4889[1433] - Restore old behaviour of not requiring linking to hpx_wrap when HPX_WITH_DYNAMIC_HPX_MAIN=OFF
- PR #4887[1434] - Making sure remotely thrown (non-hpx) exceptions are properly marshaled back to invocation site
- PR #4885[1435] - Adapting hpx::find and friends to C++20
- PR #4884[1436] - Adapting mismatch to C++20
- PR #4883[1437] - Adapting hpx::equal to be conforming to C++20
- PR #4882[1438] - Fixing exception handling for hpx::copy and adding missing tests
- PR #4881[1439] - Adds different runtime exception when registering thread with the HPX runtime
- PR #4876[1440] - Adding example demonstrating how to disable thread stealing during the execution of parallel algorithms
- PR #4874[1441] - Adding non-policy tests to all_of, any_of, and none_of
- PR #4873[1442] - Set CUDA compute capability on rostam Jenkins builds
- PR #4872[1443] - Force partitioned vector scan tests to run serially
- PR #4870[1444] - Making move conforming with C++20
- PR #4869[1445] - Making destroy and destroy_n conforming to C++20
- PR #4868[1446] - Fix miscellaneous header problems
- PR #4867[1447] - Add CPOs for for_each
- PR #4865[1448] - Adapting count and count_if to be conforming to C++20
- PR #4864[1449] - Release notes 1.5.0
- PR #4863[1450] - adding libcds-hpx tag to prepare for hpx1.5 release
- PR #4862[1451] - Adding version specific deprecation options
- PR #4861[1452] - Limiting executor improvements

- PR #4860[1453] - Making fill and fill_n compatible with C++20
- PR #4859[1454] - Adapting all_of, any_of, and none_of to C++20
- PR #4857[1455] - Improve libCDS integration
- PR #4856[1456] - Correct typos in the documentation of the hpx performance counters
- PR #4854[1457] - Removing obsolete code
- PR #4853[1458] - Adding test that derives component from two other components
- PR #4852[1459] - Fix mpi_ring test in distributed mode by ensuring all ranks run hpx_main
- PR #4851[1460] - Converting resiliency APIs to tag_invoke based CPOs
- PR #4849[1461] - Enable use of future_overhead test when DISTRIBUTED_RUNTIME is OFF
- PR #4847[1462] - Fixing 'error prone' constructs as reported by Codacy
- PR #4846[1463] - Disable Boost.Asio concepts support
- PR #4845[1464] - Fix PAPI counters
- PR #4843[1465] - Remove dependency on various Boost headers
- PR #4841[1466] - Rearrange public API headers
- PR #4840[1467] - Fixing TSS problems during thread termination
- PR #4839[1468] - Fix async_cuda build problems when distributed runtime is disabled
- PR #4837[1469] - Restore compatibility for old (now deprecated) copy algorithms
- PR #4836[1470] - Adding CPOs for hpx::reduce
- PR #4835[1471] - Remove *using util::result_of* from namespace hpx
- PR #4834[1472] - Fixing the calculation of the number of idle cores and the corresponding idle masks
- PR #4833[1473] - Allow thread function destructors to yield
- PR #4832[1474] - Fixing assertion in split_gids and memory leaks in 1d_stencil_7
- PR #4831[1475] - Making sure MPI_CXX_COMPILE_FLAGS is interpreted as a sequence of options

- PR #4830[1476] - Update documentation on using HPX::wrap_main
- PR #4827[1477] - Update clang-newest configuration to use clang 10
- PR #4826[1478] - Add Jenkins configuration for rostam
- PR #4825[1479] - Move all CUDA functionality to hpx::cuda::experimental namespace
- PR #4824[1480] - Add support for building master/release branches to Jenkins configuration
- PR #4821[1481] - Implement customization point for hpx::copy and hpx::ranges::copy
- PR #4819[1482] - Allow finding Boost components before finding HPX
- PR #4817[1483] - Adding range version of stable sort
- PR #4815[1484] - Fix a wrong #ifdef for IO/TIMER pools causing build errors
- PR #4814[1485] - Replace hpx::function_nonser with std::function in error module
- PR #4809[1486] - Foreach adapt
- PR #4808[1487] - Make internal algorithms functions const
- PR #4807[1488] - Add Jenkins configuration for running on Piz Daint
- PR #4806[1489] - Update documentation links to new domain name
- PR #4805[1490] - Applying changes that resolve time complexity issues in sort
- PR #4803[1491] - Adding implementation of stable_sort
- PR #4802[1492] - Fix datapar header paths
- PR #4801[1493] - Replace boost::shared_array<T> with std::shared_ptr<T[]> if supported
- PR #4799[1494] - Fixing #include paths in compatibility headers
- PR #4798[1495] - Include the main module header (fixes partially #4488)
- PR #4797[1496] - Change cmake targets
- PR #4794[1497] - Removing 128bit integer emulation
- PR #4793[1498] - Make sure global variable is handled properly

- PR #4792[1499] - Replace enable_if with **HPX_CONCEPT_REQUIRES_** and add is_sentinel_for constraint
- PR #4790[1500] - Move deprecation warnings from base template to template specializations for result_of etc. structs
- PR #4789[1501] - Fix hangs during assertion handling and distributed runtime construction
- PR #4788[1502] - Fixing inclusive transform scan algorithm to properly handle initial value
- PR #4785[1503] - Fixing barrier test
- PR #4784[1504] - Fixing deleter argument bindings in serialize_buffer
- PR #4783[1505] - Add coveralls badge
- PR #4782[1506] - Make header tests parallel again
- PR #4780[1507] - Remove outdated comment about hpx::stop in documentation
- PR #4776[1508] - debug print improvements
- PR #4775[1509] - Checkpoint cleanup
- PR #4771[1510] - Fix compilation with HPX_WITH_NETWORKING=OFF
- PR #4767[1511] - Remove all force linking leftovers
- PR #4765[1512] - Fix 1d stencil index calculation
- PR #4764[1513] - Force some tests to run serially
- PR #4762[1514] - Update pointees in compatibility headers
- PR #4761[1515] - Fix running and building of execution module tests on CircleCI
- PR #4760[1516] - Storing hpx_options in global property to speed up summary report
- PR #4759[1517] - Reduce memory requirements for our main shared state
- PR #4757[1518] - Fix mimalloc linking on Windows
- PR #4756[1519] - Fix compilation issues
- PR #4753[1520] - Re-adding API functions that were lost during merges
- PR #4751[1521] - Revert "Create coverage reports and upload them to codecov.io"

- PR #4671[1568] - Deprecate hpx::promise alias to hpx::lcos::promise
- PR #4670[1569] - Explicitly instantiate get_exception
- PR #4667[1570] - Add *stopValue* in *Sentinel* struct instead of *Iterator*
- PR #4666[1571] - Add release build on Windows to GitHub actions
- PR #4664[1572] - Creating itt_notify module.
- PR #4663[1573] - Mpi fixes
- PR #4659[1574] - Making sure declarations match definitions in register_locks implementation
- PR #4655[1575] - Fixing task annotations for actions
- PR #4653[1576] - Making sure APEX is linked into every application, if needed
- PR #4651[1577] - Update get_function_annotation.hpp
- PR #4646[1578] - Runtime type
- PR #4645[1579] - Add a few more API headers
- PR #4644[1580] - Fixing support for mpirun (and similar)
- PR #4643[1581] - Fixing the fix for get_idle_core_count() API
- PR #4638[1582] - Remove HPX_API_EXPORT missed in previous cleanup
- PR #4636[1583] - Adding C++20 barrier
- PR #4635[1584] - Adding C++20 latch API
- PR #4634[1585] - Adding C++20 counting semaphore API
- PR #4633[1586] - Unify execution parameters customization points
- PR #4632[1587] - Adding missing bulk_sync_execute wrapper to example executor
- PR #4631[1588] - Updates to documentation; grammar edits.
- PR #4630[1589] - Updates to documentation; moved hyperlink
- PR #4624[1590] - Export set_self_ptr in thread_data.hpp instead of with forward declarations where used

- PR #4623[1591] - Clean up export macros
- PR #4621[1592] - Trigger an error for older boost versions on power architectures
- PR #4617[1593] - Ignore user-set compatibility header options if the module does not have compatibility headers
- PR #4616[1594] - Fix cmake-format warning
- PR #4615[1595] - Add handler for serializing custom exceptions
- PR #4614[1596] - Fix error message when HPX_IGNORE_CMAKE_BUILD_TYPE_COMPATIBILITY=OFF
- PR #4613[1597] - Make partitioner constructor private
- PR #4611[1598] - Making auto_chunk_size execute the given function using the given executor
- PR #4610[1599] - Making sure the thread-local lock registration data is moving to the core the suspended HPX thread is resumed on
- PR #4609[1600] - Adding an API function that exposes the number of idle cores
- PR #4608[1601] - Fixing moodycamel namespace
- PR #4607[1602] - Moving winsocket initialization to core library
- PR #4606[1603] - Local runtime module etc.
- PR #4604[1604] - Add config_registry module
- PR #4603[1605] - Deal with distributed modules in their respective CMakeLists.txt
- PR #4602[1606] - Small module fixes
- PR #4598[1607] - Making sure current_executor and service_executor functions are linked into the core library
- PR #4597[1608] - Adding broadcast_to/broadcast_from to collectives module
- PR #4596[1609] - Fix performance regression in block_executor
- PR #4595[1610] - Making sure main.cpp is built as a library if HPX_WITH_DYNAMIC_MAIN=OFF
- PR #4592[1611] - Futures module
- PR #4591[1612] - Adapting co_await support for C++20
- PR #4590[1613] - Adding missing exception test for for_loop()

2.10.7 *HPX* V1.4.1 (Feb 12, 2020)

General changes

This is a bugfix release. It contains the following changes:

- Fix compilation issues on Windows, macOS, FreeBSD, and with gcc 10
- Install missing `pdb` files on Windows
- Allow running tests using an installed version of *HPX*
- Skip MPI finalization if HPX has not initialized MPI
- Give a hard error when attempting to use IO counters on Windows

Closed issues

- Issue #4320[1807] - HPX 1.4.0 does not compile with gcc 10
- Issue #4336[1808] - Building HPX 1.4.0 with IO Counters breaks (Windows)
- Issue #4334[1809] - HPX `Debug` and `RelWithDebinfo` builds on Windows not installing `.pdb` files
- Issue #4322[1810] - Undefine VT1 and VT2 after boost includes
- Issue #4314[1811] - Compile error on 1.4.0
- Issue #4307[1812] - `ld: error: duplicate symbol: freebsd_environ`

- PR #4310[1820] - Remove environment handling from `exception.cpp`

2.10.8 *HPX* V1.4.0 (January 15, 2020)

General changes

- We have added the collectives `all_to_all` and `all_reduce`.
- We have added APIs for resiliency, which allows replication and replay for failed tasks. See the *documentation* for more details.
- Components can now be checkpointed.
- Performance improvements to schedulers and coroutines. A significant change is the addition of stackless coroutines. These are to be used for tasks that do not need to be suspended and can reduce overheads noticeably in applications with short tasks. A stackless coroutine can be created with the new stack size `thread_stacksize_nostack`.
- We have added an implementation of `unique_any`, which is a non-copyable version of `any`.
- The `shared_priority_queue_scheduler` has been improved. It now has lower overheads than the default scheduler in many situations. Unlike the default scheduler it fully supports NUMA scheduling hints. Enable it with the command line option `--hpx:queuing=shared-priority`. This scheduler should still be considered experimental, but its use is encouraged in real applications to help us make it production ready.
- We have added the performance counters `background-receive-duration` and `background-receive-overhead` for inspecting the time and overhead spent on receiving parcels in the background.
- Compilation time has been further improved when `HPX_WITH_NETWORKING=OFF`.
- We no longer require compiled Boost dependencies in certain configurations. This requires at least Boost 1.70, compiling on x86 with GCC 9, clang (libc++) 9, or VS2019 in C++17 mode. The dependency on Boost.Filesystem can explicitly be turned on with `HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY=ON` (it is off by default if the standard library supports `std::filesystem`). Boost.ProgramOptions has been copied into the HPX repository. We have a compatibility layer for users who must explicitly use

[1813] https://github.com/STEllAR-GROUP/hpx/pull/4376
[1814] https://github.com/STEllAR-GROUP/hpx/pull/4357
[1815] https://github.com/STEllAR-GROUP/hpx/pull/4353
[1816] https://github.com/STEllAR-GROUP/hpx/pull/4343
[1817] https://github.com/STEllAR-GROUP/hpx/pull/4337
[1818] https://github.com/STEllAR-GROUP/hpx/pull/4335
[1819] https://github.com/STEllAR-GROUP/hpx/pull/4315
[1820] https://github.com/STEllAR-GROUP/hpx/pull/4310

Boost.ProgramOptions instead of the ProgramOptions provided by HPX. To remove the dependency `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY` must be explicitly set to `OFF`. This option will be removed in a future release. We have also removed several other header-only dependencies on Boost.

- It is now possible to use the process affinity mask set by tools like `numactl` and various batch environments with the command line option *`--hpx:use-process-mask`*. Enabling this option implies *`--hpx:ignore-batch-env`*.
- It is now possible to create standalone thread pools without starting the runtime. See the `standalone_thread_pool_executor.cpp` test in the `execution` module for an example.
- Tasks annotated with *`hpx::util::annotated_function`* now have their correct name when using APEX to generate OTF2 files.
- Cloning of APEX was defective in previous releases (it required manual intervention to check out the correct tag or branch). This has been fixed.
- The option `HPX_WITH_MORE_THAN_64_THREADS` is now ignored and will be removed in a future release. The value is instead derived directly from `HPX_WITH_MAX_CPU_COUNT` option.
- We have deprecated compiling in C++11 mode. The next release will require a C++14 capable compiler.
- We have deprecated support for the Vc library. This option will be replaced with SIMD support from the standard library in a future release.
- We have significantly refactored our CMake setup. This is intended to be a non-breaking change and will allow for using HPX through CMake targets in the future.
- We have continued modularizing the HPX library. In the process we have rearranged many header files into module-specific directories. All moved headers have compatibility headers which forward from the old location to the new location, together with a deprecation warning. The compatibility headers will eventually be removed.
- We now enforce formatting with `clang-format` on the majority of our source files.
- We have added SPDX license tags to all files.
- Many bugfixes.

Breaking changes

- The `HPX_WITH_THREAD_COMPATIBILITY` option and the associated compatibility layer has been removed.
- The `HPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY` option and the associated compatibility layer has been removed.
- The `HPX_WITH_UNWRAPPED_COMPATIBLITY` option and the associated compatibility layer has been removed.

- Issue #4115[1847] - dependency chaining error with APEX
- Issue #4107[1848] - Initializing runtime without entry point function and command line arguments
- Issue #4105[1849] - Bug in `hpx:bind=numa-balanced`
- Issue #4101[1850] - Bound tasks
- Issue #4100[1851] - Add SPDX identifier to all files
- Issue #4085[1852] - `hpx_topology` library should depend on hwloc
- Issue #4067[1853] - HPX fails to build on macOS
- Issue #4056[1854] - Building without thread manager idle backoff fails
- Issue #4052[1855] - Enforce `clang-format` style for modules
- Issue #4032[1856] - Simple hello world fails to launch correctly
- Issue #4030[1857] - Allow threads to skip context switching
- Issue #4029[1858] - Add support for mimalloc
- Issue #4005[1859] - Can't link HPX when APEX enabled
- Issue #4002[1860] - Missing header for algorithm module
- Issue #3989[1861] - conversion from `long` to `unsigned int` requires a narrowing conversion on MSVC
- Issue #3958[1862] - `/statistics/average@` perf counter can't be created
- Issue #3953[1863] - CMake errors from `HPX_AddPseudoDependencies`
- Issue #3941[1864] - CMake error for APEX install target
- Issue #3940[1865] - Convert pseudo-doxygen function documentation into actual doxygen documentation
- Issue #3935[1866] - HPX compiler match too strict?
- Issue #3929[1867] - Buildbot failures on latest HPX stable
- Issue #3912[1868] - I recommend publishing a version that does not depend on the boost library
- Issue #3890[1869] - `hpx.ini` not working

- Issue #3883[1870] - cuda compilation fails because of `-faligned-new`
- Issue #3879[1871] - HPX fails to configure with `-DHPX_WITH_TESTS=OFF`
- Issue #3871[1872] - `dataflow` does not support void allocators
- Issue #3867[1873] - Latest HTML docs placed in wrong directory on GitHub pages
- Issue #3866[1874] - Make sure all tests use `HPX_TEST*` macros and not `HPX_ASSERT`
- Issue #3857[1875] - CMake all-keyword or all-plain for `target_link_libraries`
- Issue #3856[1876] - `hpx_setup_target` adds rogue flags
- Issue #3850[1877] - HPX fails to build on POWER8 with Clang7
- Issue #3848[1878] - Remove `lva` member from `thread_init_data`
- Issue #3838[1879] - `hpx::parallel::count/count_if` failing tests
- Issue #3651[1880] - `hpx::parallel::transform_reduce` with non const reference as lambda parameter
- Issue #3560[1881] - Apex integration with HPX not working properly
- Issue #3322[1882] - No warning when mixing debug/release builds

Closed pull requests

- PR #4300[1883] - Checks for `MPI_Init` being called twice
- PR #4299[1884] - Small CMake fixes
- PR #4298[1885] - Remove extra call to annotate function that messes up traces
- PR #4296[1886] - Fixing collectives locking problem
- PR #4295[1887] - Do not check `LICENSE_1_0.txt` for inspect violations
- PR #4293[1888] - Applying two small changes fixing carious MSVC/Windows problems
- PR #4285[1889] - Delete `apex.hpp`
- PR #4276[1890] - Disable doxygen generation for `hpx/debugging/print.hpp` file
- PR #4275[1891] - Make sure APEX is linked to even when not explicitly referenced

- PR #4240[1915] - Mostly fix clang CUDA compilation
- PR #4238[1916] - Google Season of Docs updates to documentation; grammar edits.
- PR #4237[1917] - fixing annotated task to use the name, not the desc
- PR #4236[1918] - Move module print summary to modules
- PR #4235[1919] - Don't use alignas in `cache_{aligned,line}_data`
- PR #4234[1920] - Add basic overview sentence to all modules
- PR #4230[1921] - Add OS X builds to Travis CI
- PR #4229[1922] - Remove leftover queue compatibility checks
- PR #4226[1923] - Fixing APEX shutdown by explicitly shutting down throttling
- PR #4225[1924] - Allow `CMAKE_INSTALL_PREFIX` to be a relative path
- PR #4224[1925] - Deprecate verbs parcelport
- PR #4222[1926] - Update `register_{thread,work}` namespaces
- PR #4221[1927] - Changing `HPX_GCC_VERSION` check from `70000` to `70300`
- PR #4218[1928] - Google Season of Docs updates to documentation; grammar edits.
- PR #4217[1929] - Google Season of Docs updates to documentation; grammar edits.
- PR #4216[1930] - Fixing gcc warning on 32bit platforms (integer truncation)
- PR #4214[1931] - Apex callback refactoring
- PR #4213[1932] - Clean up allocator checks for dependent projects
- PR #4212[1933] - Google Season of Docs updates to documentation; grammar edits.
- PR #4211[1934] - Google Season of Docs updates to documentation; contributing to hpx
- PR #4210[1935] - Attempting to fix Intel compilation
- PR #4209[1936] - Fix CUDA 10 build
- PR #4205[1937] - Making sure that differences in `CMAKE_BUILD_TYPE` are not reported on multi-configuration cmake generators

- PR #4203[1938] - Deprecate Vc
- PR #4202[1939] - Fix CUDA configuration
- PR #4200[1940] - Making sure `hpx_wrap` is not passed on to linker on non-Linux systems
- PR #4198[1941] - Fix `execution_agent.cpp` compilation with GCC 5
- PR #4197[1942] - Remove deprecated options for 1.4.0 release
- PR #4196[1943] - minor fixes for building on OSX Darwin
- PR #4195[1944] - Use full clone on CircleCI for pushing stable tag
- PR #4193[1945] - Add scheduling hints to hello_world_distributed
- PR #4192[1946] - Set up CUDA in HPXConfig.cmake
- PR #4191[1947] - Export allocators root variables
- PR #4190[1948] - Don't use `constexpr` in `thread_data` with GCC <= 6
- PR #4189[1949] - Only use `quick_exit` if available
- PR #4188[1950] - Google Season of Docs updates to documentation; writing single node hpx applications
- PR #4186[1951] - correct vc to cuda in cuda cmake
- PR #4184[1952] - Resetting some cached variables to make sure those are re-filled
- PR #4183[1953] - Fix `hpxcxx` configuration
- PR #4181[1954] - Rename base libraries var
- PR #4180[1955] - Move header left behind earlier to plugin module
- PR #4179[1956] - Moving `zip_iterator` and `transform_iterator` to iterator_support module
- PR #4178[1957] - Move checkpointing support to its own module
- PR #4177[1958] - Small const fix to `basic_execution` module
- PR #4176[1959] - Add back `HPX_LIBRARIES` and friends to `HPXConfig.cmake`
- PR #4175[1960] - Make Vc public and add it to `HPXConfig.cmake`

- PR #4173[1961] - Wait for runtime to be running before returning from hpx::start
- PR #4172[1962] - More protection against shutdown problems in error handling scenarios.
- PR #4171[1963] - Ignore lock in `condition_variable::wait`
- PR #4170[1964] - Adding APEX dependency to MPI parcelport
- PR #4168[1965] - Adding utility include
- PR #4167[1966] - Add a condition to setup the external libraries
- PR #4166[1967] - Add an `INTERNAL_FLAGS` option to link to `hpx_internal_flags`
- PR #4165[1968] - Forward `HPX_*` cmake cache variables to external projects
- PR #4164[1969] - Affinity and batch environment modules
- PR #4162[1970] - Handle `quick exit`
- PR #4160[1971] - Using `target_link_libraries` for cmake versions >= 3.12
- PR #4159[1972] - Make sure `HPX_WITH_NATIVE_TLS` is forwarded to dependent projects
- PR #4158[1973] - Adding allocator imported target as a dependency of allocator module
- PR #4157[1974] - Add `hpx_memory` as a dependency of parcelport plugins
- PR #4156[1975] - Stackless coroutines now can refer to themselves (through get_self() and friends)
- PR #4154[1976] - Added CMake policy CMP0060 for HPX applications.
- PR #4153[1977] - add header `iomanip` to tests and tool
- PR #4152[1978] - Casting MPI tag value
- PR #4149[1979] - Add back private `m_desc` member variable in program_options module
- PR #4147[1980] - Resource partitioner and threadmanager modules
- PR #4146[1981] - Google Season of Docs updates to documentation; creating hpx projects
- PR #4145[1982] - Adding basic support for stackless threads
- PR #4143[1983] - Exclude `test_client_1950` from all target

[1983] https://github.com/STEllAR-GROUP/hpx/pull/4143

- PR #4142[1984] - Add a new `thread_pool_executor`
- PR #4140[1985] - Google Season of Docs updates to documentation; why hpx
- PR #4139[1986] - Remove runtime includes from coroutines module
- PR #4138[1987] - Forking `boost::intrusive_ptr` and adding it as `hpx::intrusive_ptr`
- PR #4137[1988] - Fixing TSS destruction
- PR #4136[1989] - HPX.Compute modules
- PR #4133[1990] - Fix `block_executor`
- PR #4131[1991] - Applying fixes based on reports from PVS Studio
- PR #4130[1992] - Adding missing header to build system
- PR #4129[1993] - Fixing compilation if `HPX_WITH_DATAPAR_VC` is enabled
- PR #4128[1994] - Renaming `moveonly_any` to `unique_any`
- PR #4126[1995] - Attempt to fix `basic_any` constructor for gcc 7
- PR #4125[1996] - Changing `extra_archive_data` implementation
- PR #4124[1997] - Don't link to Boost.System unless required
- PR #4122[1998] - Add kernel launch helper utility (+saxpy demo) and merge in octotiger changes
- PR #4121[1999] - Fixing migration test if networking is disabled.
- PR #4120[2000] - Google Season of Docs updates to documentation; hpx build system v1
- PR #4119[2001] - Making sure `chunk_size` and `max_chunk` are actually applied to parallel algorithms if specified
- PR #4117[2002] - Make CircleCI formatting check store diff
- PR #4116[2003] - Fix automatically setting C++ standard
- PR #4114[2004] - Module serialization
- PR #4113[2005] - Module datastructures
- PR #4111[2006] - Fixing performance regression introduced earlier

- PR #4110[2007] - Adding missing SPDX tags
- PR #4109[2008] - Overload for start without entry point/argv.
- PR #4108[2009] - Making sure C++ standard is properly detected and propagated
- PR #4106[2010] - use `std::round` for guaranteed rounding without errors
- PR #4104[2011] - Extend `scheduler_mode` with new `work_stealing` and task assignment modes
- PR #4103[2012] - Add this to lambda capture list
- PR #4102[2013] - Add spdx license and check
- PR #4099[2014] - Module coroutines
- PR #4098[2015] - Fix append module path in module CMakeLists template
- PR #4097[2016] - Function tests
- PR #4096[2017] - Removing return of `thread_result_type` from functions not needing them
- PR #4095[2018] - Stop-gap measure until cmake overhaul is in place
- PR #4094[2019] - Deprecate `HPX_WITH_MORE_THAN_64_THREADS`
- PR #4093[2020] - Fix initialization of `global_num_tasks` in `parallel_executor`
- PR #4092[2021] - Add support for mi-malloc
- PR #4090[2022] - Execution context
- PR #4089[2023] - Make counters in coroutines optional
- PR #4087[2024] - Making `hpx::util::any` compatible with C++17
- PR #4084[2025] - Making sure destination array for `std::transform` is properly resized
- PR #4083[2026] - Adapting `thread_queue_mc` to behave even if no 128bit atomics are available
- PR #4082[2027] - Fix compilation on GCC 5
- PR #4081[2028] - Adding option allowing to force using Boost.FileSystem
- PR #4080[2029] - Updating module dependencies

- PR #4079[2030] - Add missing tests for iterator_support module
- PR #4078[2031] - Disable parcel-layer if networking is disabled
- PR #4077[2032] - Add missing include that causes build fails
- PR #4076[2033] - Enable compatibility headers for functional module
- PR #4075[2034] - Coroutines module
- PR #4073[2035] - Use `configure_file` for generated files in modules
- PR #4071[2036] - Fixing MPI detection for PMIx
- PR #4070[2037] - Fix macOS builds
- PR #4069[2038] - Moving more facilities to the collectives module
- PR #4068[2039] - Adding main HPX `#include` directory to modules
- PR #4066[2040] - Switching the use of `message(STATUS "...")` to hpx_info
- PR #4065[2041] - Move Boost.Filesystem handling to filesystem module
- PR #4064[2042] - Fix program_options test with older boost versions
- PR #4062[2043] - The `cpu_features` tool fails to compile on anything but x86 architectures
- PR #4061[2044] - Add `clang-format` checking step for modules
- PR #4060[2045] - Making sure `HPX_IDLE_BACKOFF_TIME_MAX` is always defined (even if its unused)
- PR #4059[2046] - Renaming module `hpx_parallel_executors` into `hpx_execution`
- PR #4058[2047] - Do not build networking tests when networking disabled
- PR #4057[2048] - Printing configuration summary for modules as well
- PR #4055[2049] - Google Season of Docs updates to documentation; hpx build systems
- PR #4054[2050] - Add troubleshooting section to manual
- PR #4051[2051] - Add more variations to `future_overhead` test
- PR #4050[2052] - Creating plugin module

- PR #3927[2145] - Moving Cache module's tests into separate solution folder
- PR #3926[2146] - Move unit tests to cache module
- PR #3925[2147] - Move version check to config module
- PR #3924[2148] - Add schedule hint executor parameters
- PR #3923[2149] - Allow aligning objects bigger than the cache line size
- PR #3922[2150] - Add Windows builds with Travis CI
- PR #3921[2151] - Add ccls cache directory to gitignore
- PR #3920[2152] - Fix `git_external` fetching of tags
- PR #3905[2153] - Correct rostambod url. Fix typo in doc
- PR #3904[2154] - Fix bug in context_base.hpp
- PR #3903[2155] - Adding new performance counters
- PR #3902[2156] - Add `add_hpx_module` function
- PR #3901[2157] - Factoring out container remapping into a separate trait
- PR #3900[2158] - Making sure errors during command line processing are properly reported and will not cause assertions
- PR #3899[2159] - Remove old compatibility bases from `make_action`
- PR #3898[2160] - Make parameter size be of type `size_t`
- PR #3897[2161] - Making sure all tests are disabled if `HPX_WITH_TESTS=OFF`
- PR #3895[2162] - Add documentation for annotated_function
- PR #3894[2163] - Working around VS2019 problem with `make_action`
- PR #3892[2164] - Avoid MSVC compatibility warning in internal allocator
- PR #3891[2165] - Removal of the default intel config include
- PR #3888[2166] - Fix `async_customization` dataflow example and Clarify what's being tested
- PR #3887[2167] - Add Doxygen documentation

2.10.9 *HPX* V1.3.0 (May 23, 2019)

General changes

- Performance improvements: the schedulers have significantly reduced overheads from removing false sharing and the parallel executor has been updated to create fewer futures.
- HPX now defaults to not turning on networking when running on one locality. This means that you can run multiple instances on the same system without adding command line options.
- Multiple issues reported by Clang sanitizers have been fixed.
- We have added (back) single-page HTML documentation and PDF documentation.
- We have started modularizing the HPX library. This is useful both for developers and users. In the long term users will be able to consume only parts of the HPX libraries if they do not require all the functionality that HPX currently provides.
- We have added an implementation of `function_ref`.
- The `barrier` and `latch` classes have gained a few additional member functions.

Breaking changes

- Executable and library targets are now created without the `_exe` and `_lib` suffix respectively. For example, the target `1d_stencil_1_exe` is now simply called `1d_stencil_1`.
- We have removed the following deprecated functionality: `queue`, `scoped_unlock`, and support for input iterators in algorithms.
- We have turned off the compatibility layer for `unwrapped` by default. The functionality will be removed in the next release. The option can still be turned on using the CMake[2188] option `HPX_WITH_UNWRAPPED_SUPPORT`. Likewise, `inclusive_scan` compatibility overloads have been turned off by default. They can still be turned on with `HPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY`.
- The minimum compiler and dependency versions have been updated. We now support GCC from version 5 onwards, Clang from version 4 onwards, and Boost from version 1.61.0 onwards.
- The headers for preprocessor macros have moved as a result of the functionality being moved to a separate module. The old headers are deprecated and will be removed in a future version of HPX. You can turn off the warnings by setting `HPX_PREPROCESSOR_WITH_DEPRECATION_WARNINGS=OFF` or turn off the compatibility headers completely with `HPX_PREPROCESSOR_WITH_COMPATIBILITY_HEADERS=OFF`.

Closed issues

- Issue #3863[2189] - shouldn't "-faligned-new" be a usage requirement?
- Issue #3841[2190] - Build error with msvc 19 caused by SFINAE and C++17
- Issue #3836[2191] - master branch does not build with idle rate counters enabled
- Issue #3819[2192] - Add debug suffix to modules built in debug mode
- Issue #3817[2193] - `HPX_INCLUDE_DIRS` contains non-existent directory

- PR #3846[2262] - Add tests for libs header tests
- PR #3844[2263] - Fixing source_groups in preprocessor module to properly handle compatibility headers
- PR #3843[2264] - This fixes the launch_process/launched_process pair of tests
- PR #3842[2265] - Fix macro call with ITTNOTIFY enabled
- PR #3840[2266] - Fixing SLURM environment parsing
- PR #3837[2267] - Fixing misplaced #endif
- PR #3835[2268] - make all latch members protected for consistency
- PR #3834[2269] - Disable transpose_block_numa example on CircleCI
- PR #3833[2270] - make latch **counter_** protected for deriving latch in hpxmp
- PR #3831[2271] - Fix CircleCI config for modules
- PR #3830[2272] - minor fix: option HPX_WITH_TEST was not working correctly
- PR #3828[2273] - Avoid for binaries that depend on HPX to directly link against internal modules
- PR #3827[2274] - Adding shortcut for `hpx::get_ptr<>(sync, id)` for a local, non-migratable objects
- PR #3826[2275] - Fix and update modules documentation
- PR #3825[2276] - Updating default APEX version to 2.1.3 with HPX
- PR #3823[2277] - Fix pkgconfig libs handling
- PR #3822[2278] - Change includes in hpx_wrap.cpp to more specific includes
- PR #3821[2279] - Disable barrier_3792 test when networking is disabled
- PR #3820[2280] - Assorted CMake fixes
- PR #3815[2281] - Removing left-over debug output
- PR #3814[2282] - Allow setting default scheduler mode via the configuration database
- PR #3813[2283] - Make the deprecation warnings issued by the old pp headers optional
- PR #3812[2284] - Windows requires to handle symlinks to directories differently from those linking files

- PR #3811[2285] - Clean up PP module and library skeleton
- PR #3806[2286] - Moving include path configuration to before APEX
- PR #3804[2287] - Fix latch
- PR #3803[2288] - Update hpxcxx to look at lib64 and use python3
- PR #3802[2289] - Numa binding allocator
- PR #3801[2290] - Remove duplicated includes
- PR #3800[2291] - Attempt to fix Posix context switching after lazy init changes
- PR #3798[2292] - count and count_if accepts different iterator types
- PR #3797[2293] - Adding a couple of `override` keywords to overloaded virtual functions
- PR #3796[2294] - Re-enable testing all schedulers in shutdown_suspended_test
- PR #3795[2295] - Change `std::terminate` to std::abort in `SIGSEGV` handler
- PR #3794[2296] - Fixing #3792
- PR #3793[2297] - Extending migrate_polymorphic_component unit test
- PR #3791[2298] - Change `throw()` to `noexcept`
- PR #3790[2299] - Remove deprecated options for 1.3.0 release
- PR #3789[2300] - Remove Boost filesystem compatibility header
- PR #3788[2301] - Disabled even more spots that should not execute if networking is disabled
- PR #3787[2302] - Bump minimal boost supported version to 1.61.0
- PR #3786[2303] - Bump minimum required versions for 1.3.0 release
- PR #3785[2304] - Explicitly set number of jobs for all ninja invocations on CircleCI
- PR #3784[2305] - Fix leak and address sanitizer problems
- PR #3783[2306] - Disabled even more spots that should not execute is networking is disabled
- PR #3782[2307] - Cherry-picked tuple and thread_init_data fixes from #3701

- PR #3781[2308] - Fix generic context coroutines after lazy stack allocation changes
- PR #3780[2309] - Rename hello world examples
- PR #3776[2310] - Sort algorithms now use the supplied chunker to determine the required minimal chunk size
- PR #3775[2311] - Disable Boost auto-linking
- PR #3774[2312] - Tag and push stable builds
- PR #3773[2313] - Enable migration of polymorphic components
- PR #3771[2314] - Fix link to stackoverflow in documentation
- PR #3770[2315] - Replacing constexpr if in brace-serialization code
- PR #3769[2316] - Fix SIGSEGV handler
- PR #3768[2317] - Adding flags to scheduler allowing to control thread stealing and idle back-off
- PR #3767[2318] - Fix help formatting in hpxrun.py
- PR #3765[2319] - Fix a couple of bugs in the thread test
- PR #3764[2320] - Workaround for SFINAE regression in msvc14.2
- PR #3762[2321] - Prevent MSVC from prematurely instantiating things
- PR #3761[2322] - Update python scripts to work with python 3
- PR #3760[2323] - Fix callable vtable for GCC4.9
- PR #3759[2324] - Rename `PAGE_SIZE` to `PAGE_SIZE_` because AppleClang
- PR #3755[2325] - Making sure locks are not held during suspension
- PR #3754[2326] - Disable more code if networking is not available/not enabled
- PR #3752[2327] - Move `util::format` implementation to source file
- PR #3751[2328] - Fixing problems with `lcos::barrier` and iostreams
- PR #3750[2329] - Change error message to take into account `use_guard_page` setting
- PR #3749[2330] - Fix lifetime problem in `run_as_hpx_thread`

- PR #3748[2331] - Fixed unusable behavior of the clang code analyzer.
- PR #3747[2332] - Added `PMIX_RANK` to the defaults of `HPX_WITH_PARCELPORT_MPI_ENV`.
- PR #3745[2333] - Introduced `cache_aligned_data` and `cache_line_data` helper structure
- PR #3742[2334] - Remove more unused functionality from util/logging
- PR #3740[2335] - Fix includes in partitioned vector tests
- PR #3739[2336] - More fixes to make sure that `std::flush` really flushes all output
- PR #3737[2337] - Fix potential shutdown problems
- PR #3736[2338] - Fix `guided_pool_executor` after dataflow changes caused compilation fail
- PR #3734[2339] - Limiting executor
- PR #3732[2340] - More constrained bound constructors
- PR #3730[2341] - Attempt to fix deadlocks during component loading
- PR #3729[2342] - Add latch member function `count_up` and reset, requested by hpxMP
- PR #3728[2343] - Send even empty buffers on `hpx::endl` and `hpx::flush`
- PR #3727[2344] - Adding example demonstrating how to customize the memory management for a component
- PR #3726[2345] - Adding support for passing command line options through the `HPX_COMMANDLINE_OPTIONS` environment variable
- PR #3722[2346] - Document known broken OpenMPI builds
- PR #3716[2347] - Add barrier reset function, requested by hpxMP for reusing barrier
- PR #3715[2348] - More work on functions and vtables
- PR #3714[2349] - Generate single-page HTML, PDF, manpage from documentation
- PR #3713[2350] - Updating default APEX version to 2.1.2
- PR #3712[2351] - Update release procedure
- PR #3710[2352] - Fix the C++11 build, after #3704
- PR #3709[2353] - Move some component_registry functionality to source file

- PR #3708[2354] - Ignore all locks while handling assertions
- PR #3707[2355] - Remove obsolete hpx runtime executable
- PR #3705[2356] - Fix and simplify `make_ready_future` overload sets
- PR #3704[2357] - Reduce use of binders
- PR #3703[2358] - Ini
- PR #3702[2359] - Fixing CUDA compiler errors
- PR #3700[2360] - Added `barrier::increment` function to increase total number of thread
- PR #3697[2361] - One more attempt to fix migration…
- PR #3694[2362] - Fixing component migration
- PR #3693[2363] - Print thread state when getting disallowed value in set_thread_state
- PR #3692[2364] - Only disable `constexpr` with clang-cuda, not nvcc+gcc
- PR #3691[2365] - Link with libsupc++ if needed for thread_local
- PR #3690[2366] - Remove thousands separators in set_operations_3442 to comply with C++11
- PR #3688[2367] - Decouple serialization from function vtables
- PR #3687[2368] - Fix a couple of test failures
- PR #3686[2369] - Make sure tests.unit.build are run after install on CircleCI
- PR #3685[2370] - Revise quickstart CMakeLists.txt explanation
- PR #3684[2371] - Provide concept emulation for Ranges-TS concepts
- PR #3683[2372] - Ignore uninitialized chunks
- PR #3682[2373] - Ignore uninitialized chunks. Check proper indices.
- PR #3680[2374] - Ignore uninitialized chunks. Check proper range indices
- PR #3679[2375] - Simplify basic action implementations
- PR #3678[2376] - Making sure `HPX_HAVE_LIBATOMIC` is unset before checking

- PR #3677[2377] - Fix generated full version number to be usable in expressions
- PR #3674[2378] - Reduce functional utilities call depth
- PR #3672[2379] - Change new build system to use existing macros related to pseudo dependencies
- PR #3669[2380] - Remove indirection in `function_ref` when thread description is disabled
- PR #3668[2381] - Unbreaking `async_*cb*` tests
- PR #3667[2382] - Generate version.hpp
- PR #3665[2383] - Enabling MPI parcelport for gitlab runners
- PR #3664[2384] - making clang-tidy work properly again
- PR #3662[2385] - Attempt to fix exception handling
- PR #3661[2386] - Move `lcos::latch` to source file
- PR #3660[2387] - Fix accidentally explicit gid_type default constructor
- PR #3659[2388] - Parallel executor latch
- PR #3658[2389] - Fixing execution_parameters
- PR #3657[2390] - Avoid dangling references in wait_all
- PR #3656[2391] - Avoiding lifetime problems with sync_put_parcel
- PR #3655[2392] - Fixing nullptr dereference inside of function
- PR #3652[2393] - Attempt to fix `thread_map_type` definition with C++11
- PR #3650[2394] - Allowing for end iterator being different from begin iterator
- PR #3649[2395] - Added architecture identification to cmake to be able to detect timestamp support
- PR #3645[2396] - Enabling sanitizers on gitlab runner
- PR #3644[2397] - Attempt to tackle timeouts during startup
- PR #3642[2398] - Cleanup parallel partitioners
- PR #3640[2399] - Dataflow now works with functions that return a reference

- PR #3637[2400] - Merging the executor-enabled overloads of `shared_future<>::then`
- PR #3633[2401] - Replace deprecated boost endian macros
- PR #3632[2402] - Add instructions on getting HPX to documentation
- PR #3631[2403] - Simplify parcel creation
- PR #3630[2404] - Small additions and fixes to release procedure
- PR #3629[2405] - Modular pp
- PR #3627[2406] - Implement `util::function_ref`
- PR #3626[2407] - Fix cancelable_action_client example
- PR #3625[2408] - Added automatic serialization for simple structs (see #3034)
- PR #3624[2409] - Updating the default order of priority for `thread_description`
- PR #3621[2410] - Update copyright year and other small formatting fixes
- PR #3620[2411] - Adding support for gitlab runner
- PR #3619[2412] - Store debug logs and core dumps on CircleCI
- PR #3618[2413] - Various optimizations
- PR #3617[2414] - Fix link to the gpg key (#2)
- PR #3615[2415] - Fix unused variable warnings with networking off
- PR #3614[2416] - Restructuring counter data in scheduler to reduce false sharing
- PR #3613[2417] - Adding support for gitlab runners
- PR #3610[2418] - Don't wait for `stop_condition` in main thread
- PR #3608[2419] - Add inline keyword to `invalid_thread_id` definition for nvcc
- PR #3607[2420] - Adding configuration key that allows one to explicitly add a directory to the component search path
- PR #3606[2421] - Add nvcc to exclude constexpress since is it not supported by nvcc
- PR #3605[2422] - Add `inline` to definition of checkpoint stream operators to fix link error

2.10.10 *HPX* V1.2.1 (Feb 19, 2019)

General changes

This is a bugfix release. It contains the following changes:

- Fix compilation on ARM, s390x and 32-bit architectures.
- Fix a critical bug in the `future` implementation.
- Fix several problems in the CMake configuration which affects external projects.

2.10.11 *HPX* V1.2.0 (Nov 12, 2018)

General changes

Here are some of the main highlights and changes for this release:

- Thanks to the work of our Google Summer of Code student, Nikunj Gupta, we now have a new implementation of `hpx_main.hpp` on supported platforms (Linux, BSD and MacOS). This is intended to be a less fragile drop-in replacement for the old implementation relying on preprocessor macros. The new implementation does not require changes if you are using the CMake[2482] or pkg-config. The old behaviour can be restored by setting `HPX_WITH_DYNAMIC_HPX_MAIN=OFF` during CMake[2483] configuration. The implementation on Windows is unchanged.
- We have added functionality to allow passing scheduling hints to our schedulers. These will allow us to create executors that for example target a specific NUMA domain or allow for *HPX* threads to be pinned to a particular worker thread.
- We have significantly improved the performance of our futures implementation by making the shared state atomic.
- We have replaced Boostbook by Sphinx for our documentation. This means the documentation is easier to navigate with built-in search and table of contents. We have also added a quick start section and restructured the documentation to be easier to follow for new users.
- We have added a new option to the *`--hpx:threads`* command line option. It is now possible to use `cores` to tell *HPX* to only use one worker thread per core, unlike the existing option `all` which uses one worker thread per processing unit (processing unit can be a hyperthread if hyperthreads are available). The default value of *`--hpx:threads`* has also been changed to `cores` as this leads to better performance in most cases.
- All command line options can now be passed alongside configuration options when initializing *HPX*. This means that some options that were previously only available on the command line can now be set as configuration options.
- HPXMP is a portable, scalable, and flexible application programming interface using the OpenMP specification that supports multi-platform shared memory multiprocessing programming in C and C++. HPXMP can be enabled within *HPX* by setting `DHPX_WITH_HPXMP=ON` during CMake[2484] configuration.
- Two new performance counters were added for measuring the time spent doing background work. `/threads/time/background-work-duration` returns the time spent doing background on a given thread or locality, while `/threads/time/background-overhead` returns the fraction of time spent doing background work with respect to the overall time spent running the scheduler. The new performance counters are disabled by default and can be turned on by setting `HPX_WITH_BACKGROUND_THREAD_COUNTERS=ON` during CMake[2485] configuration.
- The idling behaviour of *HPX* has been tweaked to allow for faster idling. This is useful in interactive applications where the *HPX* worker threads may not have work all the time. This behaviour can be tweaked and turned off as before with `HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF=OFF` during CMake[2486] configuration.
- It is now possible to register callback functions for *HPX* worker thread events. Callbacks can be registered for starting and stopping worker threads, and for when errors occur.

Breaking changes

- The implementation of `hpx_main.hpp` has changed. If you are using custom Makefiles you will need to make changes. Please see the documentation on *using Makefiles* for more details.
- The default value of *`--hpx:threads`* has changed from `all` to `cores`. The new option `cores` only starts one worker thread per core.
- We have dropped support for Boost 1.56 and 1.57. The minimal version of Boost we now test is 1.58.
- Our `boost::format`-based formatting implementation has been revised and replaced with a custom implementation. This changes the formatting syntax and requires changes if you are relying on *`hpx::util::format`* or *`hpx::util::format_to`*. The pull request for this change contains more information: PR #3266[2487].
- The following deprecated options have now been completely removed: `HPX_WITH_ASYNC_FUNCTION_COMPATIBILITY`, `HPX_WITH_LOCAL_DATAFLOW`, `HPX_WITH_GENERIC_EXECUTION_POLICY`, `HPX_WITH_BOOST_CHRONO_COMPATIBILITY`, `HPX_WITH_EXECUTOR_COMPATIBILITY`, `HPX_WITH_EXECUTION_POLICY_COMPATIBILITY`, and `HPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY`.

Closed issues

- PR #3490[2569] - Don't create tasks immediately with hpx::apply
- PR #3489[2570] - Remove deprecated options for 1.2.0
- PR #3488[2571] - Revert "Use BUILD_INTERFACE generator expression to fix cmake flag exports"
- PR #3487[2572] - Revert "Fixing type attribute warning for transfer_action"
- PR #3485[2573] - Use BUILD_INTERFACE generator expression to fix cmake flag exports
- PR #3483[2574] - Fixing type attribute warning for transfer_action
- PR #3481[2575] - Remove unused variables
- PR #3480[2576] - Towards a more lightweight transfer action
- PR #3479[2577] - Fix FLAGS - Use correct version of target_compile_options
- PR #3478[2578] - Making sure the application's exit code is properly propagated back to the OS
- PR #3476[2579] - Don't print docker credentials as part of the environment.
- PR #3473[2580] - Fixing invalid cmake code if no jemalloc prefix was given
- PR #3472[2581] - Attempting to work around recent clang test compilation failures
- PR #3471[2582] - Enable jemalloc on windows
- PR #3470[2583] - Updates readme
- PR #3468[2584] - Avoid hang if there is an exception thrown during startup
- PR #3467[2585] - Add compiler specific fallthrough attributes if C++17 attribute is not available
- PR #3466[2586] - - bugfix : fix compilation with llvm-7.0
- PR #3465[2587] - This patch adds various optimizations extracted from the thread_local_allocator work
- PR #3464[2588] - Check for forked repos in CircleCI docker push step
- PR #3463[2589] - - cmake : create the parent directory before symlinking
- PR #3459[2590] - Remove unused/incomplete functionality from util/logging
- PR #3458[2591] - Fix a problem with scope of CMAKE_CXX_FLAGS and hpx_add_compile_flag

- PR #3457[2592] - Fixing more size_t -> int16_t (and similar) warnings
- PR #3456[2593] - Add #ifdefs to topology.cpp to support old hwloc versions again
- PR #3454[2594] - Fixing warnings related to silent conversion of size_t –> int16_t
- PR #3451[2595] - Add examples as unit tests
- PR #3450[2596] - Constexpr-fying bind and other functional facilities
- PR #3446[2597] - Fix some thread suspension timeouts
- PR #3445[2598] - Fix various warnings
- PR #3443[2599] - Only enable service pool config options if pools are enabled
- PR #3441[2600] - Fix missing closing brackets in documentation
- PR #3439[2601] - Use correct MPI CXX libraries for MPI parcelport
- PR #3436[2602] - Add projection function to find_* (and fix very bad bug)
- PR #3435[2603] - Fixing 1205
- PR #3434[2604] - Fix threads cores
- PR #3433[2605] - Add Heise Online to release announcement list
- PR #3432[2606] - Don't track task dependencies for distributed runs
- PR #3431[2607] - Circle CI setting changes for hpxMP
- PR #3430[2608] - Fix unused params warning
- PR #3429[2609] - One thread per core
- PR #3428[2610] - This suppresses a deprecation warning that is being issued by MSVC 19.15.26726
- PR #3427[2611] - Fixes #3426
- PR #3425[2612] - Use source cache and workspace between job steps on CircleCI
- PR #3421[2613] - Add CDash timing output to future overhead test (for graphs)
- PR #3420[2614] - Add guided_pool_executor

- PR #3389[2638] - Fix deadlock during shutdown
- PR #3388[2639] - Add several functionalities allowing to optimize synchronous action invocation
- PR #3387[2640] - Add cmake option to opt out of fail-compile tests
- PR #3386[2641] - Adding support for boost::container::small_vector to dataflow
- PR #3385[2642] - Adds Debug option for hpx initializing from main
- PR #3384[2643] - This hopefully fixes two tests that occasionally fail
- PR #3383[2644] - Making sure thread local storage is enable for hpxMP
- PR #3382[2645] - Fix usage of HPX_CAPTURE together with default value capture [=]
- PR #3381[2646] - Replace undefined instantiations of uniform_int_distribution
- PR #3380[2647] - Add missing semicolons to uses of HPX_COMPILER_FENCE
- PR #3379[2648] - Fixing #3378
- PR #3377[2649] - Adding build system support to integrate hpxmp into hpx at the user's machine
- PR #3375[2650] - Replacing wrapper for __libc_start_main with main
- PR #3374[2651] - Adds hpx_wrap to HPX_LINK_LIBRARIES which links only when specified.
- PR #3373[2652] - Forcing cache settings in HPXConfig.cmake to guarantee updated values
- PR #3372[2653] - Fix some more c++11 build problems
- PR #3371[2654] - Adds HPX_LINKER_FLAGS to HPX applications without editing their source codes
- PR #3370[2655] - util::format: add type_specifier<> specializations for %!s(MISSING) and %!l(MISSING)s
- PR #3369[2656] - Adding configuration option to allow explicit disable of the new hpx_main feature on Linux
- PR #3368[2657] - Updates doc with recent hpx_wrap implementation
- PR #3367[2658] - Adds Mac OS implementation to hpx_main.hpp
- PR #3365[2659] - Fix order of hpx libs in HPX_CONF_LIBRARIES.
- PR #3363[2660] - Apex fixing null wrapper

- PR #3328[2684] - Making sure object is pinned while executing actions, even if action returns a future
- PR #3327[2685] - Add missing std::forward to tuple.hpp
- PR #3326[2686] - Make sure logging is up and running while modules are being discovered.
- PR #3324[2687] - Replace C++14 overload of std::equal with C++11 code.
- PR #3323[2688] - Fix a missing apex thread data (wrapper) initialization
- PR #3320[2689] - Adding support for -std=c++2a (define *HPX_WITH_CXX2A=On*)
- PR #3319[2690] - Replacing C++14 feature with equivalent C++11 code
- PR #3317[2691] - Fix compilation with VS 15.7.1 and /std:c++latest
- PR #3316[2692] - Fix includes for 1d_stencil_*_omp examples
- PR #3314[2693] - Remove some unused parameter warnings
- PR #3313[2694] - Fix pu-step and pu-offset command line options
- PR #3312[2695] - Add conversion of inspect reports to JUnit XML
- PR #3311[2696] - Fix escaping of closing braces in format specification syntax
- PR #3310[2697] - Don't overwrite user settings with defaults in registration database
- PR #3309[2698] - Fixing potential stack overflow for dataflow
- PR #3308[2699] - This updates the .clang-format configuration file to utilize newer features
- PR #3306[2700] - Marking migratable objects in their gid to allow not handling migration in AGAS
- PR #3305[2701] - Add proper exception handling to run_as_hpx_thread
- PR #3303[2702] - Changed std::rand to a better inbuilt PRNG Generator
- PR #3302[2703] - All non-migratable (simple) components now encode their lva and component type in their gid

- PR #3036[2743] - Switching to CircleCI 2.0

2.10.12 *HPX* V1.1.0 (Mar 24, 2018)

General changes

Here are some of the main highlights and changes for this release (in no particular order):

- We have changed the way *HPX* manages the processing units on a node. We do not longer implicitly bind all available cores to a single thread pool. The user has now full control over what processing units are bound to what thread pool, each with a separate scheduler. It is now also possible to create your own scheduler implementation and control what processing units this scheduler should use. We added the `hpx::resource::partitioner` that manages all available processing units and assigns resources to the used thread pools. Thread pools can be now be suspended/resumed independently. This functionality helps in running *HPX* concurrently to code that is directly relying on OpenMP[2744] and/or MPI[2745].
- We have continued to implement various parallel algorithms. *HPX* now almost completely implements all of the parallel algorithms as specified by the C++17 Standard[2746]. We have also continued to implement these algorithms for the distributed use case (for segmented data structures, such as `hpx::partitioned_vector`).

- Added a compatibility layer for `std::thread`, `std::mutex`, and `std::condition_variable` allowing for the code to use those facilities where available and to fall back to the corresponding Boost facilities otherwise. The CMake[2747] configuration option `-DHPX_WITH_THREAD_COMPATIBILITY=On` can be used to force using the Boost equivalents.
- The parameter sequence for the `hpx::parallel::transform_inclusive_scan` overload taking one iterator range has changed (again) to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing `-DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake[2748].
- The parameter sequence for the `hpx::parallel::inclusive_scan` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing `-DHPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY=On` to CMake.
- Added a helper facility `hpx::local_new` which is equivalent to `hpx::new_` except that it creates components locally only. As a consequence, the used component constructor may accept non-serializable argument types and/or non-const references or pointers.
- Removed the (broken) component type `hpx::lcos::queue<T>`. The old type is still available at configure time by passing `-DHPX_WITH_QUEUE_COMPATIBILITY=On` to CMake.
- The parallel algorithms adopted for C++17 restrict the iterator categories usable with those to at least forward iterators. Our implementation of the parallel algorithms was supporting input iterators (and output iterators) as well by simply falling back to sequential execution. We have now made our implementations conforming by requiring at least forward iterators. In order to enable the old behavior use the compatibility option `-DHPX_WITH_ALGORITHM_INPUT_ITERATOR_SUPPORT=On` on the CMake[2749] command line.
- We have added the functionalities allowing for LCOs being implemented using (simple) components. Before LCOs had to always be implemented using managed components.
- User defined components don't have to be default-constructible anymore. Return types from actions don't have to be default-constructible anymore either. Our serialization layer now in general supports non-default-constructible types.
- We have added a new launch policy `hpx::launch::lazy` that allows oneto defer the decision on what launch policy to use to the point of execution. This policy is initialized with a function (object) that – when invoked – is expected to produce the desired launch policy.

Breaking changes

- We have dropped support for the gcc compiler version V4.8. The minimal gcc version we now test on is gcc V4.9. The minimally required version of CMake[2750] is now V3.3.2.
- We have dropped support for the Visual Studio 2013 compiler version. The minimal Visual Studio version we now test on is Visual Studio 2015.5.
- We have dropped support for the Boost V1.51-V1.54. The minimal version of Boost we now test is Boost V1.55.
- We have dropped support for the `hpx::util::unwrapped` API. `hpx::util::unwrapped` will stay functional to some degree, until it finally gets removed in a later version of HPX. The functional usage of `hpx::util::unwrapped` should be changed to the new `hpx::util::unwrapping` function whereas the immediate usage should be replaced to `hpx::util::unwrap`.

- The performance counter names referring to properties as exposed by the threading subsystem have changes as those now additionally have to specify the thread-pool. See the corresponding documentation for more details.
- The overloads of `hpx::async` that invoke an action do not perform implicit unwrapping of the returned future anymore in case the invoked function does return a future in the first place. In this case `hpx::async` now returns a `hpx::future<future<T>>` making its behavior conforming to its local counterpart.
- We have replaced the use of `boost::exception_ptr` in our APIs with the equivalent `std::exception_ptr`. Please change your codes accordingly. No compatibility settings are provided.
- We have removed the compatibility settings for `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` as their life-cycle has reached its end.
- We have removed the experimental thread schedulers hierarchy_scheduler, periodic_priority_scheduler and throttling_scheduler in an effort to clean up and consolidate our thread schedulers.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #3250[2751] - Apex refactoring with guids
- PR #3249[2752] - Updating People.qbk
- PR #3246[2753] - Assorted fixes for CUDA
- PR #3245[2754] - Apex refactoring with guids
- PR #3242[2755] - Modify task counting in thread_queue.hpp
- PR #3240[2756] - Fixed typos
- PR #3238[2757] - Readding accidentally removed std::abort
- PR #3237[2758] - Adding Pipeline example
- PR #3236[2759] - Fixing memory_block
- PR #3233[2760] - Make schedule_thread take suspended threads into account
- Issue #3226[2761] - memory_block is breaking, signaling SIGSEGV on a thread on creation and freeing
- PR #3225[2762] - Applying quick fix for hwloc-2.0
- Issue #3224[2763] - HPX counters crashing the application
- PR #3223[2764] - Fix returns when setting config entries
- Issue #3222[2765] - Errors linking libhpx.so

- Issue #3221[2766] - HPX on Mac OS X with HWLoc 2.0.0 fails to run
- PR #3216[2767] - Reorder a variadic array to satisfy VS 2017 15.6
- PR #3214[2768] - Changed prerequisites.qbk to avoid confusion while building boost
- PR #3213[2769] - Relax locks for thread suspension to avoid holding locks when yielding
- PR #3212[2770] - Fix check in sequenced_executor test
- PR #3211[2771] - Use preinit_array to set argc/argv in init_globally example
- PR #3210[2772] - Adapted parallel::{search | search_n} for Ranges TS (see #1668)
- PR #3209[2773] - Fix locking problems during shutdown
- Issue #3208[2774] - init_globally throwing a run-time error
- PR #3206[2775] - Addition of new arithmetic performance counter "Count"
- PR #3205[2776] - Fixing return type calculation for bulk_then_execute
- PR #3204[2777] - Changing std::rand() to a better inbuilt PRNG generator
- PR #3203[2778] - Resolving problems during shutdown for VS2015
- PR #3202[2779] - Making sure resource partitioner is not accessed if its not valid
- PR #3201[2780] - Fixing optional::swap
- Issue #3200[2781] - hpx::util::optional fails
- PR #3199[2782] - Fix sliding_semaphore test
- PR #3198[2783] - Set pre_main status before launching run_helper
- PR #3197[2784] - Update README.rst
- PR #3194[2785] - parallel::{fill|fill_n} updated for Ranges TS
- PR #3193[2786] - Updating Runtime.cpp by adding correct description of Performance counters during register
- PR #3191[2787] - Fix sliding_semaphore_2338 test
- PR #3190[2788] - Topology improvements

- PR #2979[2973] - Fixing integer overflows
- PR #2978[2974] - Implement parallel::inplace_merge
- Issue #2977[2975] - Make hwloc compulsory instead of optional
- PR #2976[2976] - Making sure client_base instance that registered the component does not unregister it when being destructed
- PR #2975[2977] - Change version of pulled APEX to master
- PR #2974[2978] - Fix domain not being freed at the end of scheduling loop
- PR #2973[2979] - Fix small typos
- PR #2972[2980] - Adding uintstd.h header
- PR #2971[2981] - Fall back to creating local components using local_new
- PR #2970[2982] - Improve is_tuple_like trait
- PR #2969[2983] - Fix HPX_WITH_MORE_THAN_64_THREADS default value
- PR #2968[2984] - Cleaning up dataflow overload set
- PR #2967[2985] - Make parallel::merge is stable. (Fix #2964.)
- PR #2966[2986] - Fixing a couple of held locks during exception handling
- PR #2965[2987] - Adding missing #include
- Issue #2964[2988] - parallel merge is not stable
- PR #2963[2989] - Making sure any function object passed to dataflow is released after being invoked
- PR #2962[2990] - Partially reverting #2891
- PR #2961[2991] - Attempt to fix the gcc 4.9 problem with the async pack traversal
- Issue #2959[2992] - Program terminates during error handling
- Issue #2958[2993] - HPX_PLAIN_ACTION breaks due to missing include
- PR #2957[2994] - Fixing errors generated by mixing different attribute syntaxes
- Issue #2956[2995] - Mixing attribute syntaxes leads to compiler errors

- Issue #2955[2996] - Fix OS-Thread throttling
- PR #2953[2997] - Making sure any hpx.os_threads=N supplied through a –hpx::config file is taken into account
- PR #2952[2998] - Removing wrong call to cleanup_terminated_locked
- PR #2951[2999] - Revert "Make sure the function vtables are initialized before use"
- PR #2950[3000] - Fix a namespace compilation error when some schedulers are disabled
- Issue #2949[3001] - master branch giving lockups on shutdown
- Issue #2947[3002] - hpx.ini is not used correctly at initialization
- PR #2946[3003] - Adding explicit feature test for thread_local
- PR #2945[3004] - Make sure the function vtables are initialized before use
- PR #2944[3005] - Attempting to solve affinity problems on CircleCI
- PR #2943[3006] - Changing channel actions to be direct
- PR #2942[3007] - Adding split_future for std::vector
- PR #2941[3008] - Add a feature test to test for CXX11 override
- Issue #2940[3009] - Add split_future for future<vector<T>>
- PR #2939[3010] - Making error reporting during problems with setting affinity masks more verbose
- PR #2938[3011] - Fix this various executors
- PR #2937[3012] - Fix some typos in documentation
- PR #2934[3013] - Remove the need for "complete" SFINAE checks
- PR #2933[3014] - Making sure parallel::for_loop is executed in parallel if requested
- PR #2932[3015] - Classify chunk_size_iterator to input iterator tag. (Fix #2866)
- Issue #2931[3016] - –hpx:help triggers unusual error with clang build
- PR #2930[3017] - Add #include files needed to set _POSIX_VERSION for debug check
- PR #2929[3018] - Fix a couple of deprecated c++ features

- Issue #2831[3110] - `parallel/executors/execution_fwd.hpp` causes compilation failure in C++11 mode.
- PR #2829[3111] - Implement an API for asynchronous pack traversal
- PR #2828[3112] - Split unit test builds on CircleCI to avoid timeouts
- Issue #2827[3113] - failure to compile hello_world example with -Werror
- PR #2824[3114] - Making sure promises are marked as started when used as continuations
- PR #2823[3115] - Add documentation for partitioned_vector_view
- Issue #2822[3116] - Yet another issue with wait_for similar to #2796
- PR #2821[3117] - Fix bugs and improve that about HPX_HAVE_CXX11_AUTO_RETURN_VALUE of CMake
- PR #2820[3118] - Support C++11 in benchmark codes of parallel::partition and parallel::partition_copy
- PR #2819[3119] - Fix compile errors in unit test of container version of parallel::partition
- Issue #2818[3120] - A strange thing in parallel::util::detail::handle_local_exceptions
- Issue #2815[3121] - HPX fails to compile with HPX_WITH_CUDA=ON and the new CUDA 9.0 RC
- Issue #2814[3122] - Using 'gmakeN' after 'cmake' produces error in src/CMakeFiles/hpx.dir/runtime/agas/addressing_service.cpp.o
- PR #2813[3123] - Properly support [[noreturn]] attribute if available
- Issue #2812[3124] - Compilation fails with gcc 7.1.1
- PR #2811[3125] - Adding hpx::launch::lazy and support for async, dataflow, and future::then
- PR #2810[3126] - Add option allowing to disable deprecation warning
- PR #2809[3127] - Disable throttling scheduler if HWLOC is not found/used
- PR #2808[3128] - Fix compile errors on some environments of parallel::partition
- Issue #2807[3129] - Difficulty building with `HPX_WITH_HWLOC=Off`
- PR #2806[3130] - Partitioned vector
- PR #2805[3131] - Serializing collections with non-default constructible data

- PR #2656[3270] - Reduce MAX_TERMINATED_THREADS default, improve memory use on manycore cpus
- PR #2655[3271] - Mainteinance for emulate-deleted macros
- PR #2654[3272] - Implement parallel is_heap and is_heap_until
- PR #2653[3273] - Drop support for VS2013
- PR #2652[3274] - This patch makes sure that all parcels in a batch are properly handled
- PR #2649[3275] - Update docs (Table 18) - move transform to end
- Issue #2647[3276] - hpx::parcelset::detail::parcel_data::**has_continuation_** is uninitialized
- Issue #2644[3277] - Some .vcxproj in the HPX.sln fail to build
- Issue #2641[3278] - `hpx::lcos::queue` should be deprecated
- PR #2640[3279] - A new throttling policy with public APIs to suspend/resume
- PR #2639[3280] - Fix a tiny typo in tutorial.
- Issue #2638[3281] - Invalid return type 'void' of constexpr function
- PR #2636[3282] - Add and use HPX_MSVC_WARNING_PRAGMA for #pragma warning
- PR #2633[3283] - Distributed define_spmd_block
- PR #2632[3284] - Making sure container serialization uses size-compatible types
- PR #2631[3285] - Add lcos::local::one_element_channel
- PR #2629[3286] - Move unordered_map out of parcelport into hpx/concurrent
- PR #2628[3287] - Making sure that shutdown does not hang
- PR #2627[3288] - Fix serialization
- PR #2626[3289] - Generate `cmake_variables.qbk` and `cmake_toolchains.qbk` outside of the source tree
- PR #2625[3290] - Supporting -std=c++17 flag
- PR #2624[3291] - Fixing a small cmake typo
- PR #2622[3292] - Update CMake minimum required version to 3.0.2 (closes #2621)

2.10.13 *HPX* V1.0.0 (Apr 24, 2017)

General changes

Here are some of the main highlights and changes for this release (in no particular order):

- Added the facility `hpx::split_future` which allows one to convert a `future<tuple<Ts...>>` into a `tuple<future<Ts>...>`. This functionality is not available when compiling *HPX* with VS2012.
- Added a new type of performance counter which allows one to return a list of values for each invocation. We also added a first counter of this type which collects a histogram of the times between parcels being created.
- Added new LCOs: `hpx::lcos::channel` and `hpx::lcos::local::channel` which are very similar to the well known channel constructs used in the Go language.
- Added new performance counters reporting the amount of data handled by the networking layer on a action-by-action basis (please see PR #2289[3360] for more details).
- Added a new facility `hpx::lcos::barrier`, replacing the equally named older one. The new facility has a slightly changed API and is much more efficient. Most notable, the new facility exposes a (global) function `hpx::lcos::barrier::synchronize()` which represents a global barrier across all localities.
- We have started to add support for vectorization to our parallel algorithm implementations. This support depends on using an external library, currently either Vc Library or **|boost_simd|**_. Please see Issue #2333[3361] for a list of currently supported algorithms. This is an experimental feature and its implementation and/or API might change in the future. Please see this blog-post[3362] for more information.
- The parameter sequence for the `hpx::parallel::transform_reduce` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overload can be still enabled at configure time by specifying `-DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake.
- The algorithm `hpx::parallel::inner_product` has been renamed to `hpx::parallel::transform_reduce` to match the changes this algorithm has undergone while being moved to C++17. The old inner_product names can be still enabled at configure time by specifying `-DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake.
- Added versions of `hpx::get_ptr` taking client side representations for component instances as their parameter (instead of a global id).
- Added the helper utility `hpx::performance_counters::performance_counter_set` helping to encapsulate a set of performance counters to be managed concurrently.
- All execution policies and related classes have been renamed to be consistent with the naming changes applied for C++17. All policies now live in the namespace `hpx::parallel::execution`. The ols names can be still enabled at configure time by specifying `-DHPX_WITH_EXECUTION_POLICY_COMPATIBILITY=On` to CMake.
- The thread scheduling subsystem has undergone a major refactoring which results in significant performance improvements. We have also imroved the performance of creating `hpx::future` and of various facilities handling those.
- We have consolidated all of the code in HPX.Compute related to the integration of CUDA. `hpx::partitioned_vector` has been enabled to be usable with `hpx::compute::vector` which allows one to place the partitions on one or more GPU devices.
- Added new performance counters exposing various internals of the thread scheduling subsystem, such as the current idle- and busy-loop counters and instantaneous scheduler utilization.

[3360] https://github.com/STEllAR-GROUP/hpx/pull/2289
[3361] https://github.com/STEllAR-GROUP/hpx/issues/2333
[3362] http://stellar-group.org/2016/09/vectorized-cpp-parallel-algorithms-with-hpx/

- Extended and improved the use of the ITTNotify hooks allowing to collect performance counter data and function annotation information from within the Intel Amplifier tool.

Breaking changes

- We have dropped support for the gcc compiler versions V4.6 and 4.7. The minimal gcc version we now test on is gcc V4.8.
- We have removed (default) support for `boost::chrono` in interfaces, uses of it have been replaced with `std::chrono`. This facility can be still enabled at configure time by specifying `-DHPX_WITH_BOOST_CHRONO_COMPATIBILITY=On` to CMake.
- The parameter sequence for the `hpx::parallel::transform_reduce` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17.
- The algorithm `hpx::parallel::inner_product` has been renamed to `hpx::parallel::transform_reduce` to match the changes this algorithm has undergone while being moved to C++17.
- the build options `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` are now disabled by default. Please change your code still depending on the deprecated interfaces.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #2596[3363] - Adding apex data
- PR #2595[3364] - Remove obsolete file
- Issue #2594[3365] - FindOpenCL.cmake mismatch with the official cmake module
- PR #2592[3366] - First attempt to introduce spmd_block in hpx
- Issue #2591[3367] - Feature request: continuation (then) which does not require the callable object to take a future<R> as parameter
- PR #2588[3368] - Daint fixes
- PR #2587[3369] - Fixing transfer_(continuation)_action::schedule
- PR #2585[3370] - Work around MSVC having an ICE when compiling with -Ob2
- PR #2583[3371] - changing 7zip command to 7za in roll_release.sh
- PR #2582[3372] - First attempt to introduce spmd_block in hpx
- PR #2581[3373] - Enable annotated function for parallel algorithms

- PR #2553[3397] - Add cmake cuda_arch option
- PR #2552[3398] - Remove incomplete datapar bindings to libflatarray
- PR #2551[3399] - Rename hwloc_topology to hwloc_topology_info
- PR #2550[3400] - Apex api updates
- PR #2549[3401] - Pre-include defines.hpp to get the macro HPX_HAVE_CUDA value
- PR #2548[3402] - Fixing issue with disconnect
- PR #2546[3403] - Some fixes around cuda clang partitioned_vector example
- PR #2545[3404] - Fix uses of the Vc2 datapar flags; the value, not the type, should be passed to functions
- PR #2542[3405] - Make HPX_WITH_MALLOC easier to use
- PR #2541[3406] - avoid recompiles when enabling/disabling examples
- PR #2540[3407] - Fixing usage of target_link_libraries()
- PR #2539[3408] - fix RPATH behaviour
- Issue #2538[3409] - HPX_WITH_CUDA corrupts compilation flags
- PR #2537[3410] - Add output of a Bazel Skylark extension for paths and compile options
- PR #2536[3411] - Add counter exposing total available memory to Windows as well
- PR #2535[3412] - Remove obsolete support for security
- Issue #2534[3413] - Remove command line option `--hpx:run-agas-server`
- PR #2533[3414] - Pre-cache locality endpoints during bootstrap
- PR #2532[3415] - Fixing handling of GIDs during serialization preprocessing
- PR #2531[3416] - Amend uses of the term "functor"
- PR #2529[3417] - added counter for reading available memory
- PR #2527[3418] - Facilities to create actions from lambdas
- PR #2526[3419] - Updated docs: HPX_WITH_EXAMPLES

- PR #2525[3420] - Remove warnings related to unused captured variables
- Issue #2524[3421] - CMAKE failed because it is missing: TCMALLOC_LIBRARY TCMALLOC_INCLUDE_DIR
- PR #2523[3422] - Fixing compose_cb stack overflow
- PR #2522[3423] - Instead of unlocking, ignore the lock while creating the message handler
- PR #2521[3424] - Create `LPROGRESS_` logging macro to simplify progress tracking and timings
- PR #2520[3425] - Intel 17 support
- PR #2519[3426] - Fix components example
- PR #2518[3427] - Fixing parcel scheduling
- Issue #2517[3428] - Race condition during Parcel Coalescing Handler creation
- Issue #2516[3429] - HPX locks up when using at least 256 localities
- Issue #2515[3430] - error: Install cannot find "/lib/hpx/libparcel_coalescing.so.0.9.99" but I can see that file
- PR #2514[3431] - Making sure that all continuations of a shared_future are invoked in order
- PR #2513[3432] - Fixing locks held during suspension
- PR #2512[3433] - MPI Parcelport improvements and fixes related to the background work changes
- PR #2511[3434] - Fixing bit-wise (zero-copy) serialization
- Issue #2509[3435] - Linking errors in hwloc_topology
- PR #2508[3436] - Added documentation for debugging with core files
- PR #2506[3437] - Fixing background work invocations
- PR #2505[3438] - Fix tuple serialization
- Issue #2504[3439] - Ensure continuations are called in the order they have been attached
- PR #2503[3440] - Adding serialization support for Vc v2 (datapar)
- PR #2502[3441] - Resolve various, minor compiler warnings
- PR #2501[3442] - Some other fixes around cuda examples

- Issue #2500[3443] - nvcc / cuda clang issue due to a missing -DHPX_WITH_CUDA flag
- PR #2499[3444] - Adding support for std::array to wait_all and friends
- PR #2498[3445] - Execute background work as HPX thread
- PR #2497[3446] - Fixing configuration options for spinlock-deadlock detection
- PR #2496[3447] - Accounting for different compilers in CrayKNL toolchain file
- PR #2494[3448] - Adding component base class which ties a component instance to a given executor
- PR #2493[3449] - Enable controlling amount of pending threads which must be available to allow thread stealing
- PR #2492[3450] - Adding new command line option –hpx:print-counter-reset
- PR #2491[3451] - Resolve ambiguities when compiling with APEX
- PR #2490[3452] - Resuming threads waiting on future with higher priority
- Issue #2489[3453] - nvcc issue because -std=c++11 appears twice
- PR #2488[3454] - Adding performance counters exposing the internal idle and busy-loop counters
- PR #2487[3455] - Allowing for plain suspend to reschedule thread right away
- PR #2486[3456] - Only flag HPX code for CUDA if HPX_WITH_CUDA is set
- PR #2485[3457] - Making thread-queue parameters runtime-configurable
- PR #2484[3458] - Added atomic counter for parcel-destinations
- PR #2483[3459] - Added priority-queue lifo scheduler
- PR #2482[3460] - Changing scheduler to steal only if more than a minimal number of tasks are available
- PR #2481[3461] - Extending command line option –hpx:print-counter-destination to support value 'none'
- PR #2479[3462] - Added option to disable signal handler
- PR #2478[3463] - Making sure the sine performance counter module gets loaded only for the corresponding example
- Issue #2477[3464] - Breaking at a throw statement
- PR #2476[3465] - Annotated function

- Issue #1125[3680] - Fix the IPC parcelport
- Issue #839[3681] - Refactor ibverbs and shmem parcelport
- Issue #702[3682] - Add instrumentation of parcel layer
- Issue #668[3683] - Implement ispc task interface
- Issue #533[3684] - Thread queue/deque internal parameters should be runtime configurable
- Issue #475[3685] - Create a means of combining performance counters into querysets

2.10.14 *HPX* V0.9.99 (Jul 15, 2016)

General changes

As the version number of this release hints, we consider this release to be a preview for the upcoming *HPX* V1.0. All of the functionalities we set out to implement for V1.0 are in place; all of the features we wanted to have exposed are ready. We are very happy with the stability and performance of *HPX* and we would like to present this release to the community in order for us to gather broad feedback before releasing V1.0. We still expect for some minor details to change, but on the whole this release represents what we would like to have in a V1.0.

Overall, since the last release we have had almost 1600 commits while closing almost 400 tickets. These numbers reflect the incredible development activity we have seen over the last couple of months. We would like to express a big 'Thank you!' to all contributors and those who helped to make this release happen.

The most notable addition in terms of new functionality available with this release is the full implementation of object migration (i.e. the ability to transparently move *HPX* components to a different compute node). Additionally, this release of *HPX* cleans up many minor issues and some API inconsistencies.

Here are some of the main highlights and changes for this release (in no particular order):

- We have fixed a couple of issues in AGAS and the parcel layer which have caused hangs, segmentation faults at exit, and a slowdown of applications over time. Fixing those has significantly increased the overall stability and performance of distributed runs.

- We have started to add parallel algorithm overloads based on the C++ Extensions for Ranges (N4560[3686]) proposal. This also includes the addition of projections to the existing algorithms. Please see Issue #1668[3687] for a list of algorithms which have been adapted to N4560[3688].
- We have implemented index-based parallel for-loops based on a corresponding standardization proposal (P0075R1[3689]). Please see Issue #2016[3690] for a list of available algorithms.
- We have added implementations for more parallel algorithms as proposed for the upcoming C++ 17 Standard. See Issue #1141[3691] for an overview of which algorithms are available by now.
- We have started to implement a new prototypical functionality with *HPX.Compute* which uniformly exposes some of the higher level APIs to heterogeneous architectures (currently CUDA). This functionality is an early preview and should not be considered stable. It may change considerably in the future.
- We have pervasively added (optional) executor arguments to all API functions which schedule new work. Executors are now used throughout the code base as the main means of executing tasks.
- Added `hpx::make_future<R>(future<T> &&)` allowing to convert a future of any type `T` into a future of any other type `R`, either based on default conversion rules of the embedded types or using a given explicit conversion function.
- We finally finished the implementation of transparent migration of components to another locality. It is now possible to trigger a migration operation without 'stopping the world' for the object to migrate. *HPX* will make sure that no work is being performed on an object before it is migrated and that all subsequently scheduled work for the migrated object will be transparently forwarded to the new locality. Please note that the global id of the migrated object does not change, thus the application will not have to be changed in any way to support this new functionality. Please note that this feature is currently considered experimental. See Issue #559[3692] and PR #1966[3693] for more details.
- The `hpx::dataflow` facility is now usable with actions. Similarly to `hpx::async`, actions can be specified as an explicit template argument (`hpx::dataflow<Action>(target, ...)`) or as the first argument (`hpx::dataflow(Action(), target, ...)`). We have also enabled the use of distribution policies as the target for dataflow invocations. Please see Issue #1265[3694] and PR #1912[3695] for more information.
- Adding overloads of `gather_here` and `gather_there` to accept the plain values of the data to gather (in addition to the existing overloads expecting futures).
- We have cleaned up and refactored large parts of the code base. This helped reducing compile and link times of *HPX* itself and also of applications depending on it. We have further decreased the dependency of *HPX* on the Boost libraries by replacing part of those with facilities available from the standard libraries.
- Wherever possible we have removed dependencies of our API on Boost by replacing those with the equivalent facility from the C++11 standard library.
- We have added new performance counters for parcel coalescing, file-IO, the AGAS cache, and overall scheduler time. Resetting performance counters has been overhauled and fixed.
- We have introduced a generic client type `hpx::components::client<>` and added support for using it with `hpx::async`. This removes the necessity to implement specific client types for every component type without losing type safety. This deemphasizes the need for using the low level `hpx::id_type` for referencing

[3695] https://github.com/STEllAR-GROUP/hpx/pull/1912

(possibly remote) component instances. The plan is to deprecate the direct use of `hpx::id_type` in user code in the future.

- We have added a special iterator which supports automatic prefetching of one or more arrays for speeding up loop-like code (see `hpx::parallel::util::make_prefetcher_context()`).
- We have extended the interfaces exposed from executors (as proposed by N4406[3696]) to accept an arbitrary number of arguments.

Breaking changes

- In order to move the dataflow facility to `namespace hpx` we added a definition of `hpx::dataflow` which might create ambiguities in existing codes. The previous definition of this facility (`hpx::lcos::local::dataflow`) has been deprecated and is available only if the constant `-DHPX_WITH_LOCAL_DATAFLOW_COMPATIBILITY=On` to CMake[3697] is defined at configuration time. Please explicitly qualify all uses of the dataflow facility if you enable this compatibility setting and encounter ambiguities.
- The adaptation of the C++ Extensions for Ranges (N4560[3698]) proposal imposes some breaking changes related to the return types of some of the parallel algorithms. Please see Issue #1668[3699] for a list of algorithms which have already been adapted.
- The facility `hpx::lcos::make_future_void()` has been replaced by `hpx::make_future<void>()`.
- We have removed support for Intel V13 and gcc 4.4.x.
- We have removed (default) support for the generic `hpx::parallel::execution_poliy` because it was removed from the Parallelism TS (__cpp11_n4104__) while it was being added to the upcoming C++17 Standard. This facility can be still enabled at configure time by specifying `-DHPX_WITH_GENERIC_EXECUTION_POLICY=On` to CMake.
- Uses of `boost::shared_ptr` and related facilities have been replaced with `std::shared_ptr` and friends. Uses of `boost::unique_lock`, `boost::lock_guard` etc. have also been replaced by the equivalent (and equally named) tools available from the C++11 standard library.
- Facilities that used to expect an explicit `boost::unique_lock` now take an `std::unique_lock`. Additionally, `condition_variable` no longer aliases `condition_variable_any`; its interface now only works with `std::unique_lock<local::mutex>`.
- Uses of `boost::function`, `boost::bind`, `boost::tuple` have been replaced by the corresponding facilities in *HPX* (`hpx::util::function`, `hpx::util::bind`, and `hpx::util::tuple`, respectively).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #2250[3700] - change default chunker of parallel executor to static one
- PR #2247[3701] - HPX on ppc64le
- PR #2244[3702] - Fixing MSVC problems
- PR #2238[3703] - Fixing small typos
- PR #2237[3704] - Fixing small typos
- PR #2234[3705] - Fix broken add test macro when extra args are passed in
- PR #2231[3706] - Fixing possible race during future awaiting in serialization
- PR #2230[3707] - Fix stream nvcc
- PR #2229[3708] - Fixed run_as_hpx_thread
- PR #2228[3709] - On prefetching_test branch : adding prefetching_iterator and related tests used for prefetching containers within lambda functions
- PR #2227[3710] - Support for HPXCL's opencl::event
- PR #2226[3711] - Preparing for release of V0.9.99
- PR #2225[3712] - fix issue when compiling components with hpxcxx
- PR #2224[3713] - Compute alloc fix
- PR #2223[3714] - Simplify promise
- PR #2222[3715] - Replace last uses of boost::function by util::function_nonser
- PR #2221[3716] - Fix config tests
- PR #2220[3717] - Fixing gcc 4.6 compilation issues
- PR #2219[3718] - nullptr support for `[unique_]function`
- PR #2218[3719] - Introducing clang tidy
- PR #2216[3720] - Replace NULL with nullptr

- Issue #2214[3721] - Let inspect flag use of NULL, suggest nullptr instead
- PR #2213[3722] - Require support for nullptr
- PR #2212[3723] - Properly find jemalloc through pkg-config
- PR #2211[3724] - Disable a couple of warnings reported by Intel on Windows
- PR #2210[3725] - Fixed host::block_allocator::bulk_construct
- PR #2209[3726] - Started to clean up new sort algorithms, made things compile for sort_by_key
- PR #2208[3727] - A couple of fixes that were exposed by a new sort algorithm
- PR #2207[3728] - Adding missing includes in /hpx/include/serialization.hpp
- PR #2206[3729] - Call package_action::get_future before package_action::apply
- PR #2205[3730] - The indirect_packaged_task::operator() needs to be run on a HPX thread
- PR #2204[3731] - Variadic executor parameters
- PR #2203[3732] - Delay-initialize members of partitioned iterator
- PR #2202[3733] - Added segmented fill for hpx::vector
- Issue #2201[3734] - Null Thread id encountered on partitioned_vector
- PR #2200[3735] - Fix hangs
- PR #2199[3736] - Deprecating hpx/traits.hpp
- PR #2198[3737] - Making explicit inclusion of external libraries into build
- PR #2197[3738] - Fix typo in QT CMakeLists
- PR #2196[3739] - Fixing a gcc warning about attributes being ignored
- PR #2194[3740] - Fixing partitioned_vector_spmd_foreach example
- Issue #2193[3741] - partitioned_vector_spmd_foreach seg faults
- PR #2192[3742] - Support Boost.Thread v4
- PR #2191[3743] - HPX.Compute prototype

[3812] https://github.com/STEllAR-GROUP/hpx/pull/2115

- PR #2114[3813] - Adding hook functions for executor_parameter_traits supporting timers
- Issue #2113[3814] - Compilation error with gcc version 4.9.3 (MacPorts gcc49 4.9.3_0)
- PR #2112[3815] - Replace uses of safe_bool with explicit operator bool
- Issue #2111[3816] - Compilation error on QT example
- Issue #2110[3817] - Compilation error when passing non-future argument to unwrapped continuation in dataflow
- Issue #2109[3818] - Warning while compiling hpx
- Issue #2109[3819] - Stack trace of last bug causing issues with octotiger
- Issue #2108[3820] - Stack trace of last bug causing issues with octotiger
- PR #2107[3821] - Making sure that a missing parcel_coalescing module does not cause startup exceptions
- PR #2106[3822] - Stop using hpx_fwd.hpp
- Issue #2105[3823] - coalescing plugin handler is not optional any more
- Issue #2104[3824] - Make executor_traits N-nary
- Issue #2103[3825] - Build error with octotiger and hpx commit e657426d
- PR #2102[3826] - Combining thread data storage
- PR #2101[3827] - Added repartition version of 1d stencil that uses any performance counter
- PR #2100[3828] - Drop obsolete TR1 result_of protocol
- PR #2099[3829] - Replace uses of boost::bind with util::bind
- PR #2098[3830] - Deprecated inspect checks
- PR #2097[3831] - Reduce by key, extends #1141
- PR #2096[3832] - Moving local cache from external to hpx/util
- PR #2095[3833] - Bump minimum required Boost to 1.50.0
- PR #2094[3834] - Add include checks for several Boost utilities
- Issue #2093[3835] - /. . . /local_cache.hpp(89): error #303: explicit type is missing (“int” assumed)

- PR #2091[3836] - Fix for Raspberry pi build
- PR #2090[3837] - Fix storage size for util::function<>
- PR #2089[3838] - Fix #2088
- Issue #2088[3839] - More verbose output from cmake configuration
- PR #2087[3840] - Making sure init_globally always executes hpx_main
- Issue #2086[3841] - Race condition with recent HPX
- PR #2085[3842] - Adding #include checker
- PR #2084[3843] - Replace boost lock types with standard library ones
- PR #2083[3844] - Simplify packaged task
- PR #2082[3845] - Updating APEX version for testing
- PR #2081[3846] - Cleanup exception headers
- PR #2080[3847] - Make call_once variadic
- Issue #2079[3848] - With GNU C++, line 85 of hpx/config/version.hpp causes link failure when linking application
- Issue #2078[3849] - Simple test fails with _GLIBCXX_DEBUG defined
- PR #2077[3850] - Instantiate board in nqueen client
- PR #2076[3851] - Moving coalescing registration to TUs
- PR #2075[3852] - Fixed some documentation typos
- PR #2074[3853] - Adding flush-mode to message handler flush
- PR #2073[3854] - Fixing performance regression introduced lately
- PR #2072[3855] - Refactor local::condition_variable
- PR #2071[3856] - Timer based on boost::asio::deadline_timer
- PR #2070[3857] - Refactor tuple based functionality
- PR #2069[3858] - Fixed typos

- Issue #2068[3859] - Seg fault with octotiger
- PR #2067[3860] - Algorithm cleanup
- PR #2066[3861] - Split credit fixes
- PR #2065[3862] - Rename HPX_MOVABLE_BUT_NOT_COPYABLE to HPX_MOVABLE_ONLY
- PR #2064[3863] - Fixed some typos in docs
- PR #2063[3864] - Adding example demonstrating template components
- Issue #2062[3865] - Support component templates
- PR #2061[3866] - Replace some uses of lexical_cast<string> with C++11 std::to_string
- PR #2060[3867] - Replace uses of boost::noncopyable with HPX_NON_COPYABLE
- PR #2059[3868] - Adding missing for_loop algorithms
- PR #2058[3869] - Move several definitions to more appropriate headers
- PR #2057[3870] - Simplify assert_owns_lock and ignore_while_checking
- PR #2056[3871] - Replacing std::result_of with util::result_of
- PR #2055[3872] - Fix process launching/connecting back
- PR #2054[3873] - Add a forwarding coroutine header
- PR #2053[3874] - Replace uses of boost::unordered_map with std::unordered_map
- PR #2052[3875] - Rewrite tuple unwrap
- PR #2050[3876] - Replace uses of BOOST_SCOPED_ENUM with C++11 scoped enums
- PR #2049[3877] - Attempt to narrow down split_credit problem
- PR #2048[3878] - Fixing gcc startup hangs
- PR #2047[3879] - Fixing when_xxx and wait_xxx for MSVC12
- PR #2046[3880] - adding persistent_auto_chunk_size and related tests for for_each
- PR #2045[3881] - Fixing HPX_HAVE_THREAD_BACKTRACE_DEPTH build time configuration

- PR #2044[3882] - Adding missing service executor types
- PR #2043[3883] - Removing ambiguous definitions for is_future_range and future_range_traits
- PR #2042[3884] - Clarify that HPX builds can use (much) more than 2GB per process
- PR #2041[3885] - Changing future_iterator_traits to support pointers
- Issue #2040[3886] - Improve documentation memory usage warning?
- PR #2039[3887] - Coroutine cleanup
- PR #2038[3888] - Fix cmake policy CMP0042 warning MACOSX_RPATH
- PR #2037[3889] - Avoid redundant specialization of [**unique_**]function_nonser
- PR #2036[3890] - nvcc dies with an internal error upon pushing/popping warnings inside templates
- Issue #2035[3891] - Use a less restrictive iterator definition in hpx::lcos::detail::future_iterator_traits
- PR #2034[3892] - Fixing compilation error with thread queue wait time performance counter
- Issue #2033[3893] - Compilation error when compiling with thread queue waittime performance counter
- Issue #2032[3894] - Ambiguous template instantiation for is_future_range and future_range_traits.
- PR #2031[3895] - Don't restart timer on every incoming parcel
- PR #2030[3896] - Unify handling of execution policies in parallel algorithms
- PR #2029[3897] - Make pkg-config .pc files use .dylib on OSX
- PR #2028[3898] - Adding process component
- PR #2027[3899] - Making check for compiler compatibility independent on compiler path
- PR #2025[3900] - Fixing inspect tool
- PR #2024[3901] - Intel13 removal
- PR #2023[3902] - Fix errors related to older boost versions and parameter pack expansions in lambdas
- Issue #2022[3903] - gmake fail: "No rule to make target /usr/lib46/libboost_context-mt.so"
- PR #2021[3904] - Added Sudoku example

- Issue #2020[3905] - Make errors related to init_globally.cpp example while building HPX out of the box
- PR #2019[3906] - Fixed some compilation and cmake errors encountered in nqueen example
- PR #2018[3907] - For loop algorithms
- PR #2017[3908] - Non-recursive at_index implementation
- Issue #2016[3909] - Add index-based for-loops
- Issue #2015[3910] - Change default bind-mode to balanced
- PR #2014[3911] - Fixed dataflow if invoked action returns a future
- PR #2013[3912] - Fixing compilation issues with external example
- PR #2012[3913] - Added Sierpinski Triangle example
- Issue #2011[3914] - Compilation error while running sample hello_world_component code
- PR #2010[3915] - Segmented move implemented for hpx::vector
- Issue #2009[3916] - pkg-config order incorrect on 14.04 / GCC 4.8
- Issue #2008[3917] - Compilation error in dataflow of action returning a future
- PR #2007[3918] - Adding new performance counter exposing overall scheduler time
- PR #2006[3919] - Function includes
- PR #2005[3920] - Adding an example demonstrating how to initialize HPX from a global object
- PR #2004[3921] - Fixing 2000
- PR #2003[3922] - Adding generation parameter to gather to enable using it more than once
- PR #2002[3923] - Turn on position independent code to solve link problem with hpx_init
- Issue #2001[3924] - Gathering more than once segfaults
- Issue #2000[3925] - Undefined reference to hpx::assertion_failed
- Issue #1999[3926] - Seg fault in hpx::lcos::base_lco_with_value<*>::set_value_nonvirt() when running octo-tiger
- PR #1998[3927] - Detect unknown command line options

- Issue #55[4093] - Uniform syntax for enums should be implemented

2.10.15 *HPX* V0.9.11 (Nov 11, 2015)

Our main focus for this release was the design and development of a coherent set of higher-level APIs exposing various types of parallelism to the application programmer. We introduced the concepts of an `executor`, which can be used to customize the `where` and `when` of execution of tasks in the context of parallelizing codes. We extended all APIs related to managing parallel tasks to support executors which gives the user the choce of either using one of the predefined executor types or to provide its own, possibly application specific, executor. We paid very close attention to align all of these changes with the existing C++ Standards documents or with the ongoing proposals for standardization.

This release is the first after our change to a new development policy. We switched all development to be strictly performed on branches only, all direct commits to our main branch (`master`) are prohibited. Any change has to go through a peer review before it will be merged to `master`. As a result the overall stability of our code base has significantly increased, the development process itself has been simplified. This change manifests itself in a large number of pull-requests which have been merged (please see below for a full list of closed issues and pull-requests). All in all for this release, we closed almost 100 issues and merged over 290 pull-requests. There have been over 1600 commits to the master branch since the last release.

General changes

- We are moving into the direction of unifying managed and simple components. As such, the classes `hpx::components::component` and `hpx::components::component_base` have been added which currently just forward to the currently existing simple component facilities. The examples have been converted to only use those two classes.
- Added integration with the CircleCI[4094] hosted continuous integration service. This gives us constant and immediate feedback on the health of our master branch.
- The compiler configuration subsystem in the build system has been reimplemented. Instead of using Boost.Config we now use our own lightweight set of cmake scripts to determine the available language and library features supported by the used compiler.
- The API for creating instances of components has been consolidated. All component instances should be created using the `hpx::new_` only. It allows one to instantiate both, single component instances and multiple component instances. The placement of the created components can be controlled by special distribution policies. Please see the corresponding documentation outlining the use of `hpx::new_`.
- Introduced four new distribution policies which can be used with many API functions which traditionally expected to be used with a locality id. The new distribution policies are:
  - *`hpx::components::default_distribution_policy`* which tries to place multiple component instances as evenly as possible.

[4089] https://github.com/STEllAR-GROUP/hpx/issues/559
[4090] https://github.com/STEllAR-GROUP/hpx/issues/449
[4091] https://github.com/STEllAR-GROUP/hpx/issues/279
[4092] https://github.com/STEllAR-GROUP/hpx/issues/224
[4093] https://github.com/STEllAR-GROUP/hpx/issues/55
[4094] https://circleci.com/gh/STEllAR-GROUP/hpx

  - *hpx::components::colocating_distribution_policy* which will refer to the locality where a given component instance is currently placed.
  - *hpx::components::binpacking_distribution_policy* which will place multiple component instances as evenly as possible based on any performance counter.
  - *hpx::components::target_distribution_policy* which allows one to represent a given locality in the context of a distrwibution policy.
- The new distribution policies can now be also used with `hpx::async`. This change also deprecates `hpx::async_colocated(id, ...)` which now is replaced by a distribution policy: `hpx::async(hpx::colocated(id), ...)`.
- The `hpx::vector` and `hpx::unordered_map` data structures can now be used with the new distribution policies as well.
- The parallel facility `hpx::parallel::task_region` has been renamed to `hpx::parallel::task_block` based on the changes in the corresponding standardization proposal N4411[4095].
- Added extensions to the parallel facility `hpx::parallel::task_block` allowing to combine a task_block with an execution policy. This implies a minor breaking change as the `hpx::parallel::task_block` is now a template.
- Added new LCOs: `hpx::lcos::latch` and `hpx::lcos::local::latch` which semantically conform to the proposed `std::latch` (see N4399[4096]).
- Added performance counters exposing data related to data transferred by input/output (filesystem) operations (thanks to Maciej Brodowicz).
- Added performance counters allowing to track the number of action invocations (local and remote invocations).
- Added new command line options –hpx:print-counter-at and –hpx:reset-counters.
- The `hpx::vector` component has been renamed to `hpx::partitioned_vector` to make it explicit that the underlying memory is not contiguous.
- Introduced a completely new and uniform higher-level parallelism API which is based on executors. All existing parallelism APIs have been adapted to this. We have added a large number of different executor types, such as a numa-aware executor, a this-thread executor, etc.
- Added support for the MingW toolchain on Windows (thanks to Eric Lemanissier).
- HPX now includes support for APEX, (Autonomic Performance Environment for eXascale). APEX is an instrumentation and software adaptation library that provides an interface to TAU profiling / tracing as well as runtime adaptation of HPX applications through policy definitions. For more information and documentation, please see https://github.com/UO-OACISS/xpress-apex. To enable APEX at configuration time, specify `-DHPX_WITH_APEX=On`. To also include support for TAU profiling, specify `-DHPX_WITH_TAU=On` and specify the `-DTAU_ROOT`, `-DTAU_ARCH` and `-DTAU_OPTIONS` cmake parameters.
- We have implemented many more of the *Using parallel algorithms*. Please see Issue #1141[4097] for the list of all available parallel algorithms (thanks to Daniel Bourgeois and John Biddiscombe for contributing their work).

Breaking changes

- We are moving into the direction of unifying managed and simple components. In order to stop exposing the old facilities, all examples have been converted to use the new classes. The breaking change in this release is that performance counters are now a `hpx::components::component_base` instead of `hpx::components::managed_component_base`.
- We removed the support for stackless threads. It turned out that there was no performance benefit when using stackless threads. As such, we decided to clean up our codebase. This feature was not documented.
- The CMake project name has changed from 'hpx' to 'HPX' for consistency and compatibility with naming conventions and other CMake projects. Generated config files go into <prefix>/lib/cmake/HPX and not <prefix>/lib/cmake/hpx.
- The macro `HPX_REGISTER_MINIMAL_COMPONENT_FACTORY` has been deprecated. Please use *`HPX_REGISTER_COMPONENT`*. instead. The old macro will be removed in the next release.
- The obsolete distributing_factory and binpacking_factory components have been removed. The corresponding functionality is now provided by the `hpx::new_` API function in conjunction with the `hpx::default_layout` and `hpx::binpacking` distribution policies (*`hpx::components::default_distribution_policy`* and *`hpx::components::binpacking_distribution_policy`*)
- The API function `hpx::new_colocated` has been deprecated. Please use the consolidated API `hpx::new_` in conjunction with the new `hpx::colocated` distribution policy (*`hpx::components::colocating_distribution_policy`*) instead. The old API function will still be available for at least one release of *HPX* if the configuration variable `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` is enabled.
- The API function `hpx::async_colocated` has been deprecated. Please use the consolidated API `hpx::async` in conjunction with the new `hpx::colocated` distribution policy (*`hpx::components::colocating_distribution_policy`*) instead. The old API function will still be available for at least one release of *HPX* if the configuration variable `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` is enabled.
- The obsolete remote_object component has been removed.
- Replaced the use of Boost.Serialization with our own solution. While the new version is mostly compatible with Boost.Serialization, this change requires some minor code modifications in user code. For more information, please see the corresponding announcement[4098] on the hpx-users@stellar.cct.lsu.edu mailing list.
- The names used by cmake to influence various configuration options have been unified. The new naming scheme relies on all configuration constants to start with `HPX_WITH_...`, while the preprocessor constant which is used at build time starts with `HPX_HAVE_...`. For instance, the former cmake command line `-DHPX_MALLOC=...` now has to be specified a `-DHPX_WITH_MALLOC=...` and will cause the preprocessor constant `HPX_HAVE_MALLOC` to be defined. The actual name of the constant (i.e. `MALLOC`) has not changed. Please see the corresponding documentation for more details (*CMake variables used to configure HPX*).
- The `get_gid()` functions exposed by the component base classes `hpx::components::server::simple_component_base`, `hpx::components::server::managed_compone` and `hpx::components::server::fixed_component_base` have been replaced by two new functions: `get_unmanaged_id()` and `get_id()`. To enable the old function name for backwards compatibility, use the cmake configuration option `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On`.
- All functions which were named `get_gid()` but were returning `hpx::id_type` have been renamed to `get_id()`. To enable the old function names for backwards compatibility, use the cmake configuration option `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On`.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #1855[4099] - Completely removing external/endian
- PR #1854[4100] - Don't pollute CMAKE_CXX_FLAGS through find_package()
- PR #1853[4101] - Updating CMake configuration to get correct version of TAU library
- PR #1852[4102] - Fixing Performance Problems with MPI Parcelport
- PR #1851[4103] - Fixing hpx_add_link_flag() and hpx_remove_link_flag()
- PR #1850[4104] - Fixing 1836, adding parallel::sort
- PR #1849[4105] - Fixing configuration for use of more than 64 cores
- PR #1848[4106] - Change default APEX version for release
- PR #1847[4107] - Fix client_base::then on release
- PR #1846[4108] - Removing broken lcos::local::channel from release
- PR #1845[4109] - Adding example demonstrating a possible safe-object implementation to release
- PR #1844[4110] - Removing stubs from accumulator examples
- PR #1843[4111] - Don't pollute CMAKE_CXX_FLAGS through find_package()
- PR #1841[4112] - Fixing client_base<>::then
- PR #1840[4113] - Adding example demonstrating a possible safe-object implementation
- PR #1838[4114] - Update version rc1
- PR #1837[4115] - Removing broken lcos::local::channel
- PR #1835[4116] - Adding explicit move constructor and assignment operator to hpx::lcos::promise
- PR #1834[4117] - Making hpx::lcos::promise move-only
- PR #1833[4118] - Adding fedora docs
- Issue #1832[4119] - hpx::lcos::promise<> must be move-only

- PR #1704[4235] - vector deserialization is speeded up a little
- PR #1703[4236] - Fixing shared_mutes
- Issue #1702[4237] - Shared_mutex does not compile with no_mutex cond_var
- PR #1701[4238] - Add distribution_policy_executor
- PR #1700[4239] - Executor parameters
- PR #1699[4240] - Readers writer lock
- PR #1698[4241] - Remove leftovers
- PR #1697[4242] - Fixing held locks
- PR #1696[4243] - Modified Scan Partitioner for Algorithms
- PR #1695[4244] - This thread executors
- PR #1694[4245] - Fixed #1688: Add timer counters for tfunc_total and exec_total
- PR #1693[4246] - Fix #1691: is_executor template specification fails for inherited executors
- PR #1692[4247] - Fixed #1662: Possible exception source in coalescing_message_handler
- Issue #1691[4248] - is_executor template specification fails for inherited executors
- PR #1690[4249] - added macro for non-intrusive serialization of classes without a default c-tor
- PR #1689[4250] - Replace value_or_error with custom storage, unify future_data state
- Issue #1688[4251] - Add timer counters for tfunc_total and exec_total
- PR #1687[4252] - Fixed interval timer
- PR #1686[4253] - Fixing cmake warnings about not existing pseudo target dependencies
- PR #1685[4254] - Converting partitioners to use bulk async execute
- PR #1683[4255] - Adds a tool for inspect that checks for character limits
- PR #1682[4256] - Change project name to (uppercase) HPX
- PR #1681[4257] - Counter shortnames

- Issue #1629[4304] - Inspect trailing whitespace checker problem
- PR #1628[4305] - Removed meaningless const qualifiers. Minor icpc fix.
- PR #1627[4306] - Fixing the queue LCO and add example demonstrating its use
- PR #1626[4307] - Deprecating get_gid(), add get_id() and get_unmanaged_id()
- PR #1625[4308] - Allowing to specify whether to send credits along with message
- Issue #1624[4309] - Lifetime issue
- Issue #1623[4310] - hpx::wait_all() invoked with two vector<future<T>> fails
- PR #1622[4311] - Executor partitioners
- PR #1621[4312] - Clean up coroutines implementation
- Issue #1620[4313] - Revert #1535
- PR #1619[4314] - Fix result type calculation for hpx::make_continuation
- PR #1618[4315] - Fixing RDTSC on Xeon/Phi
- Issue #1617[4316] - hpx cmake not working when run as a subproject
- Issue #1616[4317] - cmake problem resulting in RDTSC not working correctly for Xeon Phi creates very strange results for duration counters
- Issue #1615[4318] - hpx::make_continuation requires input and output to be the same
- PR #1614[4319] - Fixed remove copy test
- Issue #1613[4320] - Dataflow causes stack overflow
- PR #1612[4321] - Modified foreach partitioner to use bulk execute
- PR #1611[4322] - Limit recursion-depth in dataflow to a configurable constant
- PR #1610[4323] - Increase timeout for CircleCI
- PR #1609[4324] - Refactoring thread manager, mainly extracting thread pool
- PR #1608[4325] - Fixed running multiple localities without localities parameter
- PR #1607[4326] - More algorithm fixes to adjacentfind

- PR #1555[4373] - Remove the necessity to specify archive flags on the receiving end
- PR #1554[4374] - Removing obsolete Boost.Serialization macros
- PR #1553[4375] - Properly fix HPX_DEFINE_*_ACTION macros
- PR #1552[4376] - Fixed algorithms relying on copy_if implementation
- PR #1551[4377] - Pxfs - Modifying FindOrangeFS.cmake based on OrangeFS 2.9.X
- Issue #1550[4378] - Passing plain identifier inside HPX_DEFINE_PLAIN_ACTION_1
- PR #1549[4379] - Fixing intel14/libstdc++4.4
- PR #1548[4380] - Moving raw_ptr to detail namespace
- PR #1547[4381] - Adding support for executors to future.then
- PR #1546[4382] - Executor traits result types
- PR #1545[4383] - Integrate executors with dataflow
- PR #1543[4384] - Fix potential zero-copy for primarynamespace::bulk_service_async et.al.
- PR #1542[4385] - Merging HPX0.9.10 into pxfs branch
- PR #1541[4386] - Removed stale cmake tests, unused since the great cmake refactoring
- PR #1540[4387] - Fix idle-rate on platforms without TSC
- PR #1539[4388] - Reporting situation if zero-copy-serialization was performed by a parcel generated from a plain apply/async
- PR #1538[4389] - Changed return type of bulk executors and added test
- Issue #1537[4390] - Incorrect cpuid config tests
- PR #1536[4391] - Changed return type of bulk executors and added test
- PR #1535[4392] - Make sure promise::get_gid() can be called more than once
- PR #1534[4393] - Fixed async_callback with bound callback
- PR #1533[4394] - Updated the link in the documentation to a publically- accessible URL
- PR #1532[4395] - Make sure sync primitives are not copyable nor movable

2.10.16 *HPX* V0.9.10 (Mar 24, 2015)

General changes

This is the 12th official release of *HPX*. It coincides with the 7th anniversary of the first commit to our source code repository. Since then, we have seen over 12300 commits amounting to more than 220000 lines of C++ code.

The major focus of this release was to improve the reliability of large scale runs. We believe to have achieved this goal as we now can reliably run *HPX* applications on up to ~24k cores. We have also shown that HPX can be used with success for symmetric runs (applications using both, host cores and Intel Xeon/Phi coprocessors). This is a huge step forward in terms of the usability of *HPX*. The main focus of this work involved isolating the causes of the segmentation faults at start up and shut down. Many of these issues were discovered to be the result of the suspension of threads which hold locks.

A very important improvement introduced with this release is the refactoring of the code representing our parcel-port implementation. Parcel- ports can now be implemented by 3rd parties as independent plugins which are dynamically loaded at runtime (static linking of parcel-ports is also supported). This refactoring also includes a massive improvement of the performance of our existing parcel-ports. We were able to significantly reduce the networking latencies

[4501] https://github.com/STEllAR-GROUP/hpx/issues/721
[4502] https://github.com/STEllAR-GROUP/hpx/issues/524

and to improve the available networking bandwidth. Please note that in this release we disabled the ibverbs and ipc parcel ports as those have not been ported to the new plugin system yet (see Issue #839[4503]).

Another corner stone of this release is our work towards a complete implementation of __cpp11_n4104__ (Working Draft, Technical Specification for C++ Extensions for Parallelism). This document defines a set of parallel algorithms to be added to the C++ standard library. We now have implemented about 75% of all specified parallel algorithms (see [link hpx.manual.parallel.parallel_algorithms Parallel Algorithms] for more details). We also implemented some extensions to __cpp11_n4104__ allowing to invoke all of the algorithms asynchronously.

This release adds a first implementation of `hpx::vector` which is a distributed data structure closely aligned to the functionality of `std::vector`. The difference is that `hpx::vector` stores the data in partitions where the partitions can be distributed over different localities. We started to work on allowing to use the parallel algorithms with `hpx::vector`. At this point we have implemented only a few of the parallel algorithms to support distributed data structures (like `hpx::vector`) for testing purposes (see Issue #1338[4504] for a documentation of our progress).

Breaking changes

With this release we put a lot of effort into changing the code base to be more compatible to C++11. These changes have caused the following issues for backward compatibility:

- Move to Variadics- All of the API now uses variadic templates. However, this change required to modify the argument sequence for some of the exiting API functions (*`hpx::async_continue`*, *`hpx::apply_continue`*, *`hpx::when_each`*, *`hpx::wait_each`*, synchronous invocation of actions).
- Changes to Macros- We also removed the macros `HPX_STD_FUNCTION` and `HPX_STD_TUPLE`. This shouldn't affect any user code as we replaced `HPX_STD_FUNCTION` with `hpx::util::function_nonser` which was the default expansion used for this macro. All *HPX* API functions which expect a `hpx::util::function_nonser` (or a `hpx::util::unique_function_nonser`) can now be transparently called with a compatible `std::function` instead. Similarly, `HPX_STD_TUPLE` was replaced by its default expansion as well: `hpx::util::tuple`.
- Changes to `hpx::unique_future`- `hpx::unique_future`, which was deprecated in the previous release for `hpx::future` is now completely removed from *HPX*. This completes the transition to a completely standards conforming implementation of `hpx::future`.
- Changes to Supported Compilers. Finally, in order to utilize more C++11 semantics, we have officially dropped support for GCC 4.4 and MSVC 2012. Please see our *Prerequisites* page for more details.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1402[4505] - Internal shared_future serialization copies
- Issue #1399[4506] - Build takes unusually long time...
- Issue #1398[4507] - Tests using the scan partitioner are broken on at least gcc 4.7 and intel compiler
- Issue #1397[4508] - Completely remove hpx::unique_future
- Issue #1396[4509] - Parallel scan algorithms with different initial values

[4508] https://github.com/STEllAR-GROUP/hpx/issues/1397
[4509] https://github.com/STEllAR-GROUP/hpx/issues/1396

- Issue #1395[4510] - Race Condition - 1d_stencil_8 - SuperMIC
- Issue #1394[4511] - "suspending thread while at least one lock is being held" - 1d_stencil_8 - SuperMIC
- Issue #1393[4512] - SEGFAULT in 1d_stencil_8 on SuperMIC
- Issue #1392[4513] - Fixing #1168
- Issue #1391[4514] - Parallel Algorithms for scan partitioner for small number of elements
- Issue #1387[4515] - Failure with more than 4 localities
- Issue #1386[4516] - Dispatching unhandled exceptions to outer user code
- Issue #1385[4517] - Adding Copy algorithms, fixing `parallel::copy_if`
- Issue #1384[4518] - Fixing 1325
- Issue #1383[4519] - Fixed #504: Refactor Dataflow LCO to work with futures, this removes the dataflow component as it is obsolete
- Issue #1382[4520] - `is_sorted`, `is_sorted_until` and `is_partitioned` algorithms
- Issue #1381[4521] - fix for CMake versions prior to 3.1
- Issue #1380[4522] - resolved warning in CMake 3.1 and newer
- Issue #1379[4523] - Compilation error with papi
- Issue #1378[4524] - Towards safer migration
- Issue #1377[4525] - HPXConfig.cmake should include `TCMALLOC_LIBRARY` and `TCMALLOC_INCLUDE_DIR`
- Issue #1376[4526] - Warning on uninitialized member
- Issue #1375[4527] - Fixing 1163
- Issue #1374[4528] - Fixing the MSVC 12 release builder
- Issue #1373[4529] - Modifying parallel search algorithm for zero length searches
- Issue #1372[4530] - Modifying parallel search algorithm for zero length searches
- Issue #1371[4531] - Avoid holding a lock during agas::incref while doing a credit split
- Issue #1370[4532] - `--hpx:bind` throws unexpected error

- Issue #1346[4556] - Segmented copy
- Issue #1345[4557] - Attempting to fix hangs during shutdown
- Issue #1344[4558] - Std config removal
- Issue #1343[4559] - Removing various distribution policies for hpx::vector
- Issue #1342[4560] - Inclusive scan
- Issue #1341[4561] - Exclusive scan
- Issue #1340[4562] - Adding `parallel::count` for distributed data structures, adding tests
- Issue #1339[4563] - Update argument order for transform_reduce
- Issue #1337[4564] - Fix dataflow to handle properly ranges of futures
- Issue #1336[4565] - dataflow needs to hold onto futures passed to it
- Issue #1335[4566] - Fails to compile with msvc14
- Issue #1334[4567] - Examples build problem
- Issue #1333[4568] - Distributed transform reduce
- Issue #1332[4569] - Variadic templates support for actions
- Issue #1331[4570] - Some ambiguous calls of map::erase have been prevented by adding additional check in locality constructor.
- Issue #1330[4571] - Defining Plain Actions does not work as described in the documentation
- Issue #1329[4572] - Distributed vector cleanup
- Issue #1328[4573] - Sync docs and comments with code in hello_world example
- Issue #1327[4574] - Typos in docs
- Issue #1326[4575] - Documentation and code diverged in Fibonacci tutorial
- Issue #1325[4576] - Exceptions thrown during parcel handling are not handled correctly
- Issue #1324[4577] - fixed bandwidth calculation
- Issue #1323[4578] - mmap() failed to allocate thread stack due to insufficient resources

- Issue #1294[4601] - HDF5 build error
- Issue #1275[4602] - The parcelport implementation is non-optimal
- Issue #1267[4603] - Added classes and unit tests for local_file, orangefs_file and pxfs_file
- Issue #1264[4604] - Error "assertion '!m_fun' failed" randomly occurs when using TCP
- Issue #1254[4605] - thread binding seems to not work properly
- Issue #1220[4606] - parallel::copy_if is broken
- Issue #1217[4607] - Find a better way of fixing the issue patched by #1216
- Issue #1168[4608] - Starting HPX on Cray machines using aprun isn't working correctly
- Issue #1085[4609] - Replace startup and shutdown barriers with broadcasts
- Issue #981[4610] - With SLURM, –hpx:threads=8 should not be necessary
- Issue #857[4611] - hpx::naming::locality leaks parcelport specific information into the public interface
- Issue #850[4612] - "flush" not documented
- Issue #763[4613] - Create buildbot instance that uses std::bind as HPX_STD_BIND
- Issue #680[4614] - Convert parcel ports into a plugin system
- Issue #582[4615] - Make exception thrown from HPX threads available from `hpx::init`
- Issue #504[4616] - Refactor Dataflow LCO to work with futures
- Issue #196[4617] - Don't store copies of the locality network metadata in the gva table

2.10.17 *HPX* V0.9.9 (Oct 31, 2014, codename Spooky)

General changes

We have had over 1500 commits since the last release and we have closed over 200 tickets (bugs, feature requests, pull requests, etc.). These are by far the largest numbers of commits and resolved issues for any of the *HPX* releases so far. We are especially happy about the large number of people who contributed for the first time to *HPX*.

- We completed the transition from the older (non-conforming) implementation of `hpx::future` to the new and fully conforming version by removing the old code and by renaming the type `hpx::unique_future` to `hpx::future`. In order to maintain backwards compatibility with existing code which uses the type `hpx::unique_future` we support the configuration variable `HPX_UNIQUE_FUTURE_ALIAS`. If this variable is set to `ON` while running cmake it will additionally define a template alias for this type.

[4617] https://github.com/STEllAR-GROUP/hpx/issues/196

- We rewrote and significantly changed our build system. Please have a look at the new (now generated) documentation here: hpx_build_system. Please revisit your build scripts to adapt to the changes. The most notable changes are:
  - `HPX_NO_INSTALL` is no longer necessary.
  - For external builds, you need to set `HPX_DIR` instead of `HPX_ROOT` as described here: *Using HPX with CMake-based projects*.
  - IDEs that support multiple configurations (Visual Studio and XCode) can now be used as intended. that means no build dir.
  - Building HPX statically (without dynamic libraries) is now supported (`-DHPX_STATIC_LINKING=On`).
  - Please note that many variables used to configure the build process have been renamed to unify the naming conventions (see the section *CMake variables used to configure HPX* for more information).
  - This also fixes a long list of issues, for more information see Issue #1204[4618].
- We started to implement various proposals to the C++ Standardization committee related to parallelism and concurrency, most notably N4409[4619] (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411[4620] (Task Region Rev. 3), and N4313[4621] (Working Draft, Technical Specification for C++ Extensions for Concurrency).
- We completely remodeled our automatic build system to run builds and unit tests on various systems and compilers. This allows us to find most bugs right as they were introduced and helps to maintain a high level of quality and compatibility. The newest build logs can be found at *HPX* Buildbot Website[4622].

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1296[4623] - Rename make_error_future to make_exceptional_future, adjust to N4123
- Issue #1295[4624] - building issue
- Issue #1293[4625] - Transpose example
- Issue #1292[4626] - Wrong abs() function used in example
- Issue #1291[4627] - non-synchronized shift operators have been removed
- Issue #1290[4628] - RDTSCP is defined as true for Xeon Phi build
- Issue #1289[4629] - Fixing 1288
- Issue #1288[4630] - Add new performance counters
- Issue #1287[4631] - Hierarchy scheduler broken performance counters

- Issue #1259[4655] - Avoid double-linking Boost on Windows
- Issue #1257[4656] - Adding additional parameter to create_thread
- Issue #1256[4657] - added buildbot changes to release notes
- Issue #1255[4658] - Cannot build MiniGhost
- Issue #1253[4659] - hpx::thread defects
- Issue #1252[4660] - HPX_PREFIX is too fragile
- Issue #1250[4661] - switch_to_fiber_emulation does not work properly
- Issue #1249[4662] - Documentation is generated under Release folder
- Issue #1248[4663] - Fix usage of hpx_generic_coroutine_context and get tests passing on powerpc
- Issue #1247[4664] - Dynamic linking error
- Issue #1246[4665] - Make cpuid.cpp C++11 compliant
- Issue #1245[4666] - HPX fails on startup (setting thread affinity mask)
- Issue #1244[4667] - HPX_WITH_RDTSC configure test fails, but should succeed
- Issue #1243[4668] - CTest dashboard info for CSCS CDash drop location
- Issue #1242[4669] - Mac fixes
- Issue #1241[4670] - Failure in Distributed with Boost 1.56
- Issue #1240[4671] - fix a race condition in examples.diskperf
- Issue #1239[4672] - fix wait_each in examples.diskperf
- Issue #1238[4673] - Fixed #1237: hpx::util::portable_binary_iarchive failed
- Issue #1237[4674] - hpx::util::portable_binary_iarchive faileds
- Issue #1235[4675] - Fixing clang warnings and errors
- Issue #1234[4676] - TCP runs fail: Transport endpoint is not connected
- Issue #1233[4677] - Making sure the correct number of threads is registered with AGAS

- Issue #1232[4678] - Fixing race in wait_xxx
- Issue #1231[4679] - Parallel minmax
- Issue #1230[4680] - Distributed run of 1d_stencil_8 uses less threads than spec. & sometimes gives errors
- Issue #1229[4681] - Unstable number of threads
- Issue #1228[4682] - HPX link error (cmake / MPI)
- Issue #1226[4683] - Warning about struct/class thread_counters
- Issue #1225[4684] - Adding parallel::replace etc
- Issue #1224[4685] - Extending dataflow to pass through non-future arguments
- Issue #1223[4686] - Remaining find algorithms implemented, N4071
- Issue #1222[4687] - Merging all the changes
- Issue #1221[4688] - No error output when using mpirun with hpx
- Issue #1219[4689] - Adding new AGAS cache performance counters
- Issue #1216[4690] - Fixing using futures (clients) as arguments to actions
- Issue #1215[4691] - Error compiling simple component
- Issue #1214[4692] - Stencil docs
- Issue #1213[4693] - Using more than a few dozen MPI processes on SuperMike results in a seg fault before getting to hpx_main
- Issue #1212[4694] - Parallel rotate
- Issue #1211[4695] - Direct actions cause the future's shared_state to be leaked
- Issue #1210[4696] - Refactored local::promise to be standard conformant
- Issue #1209[4697] - Improve command line handling
- Issue #1208[4698] - Adding parallel::reverse and parallel::reverse_copy
- Issue #1207[4699] - Add copy_backward and move_backward
- Issue #1206[4700] - N4071 additional algorithms implemented

- Issue #1204[4701] - Cmake simplification and various other minor changes
- Issue #1203[4702] - Implementing new launch policy for (local) async: `hpx::launch::fork`.
- Issue #1202[4703] - Failed assertion in connection_cache.hpp
- Issue #1201[4704] - pkg-config doesn't add mpi link directories
- Issue #1200[4705] - Error when querying time performance counters
- Issue #1199[4706] - library path is now configurable (again)
- Issue #1198[4707] - Error when querying performance counters
- Issue #1197[4708] - tests fail with intel compiler
- Issue #1196[4709] - Silence several warnings
- Issue #1195[4710] - Rephrase initializers to work with VC++ 2012
- Issue #1194[4711] - Simplify parallel algorithms
- Issue #1193[4712] - Adding `parallel::equal`
- Issue #1192[4713] - HPX(out_of_memory) on including <hpx/hpx.hpp>
- Issue #1191[4714] - Fixing #1189
- Issue #1190[4715] - Chrono cleanup
- Issue #1189[4716] - Deadlock .. somewhere? (probably serialization)
- Issue #1188[4717] - Removed `future::get_status()`
- Issue #1186[4718] - Fixed FindOpenCL to find current AMD APP SDK
- Issue #1184[4719] - Tweaking future unwrapping
- Issue #1183[4720] - Extended `parallel::reduce`
- Issue #1182[4721] - `future::unwrap` hangs for `launch::deferred`
- Issue #1181[4722] - Adding `all_of`, `any_of`, and `none_of` and corresponding documentation
- Issue #1180[4723] - `hpx::cout` defect

- Issue #1179[4724] - `hpx::async` does not work for member function pointers when called on types with self-defined unary `operator*`
- Issue #1178[4725] - Implemented variadic `hpx::util::zip_iterator`
- Issue #1177[4726] - MPI parcelport defect
- Issue #1176[4727] - `HPX_DEFINE_COMPONENT_CONST_ACTION_TPL` does not have a 2-argument version
- Issue #1175[4728] - Create util::zip_iterator working with util::tuple<>
- Issue #1174[4729] - Error Building HPX on linux, root_certificate_authority.cpp
- Issue #1173[4730] - hpx::cout output lost
- Issue #1172[4731] - HPX build error with Clang 3.4.2
- Issue #1171[4732] - `CMAKE_INSTALL_PREFIX` ignored
- Issue #1170[4733] - Close hpx_benchmarks repository on Github
- Issue #1169[4734] - Buildbot emails have syntax error in url
- Issue #1167[4735] - Merge partial implementation of standards proposal N3960
- Issue #1166[4736] - Fixed several compiler warnings
- Issue #1165[4737] - cmake warns: "tests.regressions.actions" does not exist
- Issue #1164[4738] - Want my own serialization of hpx::future
- Issue #1162[4739] - Segfault in hello_world example
- Issue #1161[4740] - Use `HPX_ASSERT` to aid the compiler
- Issue #1160[4741] - Do not put -DNDEBUG into hpx_application.pc
- Issue #1159[4742] - Support Clang 3.4.2
- Issue #1158[4743] - Fixed #1157: Rename when_n/wait_n, add when_xxx_n/wait_xxx_n
- Issue #1157[4744] - Rename when_n/wait_n, add when_xxx_n/wait_xxx_n
- Issue #1156[4745] - Force inlining fails
- Issue #1155[4746] - changed header of printout to be compatible with python csv module

- Issue #1154[4747] - Fixing iostreams
- Issue #1153[4748] - Standard manipulators (like std::endl) do not work with hpx::ostream
- Issue #1152[4749] - Functions revamp
- Issue #1151[4750] - Suppressing cmake 3.0 policy warning for CMP0026
- Issue #1150[4751] - Client Serialization error
- Issue #1149[4752] - Segfault on Stampede
- Issue #1148[4753] - Refactoring mini-ghost
- Issue #1147[4754] - N3960 copy_if and copy_n implemented and tested
- Issue #1146[4755] - Stencil print
- Issue #1145[4756] - N3960 hpx::parallel::copy implemented and tested
- Issue #1144[4757] - OpenMP examples 1d_stencil do not build
- Issue #1143[4758] - 1d_stencil OpenMP examples do not build
- Issue #1142[4759] - Cannot build HPX with gcc 4.6 on OS X
- Issue #1140[4760] - Fix OpenMP lookup, enable usage of config tests in external CMake projects.
- Issue #1139[4761] - hpx/hpx/config/compiler_specific.hpp
- Issue #1138[4762] - clean up pkg-config files
- Issue #1137[4763] - Improvements to create binary packages
- Issue #1136[4764] - HPX_GCC_VERSION not defined on all compilers
- Issue #1135[4765] - Avoiding collision between winsock2.h and windows.h
- Issue #1134[4766] - Making sure, that hpx::finalize can be called from any locality
- Issue #1133[4767] - 1d stencil examples
- Issue #1131[4768] - Refactor unique_function implementation
- Issue #1130[4769] - Unique function

- Issue #1129[4770] - Some fixes to the Build system on OS X
- Issue #1128[4771] - Action future args
- Issue #1127[4772] - Executor causes segmentation fault
- Issue #1124[4773] - Adding new API functions: `register_id_with_basename`, `unregister_id_with_basename`, `find_ids_from_basename`; adding test
- Issue #1123[4774] - Reduce nesting of try-catch construct in `encode_parcels`?
- Issue #1122[4775] - Client base fixes
- Issue #1121[4776] - Update `hpxrun.py.in`
- Issue #1120[4777] - HTTS2 tests compile errors on v110 (VS2012)
- Issue #1119[4778] - Remove references to boost::atomic in accumulator example
- Issue #1118[4779] - Only build test thread_pool_executor_1114_test if `HPX_SCHEDULER` is set
- Issue #1117[4780] - local_queue_executor linker error on vc110
- Issue #1116[4781] - Disabled performance counter should give runtime errors, not invalid data
- Issue #1115[4782] - Compile error with Intel C++ 13.1
- Issue #1114[4783] - Default constructed executor is not usable
- Issue #1113[4784] - Fast compilation of logging causes ABI incompatibilities between different `NDEBUG` values
- Issue #1112[4785] - Using thread_pool_executors causes segfault
- Issue #1111[4786] - `hpx::threads::get_thread_data` always returns zero
- Issue #1110[4787] - Remove unnecessary null pointer checks
- Issue #1109[4788] - More tests adjustments
- Issue #1108[4789] - Clarify build rules for "libboost_atomic-mt.so"?
- Issue #1107[4790] - Remove unnecessary null pointer checks
- Issue #1106[4791] - network_storage benchmark improvements, adding legends to plots and tidying layout
- Issue #1105[4792] - Add more plot outputs and improve instructions doc

- Issue #1104[4793] - Complete quoting for parameters of some CMake commands
- Issue #1103[4794] - Work on test/scripts
- Issue #1102[4795] - Changed minimum requirement of window install to 2012
- Issue #1101[4796] - Changed minimum requirement of window install to 2012
- Issue #1100[4797] - Changed readme to no longer specify using MSVC 2010 compiler
- Issue #1099[4798] - Error returning futures from component actions
- Issue #1098[4799] - Improve storage test
- Issue #1097[4800] - data_actions quickstart example calls missing function decorate_action of data_get_action
- Issue #1096[4801] - MPI parcelport broken with new zero copy optimization
- Issue #1095[4802] - Warning C4005: _WIN32_WINNT: Macro redefinition
- Issue #1094[4803] - Syntax error for -DHPX_UNIQUE_FUTURE_ALIAS in master
- Issue #1093[4804] - Syntax error for -DHPX_UNIQUE_FUTURE_ALIAS
- Issue #1092[4805] - Rename unique_future<> back to future<>
- Issue #1091[4806] - Inconsistent error message
- Issue #1090[4807] - On windows 8.1 the examples crashed if using more than one os thread
- Issue #1089[4808] - Components should be allowed to have their own executor
- Issue #1088[4809] - Add possibility to select a network interface for the ibverbs parcelport
- Issue #1087[4810] - ibverbs and ipc parcelport uses zero copy optimization
- Issue #1083[4811] - Make shell examples copyable in docs
- Issue #1082[4812] - Implement proper termination detection during shutdown
- Issue #1081[4813] - Implement thread_specific_ptr for hpx::threads
- Issue #1072[4814] - make install not working properly
- Issue #1070[4815] - Complete quoting for parameters of some CMake commands

- Issue #456[4839] - hpx_run_tests.py should log output from tests that timeout
- Issue #454[4840] - Investigate threadmanager performance
- Issue #345[4841] - Add more versatile environmental/cmake variable support to hpx_find_* CMake macros
- Issue #209[4842] - Support multiple configurations in generated build files
- Issue #190[4843] - hpx::cout should be a std::ostream
- Issue #189[4844] - iostreams component should use startup/shutdown functions
- Issue #183[4845] - Use Boost.ICL for correctness in AGAS
- Issue #44[4846] - Implement real futures

2.10.18 *HPX* V0.9.8 (Mar 24, 2014)

We have had over 800 commits since the last release and we have closed over 65 tickets (bugs, feature requests, etc.).

With the changes below, *HPX* is once again leading the charge of a whole new era of computation. By intrinsically breaking down and synchronizing the work to be done, *HPX* insures that application developers will no longer have to fret about where a segment of code executes. That allows coders to focus their time and energy to understanding the data dependencies of their algorithms and thereby the core obstacles to an efficient code. Here are some of the advantages of using *HPX*:

- *HPX* is solidly rooted in a sophisticated theoretical execution model – ParalleX
- *HPX* exposes an API fully conforming to the C++11 and the draft C++14 standards, extended and applied to distributed computing. Everything programmers know about the concurrency primitives of the standard C++ library is still valid in the context of *HPX*.
- It provides a competitive, high performance implementation of modern, future-proof ideas which gives an smooth migration path from today's mainstream techniques
- There is no need for the programmer to worry about lower level parallelization paradigms like threads or message passing; no need to understand pthreads, MPI, OpenMP, or Windows threads, etc.
- There is no need to think about different types of parallelism such as tasks, pipelines, or fork-join, task or data parallelism.
- The same source of your program compiles and runs on Linux, BlueGene/Q, Mac OS X, Windows, and Android.
- The same code runs on shared memory multi-core systems and supercomputers, on handheld devices and Intel® Xeon Phi™ accelerators, or a heterogeneous mix of those.

[4846] https://github.com/STEllAR-GROUP/hpx/issues/44

General changes

- A major API breaking change for this release was introduced by implementing `hpx::future` and `hpx::shared_future` fully in conformance with the C++11 Standard[4847]. While `hpx::shared_future` is new and will not create any compatibility problems, we revised the interface and implementation of the existing `hpx::future`. For more details please see the mailing list archive[4848]. To avoid any incompatibilities for existing code we named the type which implements the `std::future` interface as `hpx::unique_future`. For the next release this will be renamed to `hpx::future`, making it full conforming to C++11 Standard[4849].
- A large part of the code base of *HPX* has been refactored and partially re-implemented. The main changes were related to
  - The threading subsystem: these changes significantly reduce the amount of overheads caused by the schedulers, improve the modularity of the code base, and extend the variety of available scheduling algorithms.
  - The parcel subsystem: these changes improve the performance of the *HPX* networking layer, modularize the structure of the parcelports, and simplify the creation of new parcelports for other underlying networking libraries.
  - The API subsystem: these changes improved the conformance of the API to C++11 Standard, extend and unify the available API functionality, and decrease the overheads created by various elements of the API.
  - The robustness of the component loading subsystem has been improved significantly, allowing to more portably and more reliably register the components needed by an application as startup. This additionally speeds up general application initialization.
- We added new API functionality like `hpx::migrate` and `hpx::copy_component` which are the basic building blocks necessary for implementing higher level abstractions for system-wide load balancing, runtime-adaptive resource management, and object-oriented checkpointing and state-management.
- We removed the use of C++11 move emulation (using Boost.Move), replacing it with C++11 rvalue references. This is the first step towards using more and more native C++11 facilities which we plan to introduce in the future.
- We improved the reference counting scheme used by *HPX* which helps managing distributed objects and memory. This improves the overall stability of *HPX* and further simplifies writing real world applications.
- The minimal Boost version required to use *HPX* is now V1.49.0.
- This release coincides with the first release of HPXPI (V0.1.0), the first implementation of the XPI specification[4850].

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1086[4851] - Expose internal boost::shared_array to allow user management of array lifetime
- Issue #1083[4852] - Make shell examples copyable in docs
- Issue #1080[4853] - /threads{locality#*/total}/count/cumulative broken

[4853] https://github.com/STEllAR-GROUP/hpx/issues/1080

- Issue #1079[4854] - Build problems on OS X
- Issue #1078[4855] - Improve robustness of component loading
- Issue #1077[4856] - Fix a missing enum definition for 'take' mode
- Issue #1076[4857] - Merge Jb master
- Issue #1075[4858] - Unknown CMake command "add_hpx_pseudo_target"
- Issue #1074[4859] - Implement `apply_continue_callback` and `apply_colocated_callback`
- Issue #1073[4860] - The new `apply_colocated` and `async_colocated` functions lead to automatic registered functions
- Issue #1071[4861] - Remove deferred_packaged_task
- Issue #1069[4862] - serialize_buffer with allocator fails at destruction
- Issue #1068[4863] - Coroutine include and forward declarations missing
- Issue #1067[4864] - Add allocator support to util::serialize_buffer
- Issue #1066[4865] - Allow for MPI_Init being called before HPX launches
- Issue #1065[4866] - AGAS cache isn't used/populated on worker localities
- Issue #1064[4867] - Reorder includes to ensure ws2 includes early
- Issue #1063[4868] - Add `hpx::runtime::suspend` and `hpx::runtime::resume`
- Issue #1062[4869] - Fix `async_continue` to properly handle return types
- Issue #1061[4870] - Implement `async_colocated` and `apply_colocated`
- Issue #1060[4871] - Implement minimal component migration
- Issue #1058[4872] - Remove `HPX_UTIL_TUPLE` from code base
- Issue #1057[4873] - Add performance counters for threading subsystem
- Issue #1055[4874] - Thread allocation uses two memory pools
- Issue #1053[4875] - Work stealing flawed
- Issue #1052[4876] - Fix a number of warnings

- Issue #1049[4877] - Fixes for TLS on OSX and more reliable test running
- Issue #1048[4878] - Fixing after 588 hang
- Issue #1047[4879] - Use port '0' for networking when using one locality
- Issue #1046[4880] - `composable_guard` test is broken when having more than one thread
- Issue #1045[4881] - Security missing headers
- Issue #1044[4882] - Native TLS on FreeBSD via __thread
- Issue #1043[4883] - `async` et.al. compute the wrong result type
- Issue #1042[4884] - `async` et.al. implicitly unwrap reference_wrappers
- Issue #1041[4885] - Remove redundant costly Kleene stars from regex searches
- Issue #1040[4886] - CMake script regex match patterns has unnecessary kleenes
- Issue #1039[4887] - Remove use of Boost.Move and replace with std::move and real rvalue refs
- Issue #1038[4888] - Bump minimal required Boost to 1.49.0
- Issue #1037[4889] - Implicit unwrapping of futures in async broken
- Issue #1036[4890] - Scheduler hangs when user code attempts to "block" OS-threads
- Issue #1035[4891] - Idle-rate counter always reports 100% idle rate
- Issue #1034[4892] - Symbolic name registration causes application hangs
- Issue #1033[4893] - Application options read in from an options file generate an error message
- Issue #1032[4894] - `hpx::id_type` local reference counting is wrong
- Issue #1031[4895] - Negative entry in reference count table
- Issue #1030[4896] - Implement condition_variable
- Issue #1029[4897] - Deadlock in thread scheduling subsystem
- Issue #1028[4898] - HPX-thread cumulative count performance counters report incorrect value
- Issue #1027[4899] - Expose `hpx::thread_interrupted` error code as a separate exception type

- Issue #1026[4900] - Exceptions thrown in asynchronous calls can be lost if the value of the future is never queried
- Issue #1025[4901] - `future::wait_for/wait_until` do not remove callback
- Issue #1024[4902] - Remove dependence to boost assert and create hpx assert
- Issue #1023[4903] - Segfaults with tcmalloc
- Issue #1022[4904] - prerequisites link in readme is broken
- Issue #1020[4905] - HPX Deadlock on external synchronization
- Issue #1019[4906] - Convert using `BOOST_ASSERT` to `HPX_ASSERT`
- Issue #1018[4907] - compiling bug with gcc 4.8.1
- Issue #1017[4908] - Possible crash in io_pool executor
- Issue #1016[4909] - Crash at startup
- Issue #1014[4910] - Implement Increment/Decrement Merging
- Issue #1013[4911] - Add more logging channels to enable greater control over logging granularity
- Issue #1012[4912] - `--hpx:debug-hpx-log` and `--hpx:debug-agas-log` lead to non-thread safe writes
- Issue #1011[4913] - After installation, running applications from the build/staging directory no longer works
- Issue #1010[4914] - Mergeable decrement requests are not being merged
- Issue #1009[4915] - `--hpx:list-symbolic-names` crashes
- Issue #1007[4916] - Components are not properly destroyed
- Issue #1006[4917] - Segfault/hang in set_data
- Issue #1003[4918] - Performance counter naming issue
- Issue #982[4919] - Race condition during startup
- Issue #912[4920] - OS X: component type not found in map
- Issue #663[4921] - Create a buildbot slave based on Clang 3.2/OSX
- Issue #636[4922] - Expose `this_locality::apply<act>(p1, p2);` for local execution

- Issue #197[4923] - Add `--console=address` option for PBS runs
- Issue #175[4924] - Asynchronous AGAS API

2.10.19 *HPX* V0.9.7 (Nov 13, 2013)

We have had over 1000 commits since the last release and we have closed over 180 tickets (bugs, feature requests, etc.).

General changes

- Ported HPX to BlueGene/Q
- Improved HPX support for Xeon/Phi accelerators
- Reimplemented `hpx::bind`, `hpx::tuple`, and `hpx::function` for better performance and better compliance with the C++11 Standard. Added `hpx::mem_fn`.
- Reworked `hpx::when_all` and `hpx::when_any` for better compliance with the ongoing C++ standardization effort, added heterogeneous version for those functions. Added `hpx::when_any_swapped`.
- Added `hpx::copy` as a precursor for a migrate functionality
- Added `hpx::get_ptr` allowing to directly access the memory underlying a given component
- Added the `hpx::lcos::broadcast`, `hpx::lcos::reduce`, and `hpx::lcos::fold` collective operations
- Added `hpx::get_locality_name` allowing to retrieve the name of any of the localities for the application.
- Added support for more flexible thread affinity control from the HPX command line, such as new modes for `--hpx:bind` (`balanced`, `scattered`, `compact`), improved default settings when running multiple localities on the same node.
- Added experimental executors for simpler thread pooling and scheduling. This API may change in the future as it will stay aligned with the ongoing C++ standardization efforts.
- Massively improved the performance of the HPX serialization code. Added partial support for zero copy serialization of array and bitwise-copyable types.
- General performance improvements of the code related to threads and futures.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1005[4925] - Allow one to disable array optimizations and zero copy optimizations for each parcelport
- Issue #1004[4926] - Generate new HPX logo image for the docs
- Issue #1002[4927] - If MPI parcelport is not available, running HPX under mpirun should fail
- Issue #1001[4928] - Zero copy serialization raises assert

[4924] https://github.com/STEllAR-GROUP/hpx/issues/175
[4925] https://github.com/STEllAR-GROUP/hpx/issues/1005
[4926] https://github.com/STEllAR-GROUP/hpx/issues/1004
[4927] https://github.com/STEllAR-GROUP/hpx/issues/1002
[4928] https://github.com/STEllAR-GROUP/hpx/issues/1001

- Issue #1000[4929] - Can't connect to a HPX application running with the MPI parcelport from a non MPI parcelport locality
- Issue #999[4930] - Optimize `hpx::when_n`
- Issue #998[4931] - Fixed const-correctness
- Issue #997[4932] - Making serialize_buffer::data() type save
- Issue #996[4933] - Memory leak in hpx::lcos::promise
- Issue #995[4934] - Race while registering pre-shutdown functions
- Issue #994[4935] - thread_rescheduling regression test does not compile
- Issue #992[4936] - Correct comments and messages
- Issue #991[4937] - setcap cap_sys_rawio=ep for power profiling causes an HPX application to abort
- Issue #989[4938] - Jacobi hangs during execution
- Issue #988[4939] - multiple_init test is failing
- Issue #986[4940] - Can't call a function called "init" from "main" when using `<hpx/hpx_main.hpp>`
- Issue #984[4941] - Reference counting tests are failing
- Issue #983[4942] - thread_suspension_executor test fails
- Issue #980[4943] - Terminating HPX threads don't leave stack in virgin state
- Issue #979[4944] - Static scheduler not in documents
- Issue #978[4945] - Preprocessing limits are broken
- Issue #977[4946] - Make tests.regressions.lcos.future_hang_on_get shorter
- Issue #976[4947] - Wrong library order in pkgconfig
- Issue #975[4948] - Please reopen #963
- Issue #974[4949] - Option pu-offset ignored in fixing_588 branch
- Issue #972[4950] - Cannot use MKL with HPX
- Issue #969[4951] - Non-existent INI files requested on the command line via `--hpx:config` do not cause warn-

ings or errors.

- Issue #968[4952] - Cannot build examples in fixing_588 branch
- Issue #967[4953] - Command line description of `--hpx:queuing` seems wrong
- Issue #966[4954] - `--hpx:print-bind` physical core numbers are wrong
- Issue #965[4955] - Deadlock when building in Release mode
- Issue #963[4956] - Not all worker threads are working
- Issue #962[4957] - Problem with SLURM integration
- Issue #961[4958] - `--hpx:print-bind` outputs incorrect information
- Issue #960[4959] - Fix cut and paste error in documentation of get_thread_priority
- Issue #959[4960] - Change link to boost.atomic in documentation to point to boost.org
- Issue #958[4961] - Undefined reference to intrusive_ptr_release
- Issue #957[4962] - Make tuple standard compliant
- Issue #956[4963] - Segfault with a3382fb
- Issue #955[4964] - `--hpx:nodes` and `--hpx:nodefiles` do not work with foreign nodes
- Issue #954[4965] - Make order of arguments for hpx::async and hpx::broadcast consistent
- Issue #953[4966] - Cannot use MKL with HPX
- Issue #952[4967] - `register_[pre_]shutdown_function` never throw
- Issue #951[4968] - Assert when number of threads is greater than hardware concurrency
- Issue #948[4969] - `HPX_HAVE_GENERIC_CONTEXT_COROUTINES` conflicts with `HPX_HAVE_FIBER_BASED_COROUTINES`
- Issue #947[4970] - Need MPI_THREAD_MULTIPLE for backward compatibility
- Issue #946[4971] - HPX does not call `MPI_Finalize`
- Issue #945[4972] - Segfault with `hpx::lcos::broadcast`
- Issue #944[4973] - OS X: assertion `pu_offset_ < hardware_concurrency` failed

- Issue #943[4974] - #include <hpx/hpx_main.hpp> does not work
- Issue #942[4975] - Make the BG/Q work with -O3
- Issue #940[4976] - Use separator when concatenating locality name
- Issue #939[4977] - Refactor MPI parcelport to use `MPI_Wait` instead of multiple `MPI_Test` calls
- Issue #938[4978] - Want to officially access `client_base::gid_`
- Issue #937[4979] - `client_base::gid_` should be private``
- Issue #936[4980] - Want doxygen-like source code index
- Issue #935[4981] - Build error with gcc 4.6 and Boost 1.54.0 on hpx trunk and 0.9.6
- Issue #933[4982] - Cannot build HPX with Boost 1.54.0
- Issue #932[4983] - Components are destructed too early
- Issue #931[4984] - Make HPX work on BG/Q
- Issue #930[4985] - make git-docs is broken
- Issue #929[4986] - Generating index in docs broken
- Issue #928[4987] - Optimize `hpx::util::static_` for C++11 compilers supporting magic statics
- Issue #924[4988] - Make kill_process_tree (in process.py) more robust on Mac OSX
- Issue #923[4989] - Correct BLAS and RNPL cmake tests
- Issue #922[4990] - Cannot link against BLAS
- Issue #921[4991] - Implement `hpx::mem_fn`
- Issue #920[4992] - Output locality with `--hpx:print-bind`
- Issue #919[4993] - Correct grammar; simplify boolean expressions
- Issue #918[4994] - Link to hello_world.cpp is broken
- Issue #917[4995] - adapt cmake file to new boostbook version
- Issue #916[4996] - fix problem building documentation with xsltproc >= 1.1.27

- Issue #915[4997] - Add another TBBMalloc library search path
- Issue #914[4998] - Build problem with Intel compiler on Stampede (TACC)
- Issue #913[4999] - fix error messages in fibonacci examples
- Issue #911[5000] - Update OS X build instructions
- Issue #910[5001] - Want like to specify MPI_ROOT instead of compiler wrapper script
- Issue #909[5002] - Warning about void* arithmetic
- Issue #908[5003] - Buildbot for MIC is broken
- Issue #906[5004] - Can't use `--hpx:bind=balanced` with multiple MPI processes
- Issue #905[5005] - `--hpx:bind` documentation should describe full grammar
- Issue #904[5006] - Add hpx::lcos::fold and hpx::lcos::inverse_fold collective operation
- Issue #903[5007] - Add `hpx::when_any_swapped()`
- Issue #902[5008] - Add `hpx::lcos::reduce` collective operation
- Issue #901[5009] - Web documentation is not searchable
- Issue #900[5010] - Web documentation for trunk has no index
- Issue #898[5011] - Some tests fail with GCC 4.8.1 and MPI parcel port
- Issue #897[5012] - HWLOC causes failures on Mac
- Issue #896[5013] - pu-offset leads to startup error
- Issue #895[5014] - `hpx::get_locality_name` not defined
- Issue #894[5015] - Race condition at shutdown
- Issue #893[5016] - `--hpx:print-bind` switches std::cout to hexadecimal mode
- Issue #892[5017] - `hwloc_topology_load` can be expensive – don't call multiple times
- Issue #891[5018] - The documentation for `get_locality_name` is wrong
- Issue #890[5019] - `--hpx:print-bind` should not exit

- Issue #889[5020] - `--hpx:debug-hpx-log=FILE` does not work
- Issue #888[5021] - MPI parcelport does not exit cleanly for –hpx:print-bind
- Issue #887[5022] - Choose thread affinities more cleverly
- Issue #886[5023] - Logging documentation is confusing
- Issue #885[5024] - Two threads are slower than one
- Issue #884[5025] - is_callable failing with member pointers in C++11
- Issue #883[5026] - Need help with is_callable_test
- Issue #882[5027] - tests.regressions.lcos.future_hang_on_get does not terminate
- Issue #881[5028] - tests/regressions/block_matrix/matrix.hh won't compile with GCC 4.8.1
- Issue #880[5029] - HPX does not work on OS X
- Issue #878[5030] - `future::unwrap` triggers assertion
- Issue #877[5031] - "make tests" has build errors on Ubuntu 12.10
- Issue #876[5032] - tcmalloc is used by default, even if it is not present
- Issue #875[5033] - global_fixture is defined in a header file
- Issue #874[5034] - Some tests take very long
- Issue #873[5035] - Add block-matrix code as regression test
- Issue #872[5036] - HPX documentation does not say how to run tests with detailed output
- Issue #871[5037] - All tests fail with "make test"
- Issue #870[5038] - Please explicitly disable serialization in classes that don't support it
- Issue #868[5039] - boost_any test failing
- Issue #867[5040] - Reduce the number of copies of `hpx::function` arguments
- Issue #863[5041] - Futures should not require a default constructor
- Issue #862[5042] - value_or_error shall not default construct its result

[5065] https://github.com/STEllAR-GROUP/hpx/issues/832

- Issue #831[5066] - Arithmetics counter fails if only one parameter is given
- Issue #830[5067] - Convert hpx::util::function to use new scheme for serializing its base pointer
- Issue #829[5068] - Consistently use `decay<T>` instead of `remove_const< remove_reference<T>>`
- Issue #828[5069] - Update future implementation to N3721 and N3722
- Issue #827[5070] - Enable MPI parcelport for bootstrapping whenever application was started using mpirun
- Issue #826[5071] - Support command line option `--hpx:print-bind` even if `--hpx::bind` was not used
- Issue #825[5072] - Memory counters give segfault when attempting to use thread wild cards or numbers only total works
- Issue #824[5073] - Enable lambda functions to be used with hpx::async/hpx::apply
- Issue #823[5074] - Using a hashing filter
- Issue #822[5075] - Silence unused variable warning
- Issue #821[5076] - Detect if a function object is callable with given arguments
- Issue #820[5077] - Allow wildcards to be used for performance counter names
- Issue #819[5078] - Make the AGAS symbolic name registry distributed
- Issue #818[5079] - Add future::then() overload taking an executor
- Issue #817[5080] - Fixed typo
- Issue #815[5081] - Create an lco that is performing an efficient broadcast of actions
- Issue #814[5082] - Papi counters cannot specify thread#* to get the counts for all threads
- Issue #813[5083] - Scoped unlock
- Issue #811[5084] - simple_central_tuplespace_client run error
- Issue #810[5085] - ostream error when << any objects
- Issue #809[5086] - Optimize parcel serialization
- Issue #808[5087] - HPX applications throw exception when executed from the build directory
- Issue #807[5088] - Create performance counters exposing overall AGAS statistics

- Issue #795[5089] - Create timed make_ready_future
- Issue #794[5090] - Create heterogeneous `when_all`/`when_any`/etc.
- Issue #721[5091] - Make HPX usable for Xeon Phi
- Issue #694[5092] - CMake should complain if you attempt to build an example without its dependencies
- Issue #692[5093] - SLURM support broken
- Issue #683[5094] - python/hpx/process.py imports epoll on all platforms
- Issue #619[5095] - Automate the doc building process
- Issue #600[5096] - GTC performance broken
- Issue #577[5097] - Allow for zero copy serialization/networking
- Issue #551[5098] - Change executable names to have debug postfix in Debug builds
- Issue #544[5099] - Write a custom .lib file on Windows pulling in hpx_init and hpx.dll, phase out hpx_init
- Issue #534[5100] - `hpx::init` should take functions by `std::function` and should accept all forms of hpx_main
- Issue #508[5101] - FindPackage fails to set FOO_LIBRARY_DIR
- Issue #506[5102] - Add cmake support to generate ini files for external applications
- Issue #470[5103] - Changing build-type after configure does not update boost library names
- Issue #453[5104] - Document `hpx_run_tests.py`
- Issue #445[5105] - Significant performance mismatch between MPI and HPX in SMP for allgather example
- Issue #443[5106] - Make docs viewable from build directory
- Issue #421[5107] - Support multiple HPX instances per node in a batch environment like PBS or SLURM
- Issue #316[5108] - Add message size limitation
- Issue #249[5109] - Clean up locking code in big boot barrier
- Issue #136[5110] - Persistent CMake variables need to be marked as cache variables

2.10.20 *HPX* V0.9.6 (Jul 30, 2013)

We have had over 1200 commits since the last release and we have closed roughly 140 tickets (bugs, feature requests, etc.).

General changes

The major new features in this release are:

- We further consolidated the API exposed by *HPX*. We aligned our APIs as much as possible with the existing C++11 Standard[5111] and related proposals to the C++ standardization committee (such as N3632[5112] and N3857[5113]).
- We implemented a first version of a distributed AGAS service which essentially eliminates all explicit AGAS network traffic.
- We created a native ibverbs parcelport allowing to take advantage of the superior latency and bandwidth characteristics of Infiniband networks.
- We successfully ported *HPX* to the Xeon Phi platform.
- Support for the SLURM scheduling system was implemented.
- Major efforts have been dedicated to improving the performance counter framework, numerous new counters were implemented and new APIs were added.
- We added a modular parcel compression system allowing to improve bandwidth utilization (by reducing the overall size of the transferred data).
- We added a modular parcel coalescing system allowing to combine several parcels into larger messages. This reduces latencies introduced by the communication layer.
- Added an experimental executors API allowing to use different scheduling policies for different parts of the code. This API has been modelled after the Standards proposal N3562[5114]. This API is bound to change in the future, though.
- Added minimal security support for localities which is enforced on the parcelport level. This support is preliminary and experimental and might change in the future.
- We created a parcelport using low level MPI functions. This is in support of legacy applications which are to be gradually ported and to support platforms where MPI is the only available portable networking layer.
- We added a preliminary and experimental implementation of a tuple-space object which exposes an interface similar to such systems described in the literature (see for instance The Linda Coordination Language[5115]).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release. This is again a very long list of newly implemented features and fixed issues.

- Issue #806[5116] - make (all) in examples folder does nothing
- Issue #805[5117] - Adding the introduction and fixing DOCBOOK dependencies for Windows use
- Issue #804[5118] - Add stackless (non-suspendable) thread type
- Issue #803[5119] - Create proper serialization support functions for util::tuple
- Issue #800[5120] - Add possibility to disable array optimizations during serialization
- Issue #798[5121] - HPX_LIMIT does not work for local dataflow
- Issue #797[5122] - Create a parcelport which uses MPI
- Issue #796[5123] - Problem with Large Numbers of Threads
- Issue #793[5124] - Changing dataflow test case to hang consistently
- Issue #792[5125] - CMake Error
- Issue #791[5126] - Problems with local::dataflow
- Issue #790[5127] - wait_for() doesn't compile
- Issue #789[5128] - HPX with Intel compiler segfaults
- Issue #788[5129] - Intel compiler support
- Issue #787[5130] - Fixed SFINAEd specializations
- Issue #786[5131] - Memory issues during benchmarking.
- Issue #785[5132] - Create an API allowing to register external threads with HPX
- Issue #784[5133] - util::plugin is throwing an error when a symbol is not found
- Issue #783[5134] - How does hpx:bind work?
- Issue #782[5135] - Added quotes around STRING REPLACE potentially empty arguments
- Issue #781[5136] - Make sure no exceptions propagate into the thread manager

- Issue #780[5137] - Allow arithmetics performance counters to expand its parameters
- Issue #779[5138] - Test case for 778
- Issue #778[5139] - Swapping futures segfaults
- Issue #777[5140] - hpx::lcos::details::when_xxx don't restore completion handlers
- Issue #776[5141] - Compiler chokes on dataflow overload with launch policy
- Issue #775[5142] - Runtime error with local dataflow (copying futures?)
- Issue #774[5143] - Using local dataflow without explicit namespace
- Issue #773[5144] - Local dataflow with unwrap: functor operators need to be const
- Issue #772[5145] - Allow (remote) actions to return a future
- Issue #771[5146] - Setting HPX_LIMIT gives huge boost MPL errors
- Issue #770[5147] - Add launch policy to (local) dataflow
- Issue #769[5148] - Make compile time configuration information available
- Issue #768[5149] - Const correctness problem in local dataflow
- Issue #767[5150] - Add launch policies to async
- Issue #766[5151] - Mark data structures for optimized (array based) serialization
- Issue #765[5152] - Align hpx::any with N3508: Any Library Proposal (Revision 2)
- Issue #764[5153] - Align hpx::future with newest N3558: A Standardized Representation of Asynchronous Operations
- Issue #762[5154] - added a human readable output for the ping pong example
- Issue #761[5155] - Ambiguous typename when constructing derived component
- Issue #760[5156] - Simple components can not be derived
- Issue #759[5157] - make install doesn't give a complete install
- Issue #758[5158] - Stack overflow when using locking_hook<>
- Issue #757[5159] - copy paste error; unsupported function overloading

- Issue #756[5160] - GTCX runtime issue in Gordon
- Issue #755[5161] - Papi counters don't work with reset and evaluate API's
- Issue #753[5162] - cmake bugfix and improved component action docs
- Issue #752[5163] - hpx simple component docs
- Issue #750[5164] - Add hpx::util::any
- Issue #749[5165] - Thread phase counter is not reset
- Issue #748[5166] - Memory performance counter are not registered
- Issue #747[5167] - Create performance counters exposing arithmetic operations
- Issue #745[5168] - apply_callback needs to invoke callback when applied locally
- Issue #744[5169] - CMake fixes
- Issue #743[5170] - Problem Building github version of HPX
- Issue #742[5171] - Remove HPX_STD_BIND
- Issue #741[5172] - assertion 'px != 0' failed: HPX(assertion_failure) for low numbers of OS threads
- Issue #739[5173] - Performance counters do not count to the end of the program or evaluation
- Issue #738[5174] - Dedicated AGAS server runs don't work; console ignores -a option.
- Issue #737[5175] - Missing bind overloads
- Issue #736[5176] - Performance counter wildcards do not always work
- Issue #735[5177] - Create native ibverbs parcelport based on rdma operations
- Issue #734[5178] - Threads stolen performance counter total is incorrect
- Issue #733[5179] - Test benchmarks need to be checked and fixed
- Issue #732[5180] - Build fails with Mac, using mac ports clang-3.3 on latest git branch
- Issue #731[5181] - Add global start/stop API for performance counters
- Issue #730[5182] - Performance counter values are apparently incorrect

- Issue #729[5183] - Unhandled switch
- Issue #728[5184] - Serialization of hpx::util::function between two localities causes seg faults
- Issue #727[5185] - Memory counters on Mac OS X
- Issue #725[5186] - Restore original thread priority on resume
- Issue #724[5187] - Performance benchmarks do not depend on main HPX libraries
- Issue #723[5188] - [teletype]–hpx:nodes=``cat $PBS_NODEFILE`` works; –hpx:nodefile=$PBS_NODEFILE does not.[c++]
- Issue #722[5189] - Fix binding const member functions as actions
- Issue #719[5190] - Create performance counter exposing compression ratio
- Issue #718[5191] - Add possibility to compress parcel data
- Issue #717[5192] - strip_credit_from_gid has misleading semantics
- Issue #716[5193] - Non-option arguments to programs run using `pbsdsh` must be before `--hpx:nodes`, contrary to directions
- Issue #715[5194] - Re-thrown exceptions should retain the original call site
- Issue #714[5195] - failed assertion in debug mode
- Issue #713[5196] - Add performance counters monitoring connection caches
- Issue #712[5197] - Adjust parcel related performance counters to be connection type specific
- Issue #711[5198] - configuration failure
- Issue #710[5199] - Error "timed out while trying to find room in the connection cache" when trying to start multiple localities on a single computer
- Issue #709[5200] - Add new thread state 'staged' referring to task descriptions
- Issue #708[5201] - Detect/mitigate bad non-system installs of GCC on Redhat systems
- Issue #707[5202] - Many examples do not link with Git HEAD version
- Issue #706[5203] - `hpx::init` removes portions of non-option command line arguments before last = sign
- Issue #705[5204] - Create rolling average and median aggregating performance counters

[5204] https://github.com/STEllAR-GROUP/hpx/issues/705

- Issue #704[5205] - Create performance counter to expose thread queue waiting time
- Issue #703[5206] - Add support to HPX build system to find librcrtool.a and related headers
- Issue #699[5207] - Generalize instrumentation support
- Issue #698[5208] - compilation failure with hwloc absent
- Issue #697[5209] - Performance counter counts should be zero indexed
- Issue #696[5210] - Distributed problem
- Issue #695[5211] - Bad perf counter time printed
- Issue #693[5212] - `--help` doesn't print component specific command line options
- Issue #692[5213] - SLURM support broken
- Issue #691[5214] - exception while executing any application linked with hwloc
- Issue #690[5215] - thread_id_test and thread_launcher_test failing
- Issue #689[5216] - Make the buildbots use hwloc
- Issue #687[5217] - compilation error fix (hwloc_topology)
- Issue #686[5218] - Linker Error for Applications
- Issue #684[5219] - Pinning of service thread fails when number of worker threads equals the number of cores
- Issue #682[5220] - Add performance counters exposing number of stolen threads
- Issue #681[5221] - Add apply_continue for asynchronous chaining of actions
- Issue #679[5222] - Remove obsolete async_callback API functions
- Issue #678[5223] - Add new API for setting/triggering LCOs
- Issue #677[5224] - Add async_continue for true continuation style actions
- Issue #676[5225] - Buildbot for gcc 4.4 broken
- Issue #675[5226] - Partial preprocessing broken
- Issue #674[5227] - HPX segfaults when built with gcc 4.7

- Issue #341[5252] - Consolidate route code
- Issue #219[5253] - Only copy arguments into actions once
- Issue #177[5254] - Implement distributed AGAS
- Issue #43[5255] - Support for Darwin (Xcode + Clang)

2.10.21 *HPX* V0.9.5 (Jan 16, 2013)

We have had over 1000 commits since the last release and we have closed roughly 150 tickets (bugs, feature requests, etc.).

General changes

This release is continuing along the lines of code and API consolidation, and overall usability inprovements. We dedicated much attention to performance and we were able to significantly improve the threading and networking subsystems.

We successfully ported *HPX* to the Android platform. *HPX* applications now not only can run on mobile devices, but we support heterogeneous applications running across architecture boundaries. At the Supercomputing Conference 2012 we demonstrated connecting Android tablets to simulations running on a Linux cluster. The Android tablet was used to query performance counters from the Linux simulation and to steer its parameters.

We successfully ported *HPX* to Mac OSX (using the Clang compiler). Thanks to Pyry Jahkola for contributing the corresponding patches. Please see the section macos_installation for more details.

We made a special effort to make HPX usable in highly concurrent use cases. Many of the HPX API functions which possibly take longer than 100 microseconds to execute now can be invoked asynchronously. We added uniform support for composing futures which simplifies to write asynchronous code. HPX actions (function objects encapsulating possibly concurrent remote function invocations) are now well integrated with all other API facilities such like `hpx::bind`.

All of the API has been aligned as much as possible with established paradigms. HPX now mirrors many of the facilities as defined in the C++11 Standard, such as `hpx::thread`, `hpx::function`, `hpx::future`, etc.

A lot of work has been put into improving the documentation. Many of the API functions are documented now, concepts are explained in detail, and examples are better described than before. The new documentation index enables finding information with lesser effort.

This is the first release of HPX we perform after the move to Github[5256] This step has enabled a wider participation from the community and further encourages us in our decision to release HPX as a true open source library (HPX is licensed under the very liberal Boost Software License[5257]).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release. This is by far the longest list of newly implemented features and fixed issues for any of HPX' releases so far.

- Issue #666[5258] - Segfault on calling hpx::finalize twice
- Issue #665[5259] - Adding declaration num_of_cores
- Issue #662[5260] - pkgconfig is building wrong
- Issue #660[5261] - Need uninterrupt function
- Issue #659[5262] - Move our logging library into a different namespace
- Issue #658[5263] - Dynamic performance counter types are broken
- Issue #657[5264] - HPX v0.9.5 (RC1) hello_world example segfaulting
- Issue #656[5265] - Define the affinity of parcel-pool, io-pool, and timer-pool threads
- Issue #654[5266] - Integrate the Boost auto_index tool with documentation
- Issue #653[5267] - Make HPX build on OS X + Clang + libc++
- Issue #651[5268] - Add fine-grained control for thread pinning
- Issue #650[5269] - Command line no error message when using -hpx:(anything)
- Issue #645[5270] - Command line aliases don't work in [teletype]``@file``[c++]
- Issue #644[5271] - Terminated threads are not always properly cleaned up
- Issue #640[5272] - `future_data<T>::set_on_completed_` used without locks
- Issue #638[5273] - hpx build with intel compilers fails on linux
- Issue #637[5274] - –copy-dt-needed-entries breaks with gold
- Issue #635[5275] - Boost V1.53 will add Boost.Lockfree and Boost.Atomic
- Issue #633[5276] - Re-add examples to final 0.9.5 release
- Issue #632[5277] - Example `thread_aware_timer` is broken
- Issue #631[5278] - FFT application throws error in parcellayer

- Issue #630[5279] - Event synchronization example is broken
- Issue #629[5280] - Waiting on futures hangs
- Issue #628[5281] - Add an `HPX_ALWAYS_ASSERT` macro
- Issue #625[5282] - Port coroutines context switch benchmark
- Issue #621[5283] - New INI section for stack sizes
- Issue #618[5284] - pkg_config support does not work with a HPX debug build
- Issue #617[5285] - hpx/external/logging/boost/logging/detail/cache_before_init.hpp:139:67: error: 'get_thread_id' was not declared in this scope
- Issue #616[5286] - Change wait_xxx not to use locking
- Issue #615[5287] - Revert visibility 'fix' (fb0b6b8245dad1127b0c25ebafd9386b3945cca9)
- Issue #614[5288] - Fix Dataflow linker error
- Issue #613[5289] - find_here should throw an exception on failure
- Issue #612[5290] - Thread phase doesn't show up in debug mode
- Issue #611[5291] - Make stack guard pages configurable at runtime (initialization time)
- Issue #610[5292] - Co-Locate Components
- Issue #609[5293] - future_overhead
- Issue #608[5294] - `--hpx:list-counter-infos` problem
- Issue #607[5295] - Update Boost.Context based backend for coroutines
- Issue #606[5296] - 1d_wave_equation is not working
- Issue #605[5297] - Any C++ function that has serializable arguments and a serializable return type should be remotable
- Issue #604[5298] - Connecting localities isn't working anymore
- Issue #603[5299] - Do not verify any ini entries read from a file
- Issue #602[5300] - Rename argument_size to type_size/ added implementation to get parcel size

- Issue #599[5301] - Enable locality specific command line options
- Issue #598[5302] - Need an API that accesses the performance counter reporting the system uptime
- Issue #597[5303] - compiling on ranger
- Issue #595[5304] - I need a place to store data in a thread self pointer
- Issue #594[5305] - 32/64 interoperability
- Issue #593[5306] - Warn if logging is disabled at compile time but requested at runtime
- Issue #592[5307] - Add optional argument value to `--hpx:list-counters` and `--hpx:list-counter-infos`
- Issue #591[5308] - Allow for wildcards in performance counter names specified with `--hpx:print-counter`
- Issue #590[5309] - Local promise semantic differences
- Issue #589[5310] - Create API to query performance counter names
- Issue #587[5311] - Add get_num_localities and get_num_threads to AGAS API
- Issue #586[5312] - Adjust local AGAS cache size based on number of localities
- Issue #585[5313] - Error while using counters in HPX
- Issue #584[5314] - counting argument size of actions, initial pass.
- Issue #581[5315] - Remove `RemoteResult` template parameter for `future<>`
- Issue #580[5316] - Add possibility to hook into actions
- Issue #578[5317] - Use angle brackets in HPX error dumps
- Issue #576[5318] - Exception incorrectly thrown when `--help` is used
- Issue #575[5319] - HPX(bad_component_type) with gcc 4.7.2 and boost 1.51
- Issue #574[5320] - `--hpx:connect` command line parameter not working correctly
- Issue #571[5321] - `hpx::wait()` (callback version) should pass the future to the callback function
- Issue #570[5322] - `hpx::wait` should operate on `boost::arrays` and `std::lists`
- Issue #569[5323] - Add a logging sink for Android

- Issue #568[5324] - 2-argument version of `HPX_DEFINE_COMPONENT_ACTION`
- Issue #567[5325] - Connecting to a running HPX application works only once
- Issue #565[5326] - HPX doesn't shutdown properly
- Issue #564[5327] - Partial preprocessing of new component creation interface
- Issue #563[5328] - Add `hpx::start`/`hpx::stop` to avoid blocking main thread
- Issue #562[5329] - All command line arguments swallowed by hpx
- Issue #561[5330] - Boost.Tuple is not move aware
- Issue #558[5331] - `boost::shared_ptr<>` style semantics/syntax for client classes
- Issue #556[5332] - Creation of partially preprocessed headers should be enabled for Boost newer than V1.50
- Issue #555[5333] - `BOOST_FORCEINLINE` does not name a type
- Issue #554[5334] - Possible race condition in thread `get_id()`
- Issue #552[5335] - Move enable client_base
- Issue #550[5336] - Add stack size category 'huge'
- Issue #549[5337] - ShenEOS run seg-faults on single or distributed runs
- Issue #545[5338] - `AUTOGLOB` broken for add_hpx_component
- Issue #542[5339] - FindHPX_HDF5 still searches multiple times
- Issue #541[5340] - Quotes around application name in hpx::init
- Issue #539[5341] - Race condititition occurring with new lightweight threads
- Issue #535[5342] - hpx_run_tests.py exits with no error code when tests are missing
- Issue #530[5343] - Thread description(<unknown>) in logs
- Issue #523[5344] - Make thread objects more lightweight
- Issue #521[5345] - `hpx::error_code` is not usable for lightweight error handling
- Issue #520[5346] - Add full user environment to HPX logs

- Issue #519[5347] - Build succeeds, running fails
- Issue #517[5348] - Add a guard page to linux coroutine stacks
- Issue #516[5349] - hpx::thread::detach suspends while holding locks, leads to hang in debug
- Issue #514[5350] - Preprocessed headers for <hpx/apply.hpp> don't compile
- Issue #513[5351] - Buildbot configuration problem
- Issue #512[5352] - Implement action based stack size customization
- Issue #511[5353] - Move action priority into a separate type trait
- Issue #510[5354] - trunk broken
- Issue #507[5355] - no matching function for call to `boost::scoped_ptr<hpx::threads::topology>::scoped_ptr(h`
- Issue #505[5356] - undefined_symbol regression test currently failing
- Issue #502[5357] - Adding OpenCL and OCLM support to HPX for Windows and Linux
- Issue #501[5358] - find_package(HPX) sets cmake output variables
- Issue #500[5359] - wait_any/wait_all are badly named
- Issue #499[5360] - Add support for disabling pbs support in pbs runs
- Issue #498[5361] - Error during no-cache runs
- Issue #496[5362] - Add partial preprocessing support to cmake
- Issue #495[5363] - Support HPX modules exporting startup/shutdown functions only
- Issue #494[5364] - Allow modules to specify when to run startup/shutdown functions
- Issue #493[5365] - Avoid constructing a string in make_success_code
- Issue #492[5366] - Performance counter creation is no longer synchronized at startup
- Issue #491[5367] - Performance counter creation is no longer synchronized at startup
- Issue #490[5368] - Sheneos on_completed_bulk seg fault in distributed
- Issue #489[5369] - compiling issue with g++44

- Issue #488[5370] - Adding OpenCL and OCLM support to HPX for the MSVC platform
- Issue #487[5371] - FindHPX.cmake problems
- Issue #485[5372] - Change distributing_factory and binpacking_factory to use bulk creation
- Issue #484[5373] - Change `HPX_DONT_USE_PREPROCESSED_FILES` to `HPX_USE_PREPROCESSED_FILES`
- Issue #483[5374] - Memory counter for Windows
- Issue #479[5375] - strange errors appear when requesting performance counters on multiple nodes
- Issue #477[5376] - Create (global) timer for multi-threaded measurements
- Issue #472[5377] - Add partial preprocessing using Wave
- Issue #471[5378] - Segfault stack traces don't show up in release
- Issue #468[5379] - External projects need to link with internal components
- Issue #462[5380] - Startup/shutdown functions are called more than once
- Issue #458[5381] - Consolidate hpx::util::high_resolution_timer and `hpx::util::high_resolution_clock`
- Issue #457[5382] - index out of bounds in `allgather_and_gate` on 4 cores or more
- Issue #448[5383] - Make HPX compile with clang
- Issue #447[5384] - 'make tests' should execute tests on local installation
- Issue #446[5385] - Remove SVN-related code from the codebase
- Issue #444[5386] - race condition in smp
- Issue #441[5387] - Patched Boost.Serialization headers should only be installed if needed
- Issue #439[5388] - Components using `HPX_REGISTER_STARTUP_MODULE` fail to compile with MSVC
- Issue #436[5389] - Verify that no locks are being held while threads are suspended
- Issue #435[5390] - Installing HPX should not clobber existing Boost installation
- Issue #434[5391] - Logging external component failed (Boost 1.50)
- Issue #433[5392] - Runtime crash when building all examples

2.10.22 *HPX* V0.9.0 (Jul 5, 2012)

We have had roughly 800 commits since the last release and we have closed approximately 80 tickets (bugs, feature requests, etc.).

General changes

- Significant improvements made to the usability of *HPX* in large-scale, distributed environments.
- Renamed `hpx::lcos::packaged_task` to *`hpx::lcos::packaged_action`* to reflect the semantic differences to a packaged_task as defined by the C++11 Standard[5414].
- *HPX* now exposes *`hpx::thread`* which is compliant to the C++11 std::thread type except that it (purely locally) represents an *HPX* thread. This new type does not expose any of the remote capabilities of the underlying *HPX*-thread implementation.
- The type `hpx::lcos::future` is now compliant to the C++11 std::future<> type. This type can be used to synchronize both, local and remote operations. In both cases the control flow will 'return' to the future in order to trigger any continuation.
- The types `hpx::lcos::local::promise` and `hpx::lcos::local::packaged_task` are now compliant to the C++11 `std::promise<>` and `std::packaged_task<>` types. These can be used to create a future representing local work only. Use the types `hpx::lcos::promise` and *`hpx::lcos::packaged_action`* to wrap any (possibly remote) action into a future.
- *`hpx::thread`* and `hpx::lcos::future` are now cancelable.
- Added support for sequential and logic composition of `hpx::lcos::futures`. The member function `hpx::lcos::future::when` permits futures to be sequentially composed. The helper functions *`hpx::wait_all`*, *`hpx::wait_any`*, and `hpx::wait_n` can be used to wait for more than one future at a time.
- *HPX* now exposes *`hpx::apply`* and *`hpx::async`* as the preferred way of creating (or invoking) any deferred work. These functions are usable with various types of functions, function objects, and actions and provide a uniform way to spawn deferred tasks.
- *HPX* now utilizes `hpx::util::bind` to (partially) bind local functions and function objects, and also actions. Remote bound actions can have placeholders as well.
- *HPX* continuations are now fully polymorphic. The class `hpx::actions::forwarding_continuation` is an example of how the user can write is own types of continuations. It can be used to execute any function as an continuation of a particular action.
- Reworked the action invocation API to be fully conformant to normal functions. Actions can now be invoked using *`hpx::apply`*, *`hpx::async`*, or using the `operator()` implemented on actions. Actions themselves can now be cheaply instantiated as they do not have any members anymore.
- Reworked the lazy action invocation API. Actions can now be directly bound using `hpx::util::bind` by passing an action instance as the first argument.
- A minimal *HPX* program now looks like this:

```
#include <hpx/hpx_init.hpp>

int hpx_main()
{
    return hpx::finalize();
```

(continues on next page)

[5414] http://www.open-std.org/jtc1/sc22/wg21

(continued from previous page)

```
}

int main()
{
    return hpx::init();
}
```

This removes the immediate dependency on the Boost.Program Options[5415] library.

Note: This minimal version of an *HPX* program does not support any of the default command line arguments (such as –help, or command line options related to PBS). It is suggested to always pass `argc` and `argv` to *HPX* as shown in the example below.

- In order to support those, but still not to depend on Boost.Program Options[5416], the minimal program can be written as:

```
#include <hpx/hpx_init.hpp>

// The arguments for hpx_main can be left off, which very similar to the
// behavior of ``main()`` as defined by C++.
int hpx_main(int argc, char* argv[])
{
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```

- Added performance counters exposing the number of component instances which are alive on a given locality.
- Added performance counters exposing then number of messages sent and received, the number of parcels sent and received, the number of bytes sent and received, the overall time required to send and receive data, and the overall time required to serialize and deserialize the data.
- Added a new component: `hpx::components::binpacking_factory` which is equivalent to the existing `hpx::components::distributing_factory` component, except that it equalizes the overall population of the components to create. It exposes two factory methods, one based on the number of existing instances of the component type to create, and one based on an arbitrary performance counter which will be queried for all relevant localities.
- Added API functions allowing to access elements of the diagnostic information embedded in the given exception: *`hpx::get_locality_id`*, `hpx::get_host_name`, `hpx::get_process_id`, `hpx::get_function_name`, `hpx::get_file_name`, `hpx::get_line_number`, `hpx::get_os_thread`, `hpx::get_thread_id`, and `hpx::get_thread_description`.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #71[5417] - GIDs that are not serialized via `handle_gid<>` should raise an exception
- Issue #105[5418] - Allow for `hpx::util::functions` to be registered in the AGAS symbolic namespace
- Issue #107[5419] - Nasty threadmanger race condition (reproducible in sheneos_test)
- Issue #108[5420] - Add millisecond resolution to *HPX* logs on Linux
- Issue #110[5421] - Shutdown hang in distributed with release build
- Issue #116[5422] - Don't use TSS for the applier and runtime pointers
- Issue #162[5423] - Move local synchronous execution shortcut from hpx::function to the applier
- Issue #172[5424] - Cache sources in CMake and check if they change manually
- Issue #178[5425] - Add an INI option to turn off ranged-based AGAS caching
- Issue #187[5426] - Support for disabling performance counter deployment
- Issue #202[5427] - Support for sending performance counter data to a specific file
- Issue #218[5428] - boost.coroutines allows different stack sizes, but stack pool is unaware of this
- Issue #231[5429] - Implement movable `boost::bind`
- Issue #232[5430] - Implement movable `boost::function`
- Issue #236[5431] - Allow binding `hpx::util::function` to actions
- Issue #239[5432] - Replace `hpx::function` with `hpx::util::function`
- Issue #240[5433] - Can't specify RemoteResult with lcos::async
- Issue #242[5434] - REGISTER_TEMPLATE support for plain actions
- Issue #243[5435] - `handle_gid<>` support for `hpx::util::function`
- Issue #245[5436] - `*_c_cache code` throws an exception if the queried GID is not in the local cache
- Issue #246[5437] - Undefined references in dataflow/adaptive1d example

- Issue #252[5438] - Problems configuring sheneos with CMake
- Issue #254[5439] - Lifetime of components doesn't end when client goes out of scope
- Issue #259[5440] - CMake does not detect that MSVC10 has lambdas
- Issue #260[5441] - io_service_pool segfault
- Issue #261[5442] - Late parcel executed outside of pxthread
- Issue #263[5443] - Cannot select allocator with CMake
- Issue #264[5444] - Fix allocator select
- Issue #267[5445] - Runtime error for hello_world
- Issue #269[5446] - pthread_affinity_np test fails to compile
- Issue #270[5447] - Compiler noise due to -Wcast-qual
- Issue #275[5448] - Problem with configuration tests/include paths on Gentoo
- Issue #325[5449] - Sheneos is 200-400 times slower than the fortran equivalent
- Issue #331[5450] - *`hpx::init`* and `hpx_main()` should not depend on program_options
- Issue #333[5451] - Add doxygen support to CMake for doc toolchain
- Issue #340[5452] - Performance counters for parcels
- Issue #346[5453] - Component loading error when running hello_world in distributed on MSVC2010
- Issue #362[5454] - Missing initializer error
- Issue #363[5455] - Parcel port serialization error
- Issue #366[5456] - Parcel buffering leads to types incompatible exception
- Issue #368[5457] - Scalable alternative to rand() needed for *HPX*
- Issue #369[5458] - IB over IP is substantially slower than just using standard TCP/IP
- Issue #374[5459] - `hpx::lcos::wait` should work with dataflows and arbitrary classes meeting the future interface
- Issue #375[5460] - Conflicting/ambiguous overloads of `hpx::lcos::wait`

General changes

- *HPX* does not need to be installed anymore to be functional.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this point release:

- Issue #295[5479] - Don't require install path to be known at compile time.
- Issue #371[5480] - Add hpx iostreams to standard build.
- Issue #384[5481] - Fix compilation with GCC 4.7.
- Issue #390[5482] - Remove keep_factory_alive startup call from ShenEOS; add shutdown call to H5close.
- Issue #393[5483] - Thread affinity control is broken.

Bug fixes (commits)

Here is a list of the important commits included in this point release:

- r7642 - External: Fix backtrace memory violation.
- **r7775 - Components: Fix symbol visibility bug with component startup** providers. This prevents one components providers from overriding another components.
- r7778 - Components: Fix startup/shutdown provider shadowing issues.

2.10.24 *HPX* V0.8.0 (Mar 23, 2012)

We have had roughly 1000 commits since the last release and we have closed approximately 70 tickets (bugs, feature requests, etc.).

General changes

- Improved PBS support, allowing for arbitrary naming schemes of node-hostnames.
- Finished verification of the reference counting framework.
- Implemented decrement merging logic to optimize the distributed reference counting system.
- Restructured the LCO framework. Renamed `hpx::lcos::eager_future<>` and `hpx::lcos::lazy_future<>` into `hpx::lcos::packaged_task` and `hpx::lcos::deferred_packaged_task`. Split `hpx::lcos::promise` into `hpx::lcos::packaged_task` and `hpx::lcos::future`. Added 'local' futures (in namespace `hpx::lcos::local`).
- Improved the general performance of local and remote action invocations. This (under certain circumstances) drastically reduces the number of copies created for each of the parameters and return values.

[5479] https://github.com/STEllAR-GROUP/hpx/issues/295
[5480] https://github.com/STEllAR-GROUP/hpx/issues/371
[5481] https://github.com/STEllAR-GROUP/hpx/issues/384
[5482] https://github.com/STEllAR-GROUP/hpx/issues/390
[5483] https://github.com/STEllAR-GROUP/hpx/issues/393

- Reworked the performance counter framework. Performance counters are now created only when needed, which reduces the overall resource requirements. The new framework allows for much more flexible creation and management of performance counters. The new sine example application demonstrates some of the capabilities of the new infrastructure.
- Added a buildbot-based continuous build system which gives instant, automated feedback on each commit to SVN.
- Added more automated tests to verify proper functioning of *HPX*.
- Started to create documentation for *HPX* and its API.
- Added documentation toolchain to the build system.
- Added dataflow LCO.
- Changed default *HPX* command line options to have `hpx:` prefix. For instance, the former option `--threads` is now `--hpx:threads`. This has been done to make ambiguities with possible application specific command line options as unlikely as possible. See the section *HPX Command Line Options* for a full list of available options.
- Added the possibility to define command line aliases. The former short (one-letter) command line options have been predefined as aliases for backwards compatibility. See the section *HPX Command Line Options* for a detailed description of command line option aliasing.
- Network connections are now cached based on the connected host. The number of simultaneous connections to a particular host is now limited. Parcels are buffered and bundled if all connections are in use.
- Added more refined thread affinity control. This is based on the external library Portable Hardware Locality (HWLOC).
- Improved support for Windows builds with CMake.
- Added support for components to register their own command line options.
- Added the possibility to register custom startup/shutdown functions for any component. These functions are guaranteed to be executed by an *HPX* thread.
- Added two new experimental thread schedulers: hierarchy_scheduler and periodic_priority_scheduler. These can be activated by using the command line options `--hpx:queuing=hierarchy` or `--hpx:queuing=periodic`.

Example applications

- Graph500 performance benchmark[5484] (thanks to Matthew Anderson for contributing this application).
- GTC (Gyrokinetic Toroidal Code)[5485]: a skeleton for particle in cell type codes.
- Random Memory Access: an example demonstrating random memory accesses in a large array
- ShenEOS example[5486], demonstrating partitioning of large read-only data structures and exposing an interpolation API.
- Sine performance counter demo.
- Accumulator examples demonstrating how to write and use *HPX* components.
- Quickstart examples (like hello_world, fibonacci, quicksort, factorial, etc.) demonstrating simple *HPX* concepts which introduce some of the concepts in *HPX*.

[5484] http://www.graph500.org/
[5485] http://www.nersc.gov/research-and-development/benchmarking-and-workload-characterization/nersc-6-benchmarks/gtc/
[5486] http://stellarcollapse.org/equationofstate

- Load balancing and work stealing demos.

API changes

- Moved all local LCOs into a separate namespace `hpx::lcos::local` (for instance, `hpx::lcos::local_mutex` is now *`hpx::lcos::local::mutex`*).
- Replaced `hpx::actions::function` with `hpx::util::function`. Cleaned up related code.
- Removed `hpx::traits::handle_gid` and moved handling of global reference counts into the corresponding serialization code.
- Changed terminology: `prefix` is now called `locality_id`, renamed the corresponding API functions (such as `hpx::get_prefix`, which is now called `hpx::get_locality_id`).
- Adding *`hpx::find_remote_localities`*, and *`hpx::get_num_localities`*.
- Changed performance counter naming scheme to make it more bash friendly. The new performance counter naming scheme is now

```
/object{parentname#parentindex/instance#index}/counter#parameters
```

- Added `hpx::get_worker_thread_num` replacing `hpx::threadmanager_base::get_thread_num`.
- Renamed `hpx::get_num_os_threads` to `hpx::get_os_threads_count`.
- Added `hpx::threads::get_thread_count`.
- Restructured the Futures sub-system, renaming types in accordance with the terminology used by the C++11 ISO standard.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #31[5487] - Specialize handle_gid<> for examples and tests
- Issue #72[5488] - Fix AGAS reference counting
- Issue #104[5489] - heartbeat throws an exception when decrefing the performance counter it's watching
- Issue #111[5490] - throttle causes an exception on the target application
- Issue #142[5491] - One failed component loading causes an unrelated component to fail
- Issue #165[5492] - Remote exception propagation bug in AGAS reference counting test
- Issue #186[5493] - Test credit exhaustion/splitting (e.g. prepare_gid and symbol NS)
- Issue #188[5494] - Implement remaining AGAS reference counting test cases
- Issue #258[5495] - No type checking of GIDs in stubs classes

[5534] https://github.com/STEllAR-GROUP/hpx/issues/361
[5535] https://github.com/STEllAR-GROUP/hpx/issues/364

General changes

- Completely removed code related to deprecated AGAS V1, started to work on AGAS V2.1.
- Started to clean up and streamline the exposed APIs (see 'API changes' below for more details).
- Revamped and unified performance counter framework, added a lot of new performance counter instances for monitoring of a diverse set of internal *HPX* parameters (queue lengths, access statistics, etc.).
- Improved general error handling and logging support.
- Fixed several race conditions, improved overall stability, decreased memory footprint, improved overall performance (major optimizations include native TLS support and ranged-based AGAS caching).
- Added support for running *HPX* applications with PBS.
- Many updates to the build system, added support for gcc 4.5.x and 4.6.x, added C++11 support.
- Many updates to default command line options.
- Added many tests, set up buildbot for continuous integration testing.
- Better shutdown handling of distributed applications.

Example applications

- quickstart/factorial and quickstart/fibonacci, future-recursive parallel algorithms.
- quickstart/hello_world, distributed hello world example.
- quickstart/rma, simple remote memory access example
- quickstart/quicksort, parallel quicksort implementation.
- gtc, gyrokinetic torodial code.
- bfs, breadth-first-search, example code for a graph application.
- sheneos, partitioning of large data sets.
- accumulator, simple component example.
- balancing/os_thread_num, balancing/px_thread_phase, examples demonstrating load balancing and work stealing.

API changes

- Added `hpx::find_all_localities`.
- Added `hpx::terminate` for non-graceful termination of applications.
- Added `hpx::lcos::async` functions for simpler asynchronous programming.
- Added new AGAS interface for handling of symbolic namespace (`hpx::agas::*`).
- Renamed `hpx::components::wait` to `hpx::lcos::wait`.
- Renamed `hpx::lcos::future_value` to `hpx::lcos::promise`.
- Renamed `hpx::lcos::recursive_mutex` to `hpx::lcos::local_recursive_mutex`, `hpx::lcos::mutex` to `hpx::lcos::local_mutex`
- Removed support for Boost versions older than V1.38, recommended Boost version is now V1.47 and newer.
- Removed `hpx::process` (this will be replaced by a real process implementation in the future).

- Removed non-functional LCO code (`hpx::lcos::dataflow`, `hpx::lcos::thunk`, `hpx::lcos::dataflow_variable`).
- Removed deprecated `hpx::naming::full_address`.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #28[5536] - Integrate Windows/Linux CMake code for *HPX* core
- Issue #32[5537] - hpx::cout() should be hpx::cout
- Issue #33[5538] - AGAS V2 legacy client does not properly handle error_code
- Issue #60[5539] - AGAS: allow for registerid to optionally take ownership of the gid
- Issue #62[5540] - adaptive1d compilation failure in Fusion
- Issue #64[5541] - Parcel subsystem doesn't resolve domain names
- Issue #83[5542] - No error handling if no console is available
- Issue #84[5543] - No error handling if a hosted locality is treated as the bootstrap server
- Issue #90[5544] - Add general commandline option -N
- Issue #91[5545] - Add possibility to read command line arguments from file
- Issue #92[5546] - Always log exceptions/errors to the log file
- Issue #93[5547] - Log the command line/program name
- Issue #95[5548] - Support for distributed launches
- Issue #97[5549] - Attempt to create a bad component type in AMR examples
- Issue #100[5550] - factorial and factorial_get examples trigger AGAS component type assertions
- Issue #101[5551] - Segfault when hpx::process::here() is called in fibonacci2
- Issue #102[5552] - unknown_component_address in int_object_semaphore_client
- Issue #114[5553] - marduk raises assertion with default parameters
- Issue #115[5554] - Logging messages for SMP runs (on the console) shouldn't be buffered

- Issue #228[5601] - Move all traits into namespace hpx::traits
- Issue #229[5602] - Invalid initialization of reference in thread_init_data
- Issue #235[5603] - Invalid GID in iostreams
- Issue #238[5604] - Demangle type names for the default implementation of get_action_name
- Issue #241[5605] - C++11 support breaks GCC 4.5
- Issue #247[5606] - Reference to temporary with GCC 4.4
- Issue #248[5607] - Seg fault at shutdown with GCC 4.4
- Issue #253[5608] - Default component action registration kills compiler
- Issue #272[5609] - G++ unrecognized command line option
- Issue #273[5610] - quicksort example doesn't compile
- Issue #277[5611] - Invalid CMake logic for Windows

2.11 Citing *HPX*

Please cite *HPX* whenever you use it for publications. Use our paper in The Journal of Open Source Software as the main citation for *HPX*: [5612]. Use the Zenodo entry for referring to the latest version of *HPX*: [5613]. Entries for citing specific versions of *HPX* can also be found at [5614].

2.12 *HPX* users

A list of institutions and projects using *HPX* can be found on the *HPX* Users[5615] page.

2.13 About *HPX*

2.13.1 History

The development of High Performance ParalleX (*HPX*) began in 2007. At that time, Hartmut Kaiser became interested in the work done by the ParalleX group at the Center for Computation and Technology (CCT)[5616], a multi-disciplinary research institute at Louisiana State University (LSU)[5617]. The ParalleX group was working to develop a new and

experimental execution model for future high performance computing architectures. This model was christened ParalleX. The first implementations of ParalleX were crude, and many of those designs had to be discarded entirely. However, over time the team learned quite a bit about how to design a parallel, distributed runtime system which implements the concepts of ParalleX.

From the very beginning, this endeavour has been a group effort. In addition to a handful of interested researchers, there have always been graduate and undergraduate students participating in the discussions, design, and implementation of *HPX*. In 2011 we decided to formalize our collective research efforts by creating the STE||AR[5618] group (**S**ystems **T**echnology, **E**mergent Para**ll**elism, and **A**lgorithm **R**esearch). Over time, the team grew to include researchers around the country and the world. In 2014, the STE||AR[5619] Group was reorganized to become the international community it is today. This consortium of researchers aims to develop stable, sustainable, and scalable tools which will enable application developers to exploit the parallelism latent in the machines of today and tomorrow. Our goal of the *HPX* project is to create a high quality, freely available, open source implementation of ParalleX concepts for conventional and future systems by building a modular and standards conforming runtime system for SMP and distributed application environments. The API exposed by *HPX* is conformant to the interfaces defined by the C++ ISO Standard and adheres to the programming guidelines used by the Boost[5620] collection of C++ libraries. We steer the development of *HPX* with real world applications and aim to provide a smooth migration path for domain scientists.

To learn more about STE||AR[5621] and ParalleX, see *People* and *Why HPX?*.

2.13.2 People

The STE||AR[5622] Group (pronounced as stellar) stands for "**S**ystems **T**echnology, **E**mergent Para**ll**elism, and **A**lgorithm **R**esearch". We are an international group of faculty, researchers, and students working at various institutions around the world. The goal of the STE||AR[5623] Group is to promote the development of scalable parallel applications by providing a community for ideas, a framework for collaboration, and a platform for communicating these concepts to the broader community.

Our work is focused on building technologies for scalable parallel applications. *HPX*, our general purpose C++ runtime system for parallel and distributed applications, is no exception. We use *HPX* for a broad range of scientific applications, helping scientists and developers to write code which scales better and shows better performance compared to more conventional programming models such as MPI.

HPX is based on *ParalleX* which is a new (and still experimental) parallel execution model aiming to overcome the limitations imposed by the current hardware and the techniques we use to write applications today. Our group focuses on two types of applications - those requiring excellent strong scaling, allowing for a dramatic reduction of execution time for fixed workloads and those needing highest level of sustained performance through massive parallelism. These applications are presently unable (through conventional practices) to effectively exploit a relatively small number of cores in a multi-core system. By extension, these application will not be able to exploit high-end exascale computing systems which are likely to employ hundreds of millions of such cores by the end of this decade.

Critical bottlenecks to the effective use of new generation high performance computing (HPC) systems include:

- *Starvation*: due to lack of usable application parallelism and means of managing it,
- *Overhead*: reduction to permit strong scalability, improve efficiency, and enable dynamic resource management,
- *Latency*: from remote access across system or to local memories,
- *Contention*: due to multicore chip I/O pins, memory banks, and system interconnects.

[5618] https://stellar-group.org
[5619] https://stellar-group.org
[5620] https://www.boost.org/
[5621] https://stellar-group.org
[5622] https://stellar-group.org
[5623] https://stellar-group.org

The ParalleX model has been devised to address these challenges by enabling a new computing dynamic through the application of message-driven computation in a global address space context with lightweight synchronization. The work on *HPX* is centered around implementing the concepts as defined by the ParalleX model. *HPX* is currently targeted at conventional machines, such as classical Linux based Beowulf clusters and SMP nodes.

We fully understand that the success of *HPX* (and ParalleX) is very much the result of the work of many people. To see a list of who is contributing see our tables below.

HPX contributors

Acknowledgements

Thanks also to the following people who contributed directly or indirectly to the project through discussions, pull requests, documentation patches, etc.

- Dimitra Karatza for her core contribution on renewing and improving the HPX documentation.
- Srinivas Yadav, for his work on SIMD support in algorithms before and during Google Summer of Code 2021.
- Akhil Nair, for his work on adapting algorithms to C++20 before and during Google Summer of Code 2021.
- Alexander Toktarev, for updating the parallel algorithm customization points to use `tag_fallback_invoke` for the default implementations.
- Brice Goglin, for reporting and helping fix issues related to the integration of hwloc in *HPX*.
- Giannis Gonidelis, for his work on the ranges adaptation during the Google Summer of Code 2020.
- Auriane Reverdell (Swiss National Supercomputing Centre[5661]), for her tireless work on refactoring our CMake setup and modularizing *HPX*.
- Christopher Hinz, for his work on refactoring our CMake setup.
- Weile Wei, for fixing *HPX* builds with CUDA on Summit.
- Severin Strobl, for fixing our CMake setup related to linking and adding new entry points to the *HPX* runtime.
- Rebecca Stobaugh, for her major documentation review and contributions during and after the 2019 Google Season of Documentation.
- Jan Melech, for adding automatic serialization of simple structs.
- Austin McCartney, for adding concept emulation of the Ranges TS bidirectional and random access iterator concepts.
- Marco Diers, reporting and fixing issues related PMIx.
- Maximilian Bremer, for reporting multiple issues and extending the component migration tests.
- Piotr Mikolajczyk, for his improvements and fixes to the set and count algorithms.
- Grant Rostig, for reporting several deficiencies on our web pages.
- Jakub Golinowski, for implementing an *HPX* backend for OpenCV and in the process improving documentation and reporting issues.
- Mikael Simberg (Swiss National Supercomputing Centre[5662]), for his tireless help cleaning up and maintaining *HPX*.
- Tianyi Zhang, for his work on HPXMP.
- Shahrzad Shirzad, for her contributions related to Phylanx.
- Christopher Ogle, for his contributions to the parallel algorithms.
- Surya Priy, for his work with statistic performance counters.
- Anushi Maheshwari, for her work on random number generation.
- Bruno Pitrus, for his work with parallel algorithms.
- Nikunj Gupta, for rewriting the implementation of `hpx_main.hpp` and for his fixes for tests.
- Christopher Taylor, for his interest in *HPX* and the fixes he provided.
- Shoshana Jakobovits, for her work on the resource partitioner.

[5662] https://www.cscs.ch

- Denis Blank, who re-wrote our unwrapped function to accept plain values arbitrary containers, and properly deal with nested futures.
- Ajai V. George, who implemented several of the parallel algorithms.
- Taeguk Kwon, who worked on implementing parallel algorithms as well as adapting the parallel algorithms to the Ranges TS.
- Zach Byerly (Louisiana State University (LSU)[5663]), who in his work developing applications on top of *HPX* opened tickets and contributed to the *HPX* examples.
- Daniel Estermann, for his work porting *HPX* to the Raspberry Pi.
- Alireza Kheirkhahan (Louisiana State University (LSU)[5664]), who built and administered our local cluster as well as his work in distributed IO.
- Abhimanyu Rawat, who worked on stack overflow detection.
- David Pfander, who improved signal handling in *HPX*, provided his optimization expertise, and worked on incorporating the Vc vectorization into *HPX*.
- Denis Demidov, who contributed his insights with VexCL.
- Khalid Hasanov, who contributed changes which allowed to run *HPX* on 64Bit power-pc architectures.
- Zahra Khatami (Louisiana State University (LSU)[5665]), who contributed the prefetching iterators and the persistent auto chunking executor parameters implementation.
- Marcin Copik, who worked on implementing GPU support for C++AMP and HCC. He also worked on implementing a HCC backend for *HPX.Compute*.
- Minh-Khanh Do, who contributed the implementation of several segmented algorithms.
- Bibek Wagle (Louisiana State University (LSU)[5666]), who worked on fixing and analyzing the performance of the *parcel* coalescing plugin in *HPX*.
- Lukas Troska, who reported several problems and contributed various test cases allowing to reproduce the corresponding issues.
- Andreas Schaefer, who worked on integrating his library (LibGeoDecomp[5667]) with *HPX*. He reported various problems and submitted several patches to fix issues allowing for a better integration with LibGeoDecomp[5668].
- Satyaki Upadhyay, who contributed several examples to *HPX*.
- Brandon Cordes, who contributed several improvements to the inspect tool.
- Harris Brakmic, who contributed an extensive build system description for building *HPX* with Visual Studio.
- Parsa Amini (Louisiana State University (LSU)[5669]), who refactored and simplified the implementation of *AGAS* in *HPX* and who works on its implementation and optimization.
- Luis Martinez de Bartolome who implemented a build system extension for *HPX* integrating it with the Conan[5670] C/C++ package manager.
- Vinay C Amatya (Louisiana State University (LSU)[5671]), who contributed to the documentation and provided some of the *HPX* examples.

- Kevin Huck and Nick Chaimov (University of Oregon[5672]), who contributed the integration of APEX (Autonomic Performance Environment for eXascale) with *HPX*.
- Francisco Jose Tapia, who helped with implementing the parallel sort algorithm for *HPX*.
- Patrick Diehl, who worked on implementing CUDA support for our companion library targeting GPGPUs (HPXCL[5673]).
- Eric Lemanissier contributed fixes to allow compilation using the MingW toolchain.
- Nidhi Makhijani who helped cleaning up some enum consistencies in *HPX* and contributed to the resource manager used in the thread scheduling subsystem. She also worked on *HPX* in the context of the Google Summer of Code 2015.
- Larry Xiao, Devang Bacharwar, Marcin Copik, and Konstantin Kronfeldner who worked on *HPX* in the context of the Google Summer of Code program 2015.
- Daniel Bourgeois (Center for Computation and Technology (CCT)[5674]) who contributed to *HPX* the implementation of several parallel algorithms (as proposed by N4313[5675]).
- Anuj Sharma and Christopher Bross (Department of Computer Science 3 - Computer Architecture[5676]), who worked on *HPX* in the context of the Google Summer of Code[5677] program 2014.
- Martin Stumpf (Department of Computer Science 3 - Computer Architecture[5678]), who rebuilt our contiguous testing infrastructure (see the *HPX* Buildbot Website[5679]). Martin is also working on HPXCL[5680] (mainly all work related to OpenCL[5681]) and implementing an *HPX* backend for POCL[5682], a portable computing language solution based on OpenCL[5683].
- Grant Mercer (University of Nevada, Las Vegas[5684]), who helped creating many of the parallel algorithms (as proposed by N4313[5685]).
- Damond Howard (Louisiana State University (LSU)[5686]), who works on HPXCL[5687] (mainly all work related to CUDA[5688]).
- Christoph Junghans (Los Alamos National Lab), who helped making our buildsystem more portable.
- Antoine Tran Tan (Laboratoire de Recherche en Informatique, Paris), who worked on integrating *HPX* as a backend for NT2[5689]. He also contributed an implementation of an API similar to Fortran co-arrays on top of *HPX*.
- John Biddiscombe (Swiss National Supercomputing Centre[5690]), who helped with the BlueGene/Q port of *HPX*, implemented the parallel sort algorithm, and made several other contributions.
- Erik Schnetter (Perimeter Institute for Theoretical Physics), who greatly helped to make *HPX* more robust by submitting a large amount of problem reports, feature requests, and made several direct contributions.

- Mathias Gaunard (Metascale), who contributed several patches to reduce compile time warnings generated while compiling *HPX*.
- Andreas Buhr, who helped with improving our documentation, especially by suggesting some fixes for inconsistencies.
- Patricia Grubel (New Mexico State University[5691]), who contributed the description of the different *HPX* thread scheduler policies and is working on the performance analysis of our thread scheduling subsystem.
- Lars Viklund, whose wit, passion for testing, and love of odd architectures has been an amazing contribution to our team. He has also contributed platform specific patches for FreeBSD and MSVC12.
- Agustin Berge, who contributed patches fixing some very nasty hidden template meta-programming issues. He rewrote large parts of the API elements ensuring strict conformance with the C++ ISO Standard.
- Anton Bikineev for contributing changes to make using `boost::lexical_cast` safer, he also contributed a thread safety fix to the iostreams module. He also contributed a complete rewrite of the serialization infrastructure replacing Boost.Serialization inside *HPX*.
- Pyry Jahkola, who contributed the Mac OS build system and build documentation on how to build *HPX* using Clang and libc++.
- Mario Mulansky, who created an *HPX* backend for his Boost.Odeint library, and who submitted several test cases allowing us to reproduce and fix problems in *HPX*.
- Rekha Raj, who contributed changes to the description of the Windows build instructions.
- Jeremy Kemp how worked on an *HPX* OpenMP backend and added regression tests.
- Alex Nagelberg for his work on implementing a C wrapper API for *HPX*.
- Chen Guo, helvihartmann, Nicholas Pezolano, and John West who added and improved examples in *HPX*.
- Joseph Kleinhenz, Markus Elfring, Kirill Kropivyansky, Alexander Neundorf, Bryant Lam, and Alex Hirsch who improved our CMake.
- Tapasweni Pathak, Praveen Velliengiri, Jean-Loup Tastet, Michael Levine, Aalekh Nigam, HadrienG2, Prayag Verma, lslada, Alex Myczko, and Avyav Kumar who improved the documentation.
- Jayesh Badwaik, J. F. Bastien, Christoph Garth, Christopher Hinz, Brandon Kohn, Mario Lang, Maikel Nadolski, pierrele, hendrx, Dekken, woodmeister123, xaguilar, Andrew Kemp, Dylan Stark, Matthew Anderson, Jeremy Wilke, Jiazheng Yuan, CyberDrudge, david8dixon, Maxwell Reeser, Raffaele Solca, Marco Ippolito, Jules Penuchot, Weile Wei, Severin Strobl, Kor de Jong, albestro, Jeff Trull, Yuri Victorovich, and Gregor Daiß who contributed to the general improvement of *HPX*.
