If you're new to *HPX* you can get started with the [Quick start](#) guide. Don't forget to read the [Terminology](#) section to learn about the most important concepts in *HPX*. The [Examples](#) give you a feel for how it is to write real *HPX* applications and the [Manual](#) contains detailed information about everything from building *HPX* to debugging it. There are links to blog posts and videos about *HPX* in [Additional material](#).

If you can't find what you're looking for in the documentation, please:

- open an issue on [GitHub](#)<sup>1</sup>;
- contact us on [IRC](#), the *HPX* channel on the [C++ Slack](#)<sup>2</sup>, or on our [mailing list](#)<sup>3</sup>; or
- read or ask questions tagged with *HPX* on [StackOverflow](#)<sup>4</sup>.

You can find a comprehensive list of contact options on Support for deploying and using *HPX*<sup>5</sup>.

See [Citing HPX](#) for details on how to cite *HPX* in publications. See [HPX users](#) for a list of institutions and projects using *HPX*.

**CHAPTER  
ONE**

---

## **WHAT IS HPX?**

*HPX* is a C++ Standard Library for Concurrency and Parallelism. It implements all of the corresponding facilities as defined by the C++ Standard. Additionally, in *HPX* we implement functionalities proposed as part of the ongoing C++ standardization process. We also extend the C++ Standard APIs to the distributed case. *HPX* is developed by the STE||AR group (see [People](#)).

The goal of *HPX* is to create a high quality, freely available, open source implementation of a new programming model for conventional systems, such as classic Linux based Beowulf clusters or multi-socket highly parallel SMP nodes. At the same time, we want to have a very modular and well designed runtime system architecture which would allow us to port our implementation onto new computer system architectures. We want to use real-world applications to drive the development of the runtime system, coining out required functionalities and converging onto a stable API which will provide a smooth migration path for developers.

The API exposed by *HPX* is not only modeled after the interfaces defined by the C++11/14/17/20 ISO standard. It also adheres to the programming guidelines used by the Boost collection of C++ libraries. We aim to improve the scalability of today's applications and to expose new levels of parallelism which are necessary to take advantage of the exascale systems of the future.

## WHAT'S SO SPECIAL ABOUT *HPX*?

- HPX exposes a uniform, standards-oriented API for ease of programming parallel and distributed applications.
- It enables programmers to write fully asynchronous code using hundreds of millions of threads.
- HPX provides unified syntax and semantics for local and remote operations.
- HPX makes concurrency manageable with dataflow and future based synchronization.
- It implements a rich set of runtime services supporting a broad range of use cases.
- HPX exposes a uniform, flexible, and extendable performance counter framework which can enable runtime adaptivity
- It is designed to solve problems conventionally considered to be scaling-impaired.
- HPX has been designed and developed for systems of any scale, from hand-held devices to very large scale systems.
- It is the first fully functional implementation of the ParalleX execution model.
- HPX is published under a liberal open-source license and has an open, active, and thriving developer community.

## 2.1 Quick start

The following steps will help you get started with *HPX*.

### 2.1.1 Installing *HPX*

The easiest way to install *HPX* on your system is by choosing one of the steps below:

#### 1. **vcpkg**

You can download and install *HPX* using the `vcpkg`<sup>6</sup> dependency manager:

```
$ vcpkg install hpx
```

#### 2. **Spack**

Another way to install *HPX* is using `Spack`<sup>7</sup>:

```
$ spack install hpx
```

---

<sup>6</sup> <https://github.com/Microsoft/vcpkg>

<sup>7</sup> <https://spack.readthedocs.io/en/latest/>

### 3. Fedora

Installation can be done with Fedora<sup>8</sup> as well:

```
$ dnf install hpx*
```

### 4. Arch Linux

HPX is available in the [Arch User Repository \(AUR\)](#)<sup>9</sup> as `hpx` too.

More information or alternatives regarding the installation can be found in the [Building HPX](#), a detailed guide with thorough explanation of ways to build and use *HPX*.

## 2.1.2 Hello, World!

To get started with this minimal example you need to create a new project directory and a file `CMakeLists.txt` with the contents below in order to build an executable using CMake and *HPX*:

```
cmake_minimum_required(VERSION 3.18)
project(my_hpx_project CXX)
find_package(HPX REQUIRED)
add_executable(my_hpx_program main.cpp)
target_link_libraries(my_hpx_program HPX::hpx HPX::wrap_main HPX::iostreams_component)
```

The next step is to create a `main.cpp` with the contents below:

```
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Then, in your project directory run the following:

```
$ mkdir build && cd build
$ cmake -DCMAKE_PREFIX_PATH=/path/to/hpx/installation ..
$ make all
$ ./my_hpx_program
```

```
$ ./my_hpx_program
Hello World!
```

The program looks almost like a regular C++ hello world with the exception of the two includes and `hpx::cout`.

- When you include `hpx_main.hpp` *HPX* makes sure that `main` actually gets launched on the *HPX* runtime. So while it looks almost the same you can now use futures, `async`, parallel algorithms and more which make use of the *HPX* runtime with lightweight threads.

<sup>8</sup> <https://fedoraproject.org/wiki/DNF>

<sup>9</sup> [https://wiki.archlinux.org/title/Arch\\_User\\_Repository](https://wiki.archlinux.org/title/Arch_User_Repository)

- `hpx::cout` is a replacement for `std::cout` to make sure printing never blocks a lightweight thread. You can read more about `hpx::cout` in [The HPX I/O-streams component](#).

**Note:**

- You will most likely have more than one `main.cpp` file in your project. See the section on [Using HPX with CMake-based projects](#) for more details on how to use `add_hpx_executable`.
- `HPX::wrap_main` is required if you are implicitly using `main()` as the runtime entry point. See [Re-use the main\(\) function as the main HPX entry point](#) for more information.
- `HPX::iostreams_component` is optional for a minimal project but lets us use the *HPX* equivalent of `std::cout`, i.e., the *HPX* [The HPX I/O-streams component](#) functionality in our application.
- You do not have to let *HPX* take over your main function like in the example. See [Starting the HPX runtime](#) for more details on how to initialize and run the *HPX* runtime.

**Caution:** When including `hpx_main.hpp` the user-defined `main` gets renamed and the real `main` function is defined by *HPX*. This means that the user-defined `main` must include a return statement, unlike the real `main`. If you do not include the return statement, you may end up with confusing compile time errors mentioning `user_main` or even runtime errors.

### 2.1.3 Writing task-based applications

So far we haven't done anything that can't be done using the C++ standard library. In this section we will give a short overview of what you can do with *HPX* on a single node. The essence is to avoid global synchronization and break up your application into small, composable tasks whose dependencies control the flow of your application. Remember, however, that *HPX* allows you to write distributed applications similarly to how you would write applications for a single node (see [Why HPX?](#) and [Writing distributed HPX applications](#)).

If you are already familiar with `async` and `futures` from the C++ standard library, the same functionality is available in *HPX*.

The following terminology is essential when talking about task-based C++ programs:

- **lightweight thread:** Essential for good performance with task-based programs. Lightweight refers to smaller stacks and faster context switching compared to OS threads. Smaller overheads allow the program to be broken up into smaller tasks, which in turns helps the runtime fully utilize all processing units.
- **async:** The most basic way of launching tasks asynchronously. Returns a `future<T>`.
- **future<T>:** Represents a value of type `T` that will be ready in the future. The value can be retrieved with `get` (blocking) and one can check if the value is ready with `is_ready` (non-blocking).
- **shared\_future<T>:** Same as `future<T>` but can be copied (similar to `std::unique_ptr` vs `std::shared_ptr`).
- **continuation:** A function that is to be run after a previous task has run (represented by a `future`). `then` is a method of `future<T>` that takes a function to run next. Used to build up dataflow DAGs (directed acyclic graphs). `shared_futures` help you split up nodes in the DAG and functions like `when_all` help you join nodes in the DAG.

The following example is a collection of the most commonly used functionality in *HPX*:

```
#include <hpx/local/algorithm.hpp>
#include <hpx/local/future.hpp>
#include <hpx/local/init.hpp>

#include <iostream>
#include <random>
#include <vector>

void final_task(hpx::future<hpx::tuple<hpx::future<double>, hpx::future<void>>>)
{
    std::cout << "in final_task" << std::endl;
}

int hpx_main()
{
    // A function can be launched asynchronously. The program will not block
    // here until the result is available.
    hpx::future<int> f = hpx::async([]() { return 42; });
    std::cout << "Just launched a task!" << std::endl;

    // Use get to retrieve the value from the future. This will block this task
    // until the future is ready, but the HPX runtime will schedule other tasks
    // if there are tasks available.
    std::cout << "f contains " << f.get() << std::endl;

    // Let's launch another task.
    hpx::future<double> g = hpx::async([]() { return 3.14; });

    // Tasks can be chained using the then method. The continuation takes the
    // future as an argument.
    hpx::future<double> result = g.then([](hpx::future<double>&& gg) {
        // This function will be called once g is ready. gg is g moved
        // into the continuation.
        return gg.get() * 42.0 * 42.0;
    });

    // You can check if a future is ready with the is_ready method.
    std::cout << "Result is ready? " << result.is_ready() << std::endl;

    // You can launch other work in the meantime. Let's sort a vector.
    std::vector<int> v(1000000);

    // We fill the vector synchronously and sequentially.
    hpx::generate(hpx::execution::seq, std::begin(v), std::end(v), &std::rand);

    // We can launch the sort in parallel and asynchronously.
    hpx::future<void> done_sorting =
        hpx::sort(hpx::execution::par(           // In parallel.
            hpx::execution::task),             // Asynchronously.
            std::begin(v), std::end(v));

    // We launch the final task when the vector has been sorted and result is
    // ready using when_all.
```

(continues on next page)

(continued from previous page)

```

auto all = hpx::when_all(result, done_sorting).then(&final_task);

// We can wait for all to be ready.
all.wait();

// all must be ready at this point because we waited for it to be ready.
std::cout << (all.is_ready() ? "all is ready!" : "all is not ready...")
    << std::endl;

return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}

```

Try copying the contents to your `main.cpp` file and look at the output. It can be a good idea to go through the program step by step with a debugger. You can also try changing the types or adding new arguments to functions to make sure you can get the types to match. The type of the `then` method can be especially tricky to get right (the continuation needs to take the future as an argument).

---

**Note:** *HPX* programs accept command line arguments. The most important one is `--hpx:threads=N` to set the number of OS threads used by *HPX*. *HPX* uses one thread per core by default. Play around with the example above and see what difference the number of threads makes on the `sort` function. See [Launching and configuring HPX applications](#) for more details on how and what options you can pass to *HPX*.

---

**Tip:** The example above used the construction `hpx::when_all(...).then(...)`. For convenience and performance it is a good idea to replace uses of `hpx::when_all(...).then(...)` with `dataflow`. See [Dataflow](#) for more details on `dataflow`.

---

**Tip:** If possible, try to use the provided parallel algorithms instead of writing your own implementation. This can save you time and the resulting program is often faster.

---

## 2.1.4 Next steps

If you haven't done so already, reading the [Terminology](#) section will help you get familiar with the terms used in *HPX*.

The [Examples](#) section contains small, self-contained walkthroughs of example *HPX* programs. The [Local to remote](#) example is a thorough, realistic example starting from a single node implementation and going stepwise to a distributed implementation.

The [Manual](#) contains detailed information on writing, building and running *HPX* applications.

## 2.2 Examples

The following sections analyze some examples to help you get familiar with the *HPX* style of programming. We start off with simple examples that utilize basic *HPX* elements and then begin to expose the reader to the more complex and powerful *HPX* concepts.

### 2.2.1 Asynchronous execution

The Fibonacci sequence is a sequence of numbers starting with 0 and 1 where every subsequent number is the sum of the previous two numbers. In this example, we will use *HPX* to calculate the value of the n-th element of the Fibonacci sequence. In order to compute this problem in parallel, we will use a facility known as a future.

As shown in the Fig. 2.1 below, a future encapsulates a delayed computation. It acts as a proxy for a result initially not known, most of the time because the computation of the result has not completed yet. The future synchronizes the access of this value by optionally suspending any *HPX*-threads requesting the result until the value is available. When a future is created, it spawns a new *HPX*-thread (either remotely with a *parcel* or locally by placing it into the thread queue) which, when run, will execute the function associated with the future. The arguments of the function are bound when the future is created.

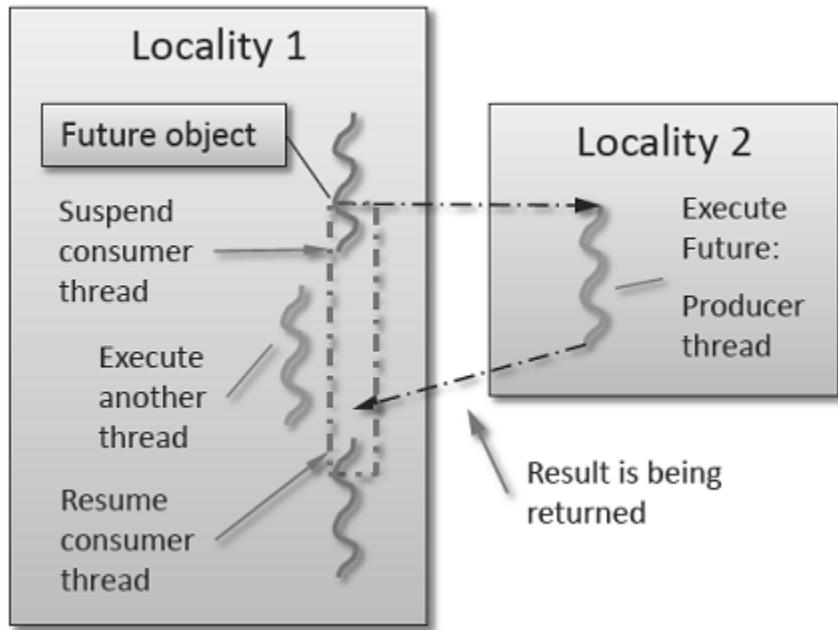

Fig. 2.1: Schematic of a future execution.

Once the function has finished executing, a write operation is performed on the future. The write operation marks the future as completed, and optionally stores data returned by the function. When the result of the delayed computation is needed, a read operation is performed on the future. If the future's function hasn't completed when a read operation is performed on it, the reader *HPX*-thread is suspended until the future is ready. The future facility allows *HPX* to schedule work early in a program so that when the function value is needed it will already be calculated and available. We use this property in our Fibonacci example below to enable its parallel execution.

## Setup

The source code for this example can be found here: `fibonacci_local.cpp`.

To compile this program, go to your *HPX* build directory (see [Building HPX](#) for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.fibonacci_local
```

To run the program type:

```
$ ./bin/fibonacci_local
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.002430 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
$ ./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.062854 [s]
```

## Walkthrough

Now that you have compiled and run the code, let's look at how the code works. Since this code is written in C++, we will begin with the `main()` function. Here you can see that in *HPX*, `main()` is only used to initialize the runtime system. It is important to note that application-specific command line options are defined here. *HPX* uses [Boost.Program Options](#)<sup>10</sup> for command line processing. You can see that our programs `--n-value` option is set by calling the `add_options()` method on an instance of `hpx::program_options::options_description`. The default value of the variable is set to 10. This is why when we ran the program for the first time without using the `--n-value` option the program returned the 10th value of the Fibonacci sequence. The constructor argument of the description is the text that appears when a user uses the `--hpx:help` option to see what command line options are available. `HPX_APPLICATION_STRING` is a macro that expands to a string constant containing the name of the *HPX* application currently being compiled.

In *HPX* `main()` is used to initialize the runtime system and pass the command line arguments to the program. If you wish to add command line options to your program you would add them here using the instance of the Boost class `options_description`, and invoking the public member function `.add_options()` (see [Boost Documentation](#)<sup>11</sup> for more details). `hpx::init` calls `hpx_main()` after setting up *HPX*, which is where the logic of our program is encoded.

```
int main(int argc, char* argv[])
{
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: " HPX_APPLICATION_STRING " [options]");
```

(continues on next page)

<sup>10</sup> [https://www.boost.org/doc/html/program\\_options.html](https://www.boost.org/doc/html/program_options.html)

<sup>11</sup> <https://www.boost.org/doc/>

(continued from previous page)

```

desc_commandline.add_options()("n-value",
    hpx::program_options::value<std::uint64_t>().default_value(10),
    "n value for the Fibonacci function");

// Initialize and run HPX
hpx::local::init_params init_args;
init_args.desc_cmdline = desc_commandline;

return hpx::local::init(hpx_main, argc, argv, init_args);
}

```

The `hpx::init` function in `main()` starts the runtime system, and invokes `hpx_main()` as the first *HPX*-thread. Below we can see that the basic program is simple. The command line option `--n-value` is read in, a timer (`hpx::chrono::high_resolution_timer`) is set up to record the time it takes to do the computation, the `fibonacci` function is invoked synchronously, and the answer is printed out.

```

int hpx_main(hpx::program_options::variables_map& vm)
{
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    {
        // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;

        std::uint64_t r = fibonacci(n);

        char const* fmt = "fibonacci({1}) == {2}\nelapsed time: {3} [s]\n";
        hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
    }

    return hpx::local::finalize();    // Handles HPX shutdown
}

```

The `fibonacci` function itself is synchronous as the work done inside is asynchronous. To understand what is happening we have to look inside the `fibonacci` function:

```

std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    hpx::future<std::uint64_t> n1 = hpx::async(fibonacci, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fibonacci, n - 2);

    return n1.get() +
        n2.get();    // wait for the Futures to return their values
}

```

This block of code looks similar to regular C++ code. First, `if (n < 2)`, meaning n is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If n is larger than 1 we spawn two new tasks whose results are contained in `n1` and `n2`. This is done using `hpx::async` which takes as arguments a function (function pointer, object or lambda) and the arguments to the function. Instead of returning a `std::uint64_t` like `fibonacci` does, `hpx::async` returns a future of a `std::uint64_t`, i.e. `hpx::future<std::uint64_t>`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. After we've created the futures, we wait for both of them to finish computing, we add them together, and return that value as our result. We get the values from the futures using the `get` method. The recursive call tree will continue until n is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the n-th value of the Fibonacci sequence.

Note that calling `get` potentially blocks the calling *HPX*-thread, and lets other *HPX*-threads run in the meantime. There are, however, more efficient ways of doing this. `examples/quickstart/fibonacci_futures.cpp` contains many more variations of locally computing the Fibonacci numbers, where each method makes different tradeoffs in where asynchrony and parallelism is applied. To get started, however, the method above is sufficient and optimizations can be applied once you are more familiar with *HPX*. The example [Dataflow](#) presents dataflow, which is a way to more efficiently chain together multiple tasks.

## 2.2.2 Parallel algorithms

This program will perform a matrix multiplication in parallel. The output will look something like this:

```
Matrix A is :
4 9 6
1 9 8
```

```
Matrix B is :
4 9
6 1
9 8
```

```
Resultant Matrix is :
124 93
111 127
```

### Setup

The source code for this example can be found here: `matrix_multiplication.cpp`.

To compile this program, go to your *HPX* build directory (see [Building HPX](#) for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.matrix_multiplication
```

To run the program type:

```
$ ./bin/matrix_multiplication
```

or:

```
$ ./bin/matrix_multiplication --n 2 --m 3 --k 2 --s 100 --l 0 --u 10
```

where the first matrix is  $n \times m$  and the second  $m \times k$ , s is the seed for creating the random values of the matrices and the range of these values is  $[l, u]$

This should print:

```
Matrix A is :  
4 9 6  
1 9 8  
  
Matrix B is :  
4 9  
6 1  
9 8  
  
Resultant Matrix is :  
124 93  
111 127
```

Notice that the numbers may be different because of the random initialization of the matrices.

## Walkthrough

Now that you have compiled and run the code, let's look at how the code works.

First, `main()` is used to initialize the runtime system and pass the command line arguments to the program. `hpx::init` calls `hpx_main()` after setting up HPX, which is where our program is implemented.

```
int main(int argc, char* argv[])
{
    using namespace hpx::program_options;
    options_description cmdline("usage: " HPX_APPLICATION_STRING " [options]");
    // clang-format off
    cmdline.add_options()
        ("n",
         hpx::program_options::value<std::size_t>()>default_value(2),
         "Number of rows of first matrix")
        ("m",
         hpx::program_options::value<std::size_t>()>default_value(3),
         "Number of columns of first matrix (equal to the number of rows of "
         "second matrix")
        ("k",
         hpx::program_options::value<std::size_t>()>default_value(2),
         "Number of columns of second matrix")
        ("seed,s",
         hpx::program_options::value<unsigned int>(),
         "The random number generator seed to use for this run")
        ("l",
         hpx::program_options::value<int>()>default_value(0),
         "Lower limit of range of values")
        ("u",
         hpx::program_options::value<int>()>default_value(10),
         "Upper limit of range of values");
    // clang-format on
    hpx::local::init_params init_args;
    init_args.desc_cmdline = cmdline;
```

(continues on next page)

(continued from previous page)

```

    return hpx::local::init(hpx_main, argc, argv, init_args);
}

```

Proceeding to the `hpx_main()` function, we can see that matrix multiplication can be done very easily.

```

int hpx_main(hpx::program_options::variables_map& vm)
{
    using element_type = int;

    // Define matrix sizes
    std::size_t rowsA = vm["n"].as<std::size_t>();
    std::size_t colsA = vm["m"].as<std::size_t>();
    std::size_t rowsB = colsA;
    std::size_t colsB = vm["k"].as<std::size_t>();
    std::size_t rowsR = rowsA;
    std::size_t colsR = colsB;

    // Initialize matrices A and B
    std::vector<int> A(rowsA * colsA);
    std::vector<int> B(rowsB * colsB);
    std::vector<int> R(rowsR * colsR);

    // Define seed
    unsigned int seed = std::random_device{}();
    if (vm.count("seed"))
        seed = vm["seed"].as<unsigned int>();

    gen.seed(seed);
    std::cout << "using seed: " << seed << std::endl;

    // Define range of values
    int lower = vm["l"].as<int>();
    int upper = vm["u"].as<int>();

    // Matrices have random values in the range [lower, upper]
    std::uniform_int_distribution<element_type> dis(lower, upper);
    auto generator = std::bind(dis, gen);
    hpx::ranges::generate(A, generator);
    hpx::ranges::generate(B, generator);

    // Perform matrix multiplication
    hpx::experimental::for_loop(hpx::execution::par, 0, rowsA, [&](auto i) {
        hpx::experimental::for_loop(0, colsB, [&](auto j) {
            R[i * colsR + j] = 0;
            hpx::experimental::for_loop(0, rowsB, [&](auto k) {
                R[i * colsR + j] += A[i * colsA + k] * B[k * colsB + j];
            });
        });
    });

    // Print all 3 matrices
    print_matrix(A, rowsA, colsA, "A");

```

(continues on next page)

(continued from previous page)

```

print_matrix(B, rowsB, colsB, "B");
print_matrix(R, rowsR, colsR, "R");

return hpx::local::finalize();
}

```

First, the dimensions of the matrices are defined. If they were not given as command-line arguments, their default values are  $2 \times 3$  for the first matrix and  $3 \times 2$  for the second. We use standard vectors to define the matrices to be multiplied as well as the resultant matrix.

To give some random initial values to our matrices, we use `std::uniform_int_distribution`<sup>12</sup>. Then, `std::bind()` is used along with `hpx::ranges::generate()` to yield two matrices A and B, which contain values in the range of [0, 10] or in the range defined by the user at the command-line arguments. The seed to generate the values can also be defined by the user.

The next step is to perform the matrix multiplication in parallel. This can be done by just using an `hpx::experimental::for_loop` combined with a parallel execution policy `hpx::execution::par` as the outer loop of the multiplication. Note that the execution of `hpx::experimental::for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Finally, the matrices A, B that are multiplied as well as the resultant matrix R are printed using the following function.

```

void print_matrix(
    std::vector<int> M, std::size_t rows, std::size_t cols, const char* message)
{
    std::cout << "\nMatrix " << message << " is:" << std::endl;
    for (std::size_t i = 0; i < rows; i++)
    {
        for (std::size_t j = 0; j < cols; j++)
            std::cout << M[i * cols + j] << " ";
        std::cout << "\n";
    }
}

```

## 2.2.3 Asynchronous execution with actions

This example extends the [previous example](#) by introducing *actions*: functions that can be run remotely. In this example, however, we will still only run the action locally. The mechanism to execute *actions* stays the same: `hpx::async`. Later examples will demonstrate running actions on remote *localities* (e.g. [Remote execution with actions](#)).

### Setup

The source code for this example can be found here: `fibonacci.cpp`.

To compile this program, go to your *HPX* build directory (see [Building HPX](#) for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.fibonacci
```

To run the program type:

<sup>12</sup> [https://en.cppreference.com/w/cpp/numeric/random/uniform\\_int\\_distribution](https://en.cppreference.com/w/cpp/numeric/random/uniform_int_distribution)

```
$ ./bin/fibonacci
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.00186288 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
$ ./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.233827 [s]
```

## Walkthrough

The code needed to initialize the *HPX* runtime is the same as in the *previous example*:

```
int main(int argc, char* argv[])
{
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: " HPX_APPLICATION_STRING " [options]");

    desc_commandline.add_options()("n-value",
        hpx::program_options::value<std::uint64_t>()>default_value(10),
        "n value for the Fibonacci function");

    // Initialize and run HPX
    hpx::init_params init_args;
    init_args.desc_cmdline = desc_commandline;

    return hpx::init(argc, argv, init_args);
}
```

The `hpx::init` function in `main()` starts the runtime system, and invokes `hpx_main()` as the first *HPX*-thread. The command line option `--n-value` is read in, a timer (`hpx::chrono::high_resolution_timer`) is set up to record the time it takes to do the computation, the `fibonacci` *action* is invoked synchronously, and the answer is printed out.

```
int hpx_main(hpx::program_options::variables_map& vm)
{
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    {
        // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;
```

(continues on next page)

(continued from previous page)

```
// Wait for fib() to return the value
fibonacci_action fib;
std::uint64_t r = fib(hpx::find_here(), n);

char const* fmt = "fibonacci({1}) == {2}\nelapsed time: {3} [s]\n";
hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
}

return hpx::finalize(); // Handles HPX shutdown
}
```

Upon a closer look we see that we've created a `std::uint64_t` to store the result of invoking our `fibonacci_action` `fib`. This `action` will launch synchronously (as the work done inside of the `action` will be asynchronous itself) and return the result of the Fibonacci sequence. But wait, what is an `action`? And what is this `fibonacci_action`? For starters, an `action` is a wrapper for a function. By wrapping functions, *HPX* can send packets of work to different processing units. These vehicles allow users to calculate work now, later, or on certain nodes. The first argument to our `action` is the location where the `action` should be run. In this case, we just want to run the `action` on the machine that we are currently on, so we use `hpx::find_here`. To further understand this we turn to the code to find where `fibonacci_action` was defined:

```
// forward declaration of the Fibonacci function
std::uint64_t fibonacci(std::uint64_t n);

// This is to generate the required boilerplate we need for the remote
// invocation to work.
HPX_PLAIN_ACTION(fibonacci, fibonacci_action)
```

A plain `action` is the most basic form of `action`. Plain `actions` wrap simple global functions which are not associated with any particular object (we will discuss other types of `actions` in [Components and actions](#)). In this block of code the function `fibonacci()` is declared. After the declaration, the function is wrapped in an `action` in the declaration `HPX_PLAIN_ACTION`. This function takes two arguments: the name of the function that is to be wrapped and the name of the `action` that you are creating.

This picture should now start making sense. The function `fibonacci()` is wrapped in an `action` `fibonacci_action`, which was run synchronously but created asynchronous work, then returns a `std::uint64_t` representing the result of the function `fibonacci()`. Now, let's look at the function `fibonacci()`:

```
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // We restrict ourselves to execute the Fibonacci function locally.
    hpx::id_type const locality_id = hpx::find_here();

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    fibonacci_action fib;
    hpx::future<std::uint64_t> n1 = hpx::async(fib, locality_id, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fib, locality_id, n - 2);
```

(continues on next page)

(continued from previous page)

```

return n1.get() +
    n2.get();    // wait for the Futures to return their values
}

```

This block of code is much more straightforward and should look familiar from the [previous example](#). First, `if (n < 2)`, meaning `n` is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If `n` is larger than 1 we spawn two tasks using `hpx::async`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. As previously we wait for both futures to finish computing, get the results, add them together, and return that value as our result. The recursive call tree will continue until `n` is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the `n`-th value of the Fibonacci sequence.

## 2.2.4 Remote execution with actions

This program will print out a hello world message on every OS-thread on every *locality*. The output will look something like this:

```

hello world from OS-thread 1 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 0 on locality 1

```

### Setup

The source code for this example can be found here: `hello_world_distributed.cpp`.

To compile this program, go to your *HPX* build directory (see [Building HPX](#) for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.hello_world_distributed
```

To run the program type:

```
$ ./bin/hello_world_distributed
```

This should print:

```
hello world from OS-thread 0 on locality 0
```

To use more OS-threads use the command line option `--hpx:threads` and type the number of threads that you wish to use. For example, typing:

```
$ ./bin/hello_world_distributed --hpx:threads 2
```

will yield:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
```

Notice how the ordering of the two print statements will change with subsequent runs. To run this program on multiple localities please see the section [How to use HPX applications with PBS](#).

## Walkthrough

Now that you have compiled and run the code, let's look at how the code works, beginning with `main()`:

```
// Here is the main entry point. By using the include 'hpx/hpx_main.hpp' HPX
// will invoke the plain old C-main() as its first HPX thread.
int main()
{
    // Get a list of all available localities.
    std::vector<hpx::id_type> localities = hpx::find_all_localities();

    // Reserve storage space for futures, one for each locality.
    std::vector<hpx::future<void>> futures;
    futures.reserve(localities.size());

    for (hpx::id_type const& node : localities)
    {
        // Asynchronously start a new task. The task is encapsulated in a
        // future, which we can query to determine if the task has
        // completed.
        typedef hello_world_foreman_action action_type;
        futures.push_back(hpx::async<action_type>(node));
    }

    // The non-callback version of hpx::wait_all takes a single parameter,
    // a vector of futures to wait on. hpx::wait_all only returns when
    // all of the futures have finished.
    hpx::wait_all(futures);
    return 0;
}
```

In this excerpt of the code we again see the use of futures. This time the futures are stored in a vector so that they can easily be accessed. `hpx::wait_all` is a family of functions that wait on for an `std::vector<...>` of futures to become ready. In this piece of code, we are using the synchronous version of `hpx::wait_all`, which takes one argument (the `std::vector<...>` of futures to wait on). This function will not return until all the futures in the vector have been executed.

In [Asynchronous execution with actions](#) we used `hpx::find_here` to specify the target of our actions. Here, we instead use `hpx::find_all_localities`, which returns an `std::vector<...>` containing the identifiers of all the machines in the system, including the one that we are on.

As in [Asynchronous execution with actions](#) our futures are set using `hpx::async<...>`. The `hello_world_foreman_action` is declared here:

```
// Define the boilerplate code necessary for the function 'hello_world_foreman'
// to be invoked as an HPX action.
HPX_PLAIN_ACTION(hello_world_foreman, hello_world_foreman_action)
```

Another way of thinking about this wrapping technique is as follows: functions (the work to be done) are wrapped in actions, and actions can be executed locally or remotely (e.g. on another machine participating in the computation).

Now it is time to look at the `hello_world_foreman()` function which was wrapped in the action above:

```
void hello_world_foreman()
{
```

(continues on next page)

(continued from previous page)

```

// Get the number of worker OS-threads in use by this locality.
std::size_t const os_threads = hpx::get_os_thread_count();

// Populate a set with the OS-thread numbers of all OS-threads on this
// locality. When the hello world message has been printed on a particular
// OS-thread, we will remove it from the set.
std::set<std::size_t> attendance;
for (std::size_t os_thread = 0; os_thread < os_threads; ++os_thread)
    attendance.insert(os_thread);

// As long as there are still elements in the set, we must keep scheduling
// HPX-threads. Because HPX features work-stealing task schedulers, we have
// no way of enforcing which worker OS-thread will actually execute
// each HPX-thread.
while (!attendance.empty())
{
    // Each iteration, we create a task for each element in the set of
    // OS-threads that have not said "Hello world". Each of these tasks
    // is encapsulated in a future.
    std::vector<hpx::future<std::size_t>> futures;
    futures.reserve(attendance.size());

    for (std::size_t worker : attendance)
    {
        // Asynchronously start a new task. The task is encapsulated in a
        // future that we can query to determine if the task has completed.
        //
        // We give the task a hint to run on a particular worker thread
        // (core) and suggest binding the scheduled thread to the given
        // core, but no guarantees are given by the scheduler that the task
        // will actually run on that worker thread. It will however try as
        // hard as possible to place the new task on the given worker
        // thread.
        hpx::execution::parallel_executor exec(
            hpx::threads::thread_priority::bound);

        hpx::threads::thread_schedule_hint hint(
            hpx::threads::thread_schedule_hint_mode::thread,
            static_cast<std::int16_t>(worker));

        futures.push_back(
            hpx::async(hpx::execution::experimental::with_hint(exec, hint),
                      hello_world_worker, worker));
    }

    // Wait for all of the futures to finish. The callback version of the
    // hpx::wait_each function takes two arguments: a vector of futures,
    // and a binary callback. The callback takes two arguments; the first
    // is the index of the future in the vector, and the second is the
    // return value of the future. hpx::wait_each doesn't return until
    // all the futures in the vector have returned.
    hpx::spinlock mtx;
}

```

(continues on next page)

(continued from previous page)

```

    hpx::wait_each(hpx::unwrapping([&](std::size_t t) {
        if (std::size_t(-1) != t)
        {
            std::lock_guard<hpx::spinlock> lk(mtx);
            attendance.erase(t);
        }
    }), futures);
}
}

```

Now, before we discuss `hello_world_foreman()`, let's talk about the `hpx::wait_each` function. The version of `hpx::wait_each` invokes a callback function provided by the user, supplying the callback function with the result of the future.

In `hello_world_foreman()`, an `std::set` called `attendance` keeps track of which OS-threads have printed out the hello world message. When the OS-thread prints out the statement, the future is marked as ready, and `hpx::wait_each` in `hello_world_foreman()`. If it is not executing on the correct OS-thread, it returns a value of -1, which causes `hello_world_foreman()` to leave the OS-thread id in `attendance`.

```

std::size_t hello_world_worker(std::size_t desired)
{
    // Returns the OS-thread number of the worker that is running this
    // HPX-thread.
    std::size_t current = hpx::get_worker_thread_num();
    if (current == desired)
    {
        // The HPX-thread has been run on the desired OS-thread.
        char const* msg = "hello world from OS-thread {1} on locality {2}\n";

        hpx::util::format_to(hpx::cout, msg, desired, hpx::get_locality_id())
            << std::flush;

        return desired;
    }

    // This HPX-thread has been run by the wrong OS-thread, make the foreman
    // try again by rescheduling it.
    return std::size_t(-1);
}

```

Because *HPX* features work stealing task schedulers, there is no way to guarantee that an action will be scheduled on a particular OS-thread. This is why we must use a guess-and-check approach.

## 2.2.5 Components and actions

The accumulator example demonstrates the use of components. Components are C++ classes that expose methods as a type of *HPX* action. These actions are called component actions.

Components are globally named, meaning that a component action can be called remotely (e.g., from another machine). There are two accumulator examples in *HPX*.

In the *Asynchronous execution with actions* and the *Remote execution with actions*, we introduced plain actions, which wrapped global functions. The target of a plain action is an identifier which refers to a particular machine involved in the computation. For plain actions, the target is the machine where the action will be executed.

Component actions, however, do not target machines. Instead, they target component instances. The instance may live on the machine that we've invoked the component action from, or it may live on another machine.

The component in this example exposes three different functions:

- `reset()` - Resets the accumulator value to 0.
- `add(arg)` - Adds `arg` to the accumulators value.
- `query()` - Queries the value of the accumulator.

This example creates an instance of the accumulator, and then allows the user to enter commands at a prompt, which subsequently invoke actions on the accumulator instance.

### Setup

The source code for this example can be found here: `accumulator_client.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.accumulators.accumulator
```

To run the program type:

```
$ ./bin/accumulator_client
```

Once the program starts running, it will print the following prompt and then wait for input. An example session is given below:

```
commands: reset, add [amount], query, help, quit
> add 5
> add 10
> query
15
> add 2
> query
17
> reset
> add 1
> query
1
> quit
```

## Walkthrough

Now, let's take a look at the source code of the accumulator example. This example consists of two parts: an *HPX* component library (a library that exposes an *HPX* component) and a client application which uses the library. This walkthrough will cover the *HPX* component library. The code for the client application can be found here: `accumulator_client.cpp`.

An *HPX* component is represented by two C++ classes:

- **A server class** - The implementation of the component's functionality.
- **A client class** - A high-level interface that acts as a proxy for an instance of the component.

Typically, these two classes both have the same name, but the server class usually lives in different sub-namespaces (`server`). For example, the full names of the two classes in `accumulator` are:

- `examples::server::accumulator` (server class)
- `examples::accumulator` (client class)

### The server class

The following code is from: `accumulator.hpp`.

All *HPX* component server classes must inherit publicly from the *HPX* component base class: `hpx::components::component_base`

The `accumulator` component inherits from `hpx::components::locking_hook`. This allows the runtime system to ensure that all action invocations are serialized. That means that the system ensures that no two actions are invoked at the same time on a given component instance. This makes the component thread safe and no additional locking has to be implemented by the user. Moreover, an `accumulator` component is a component because it also inherits from `hpx::components::component_base` (the template argument passed to `locking_hook` is used as its base class). The following snippet shows the corresponding code:

```
class accumulator
: public hpx::components::locking_hook<
    hpx::components::component_base<accumulator>>
```

Our `accumulator` class will need a data member to store its value in, so let's declare a data member:

```
argument_type value_;
```

The constructor for this class simply initializes `value_` to 0:

```
accumulator()
: value_(0)
{}
```

Next, let's look at the three methods of this component that we will be exposing as component actions:

Here are the action types. These types wrap the methods we're exposing. The wrapping technique is very similar to the one used in the [Asynchronous execution with actions](#) and the [Remote execution with actions](#):

```
HPX_DEFINE_COMPONENT_ACTION(accumulator, reset)
HPX_DEFINE_COMPONENT_ACTION(accumulator, add)
HPX_DEFINE_COMPONENT_ACTION(accumulator, query)
```

The last piece of code in the server class header is the declaration of the action type registration code:

```
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::reset_action, accumulator_reset_action)

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::add_action, accumulator_add_action)

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::query_action, accumulator_query_action)
```

---

**Note:** The code above must be placed in the global namespace.

---

The rest of the registration code is in `accumulator.cpp`

```
////////////////////////////////////////////////////////////////
// Add factory registration functionality.
HPX_REGISTER_COMPONENT_MODULE()

////////////////////////////////////////////////////////////////
typedef hpx::components::component<examples::server::accumulator>
    accumulator_type;

HPX_REGISTER_COMPONENT(accumulator_type, accumulator)

////////////////////////////////////////////////////////////////
// Serialization support for accumulator actions.
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::reset_action, accumulator_reset_action)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::add_action, accumulator_add_action)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::query_action, accumulator_query_action)
```

---

**Note:** The code above must be placed in the global namespace.

---

## The client class

The following code is from `accumulator.hpp`.

The client class is the primary interface to a component instance. Client classes are used to create components:

```
// Create a component on this locality.
examples::accumulator c = hpx::new_<examples::accumulator>(hpx::find_here());
```

and to invoke component actions:

```
c.add(hpx::launch::apply, 4);
```

Clients, like servers, need to inherit from a base class, this time, `hpx::components::client_base`:

```
class accumulator
: public hpx::components::client_base<accumulator, server::accumulator>
```

For readability, we typedef the base class like so:

```
typedef hpx::components::client_base<accumulator, server::accumulator>
base_type;
```

Here are examples of how to expose actions through a client class:

There are a few different ways of invoking actions:

- **Non-blocking:** For actions that don't have return types, or when we do not care about the result of an action, we can invoke the action using fire-and-forget semantics. This means that once we have asked *HPX* to compute the action, we forget about it completely and continue with our computation. We use `hpx::apply` to invoke an action in a non-blocking fashion.

```
void reset(hpx::launch::apply_policy)
{
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::reset_action action_type;
    hpx::apply<action_type>(this->get_id());
}
```

- **Asynchronous:** Futures, as demonstrated in [Asynchronous execution](#), [Asynchronous execution with actions](#), and the [Remote execution with actions](#), enable asynchronous action invocation. Here's an example from the accumulator client class:

```
hpx::future<argument_type> query(hpx::launch::async_policy)
{
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::query_action action_type;
    return hpx::async<action_type>(hpx::launch::async, this->get_id());
}
```

- **Synchronous:** To invoke an action in a fully synchronous manner, we can simply call `hpx::async().get()` (i.e., create a future and immediately wait on it to be ready). Here's an example from the accumulator client class:

```
void add(argument_type arg)
{
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::add_action action_type;
    action_type()(this->get_id(), arg);
}
```

Note that `this->get_id()` references a data member of the `hpx::components::client_base` base class which identifies the server accumulator instance.

`hpx::naming::id_type` is a type which represents a global identifier in *HPX*. This type specifies the target of an action. This is the type that is returned by `hpx::find_here` in which case it represents the *locality* the code is running on.

## 2.2.6 Dataflow

HPX provides its users with several different tools to simply express parallel concepts. One of these tools is a *local control object (LCO)* called dataflow. An *LCO* is a type of component that can spawn a new thread when triggered. They are also distinguished from other components by a standard interface that allow users to understand and use them easily. A Dataflow, being an *LCO*, is triggered when the values it depends on become available. For instance, if you have a calculation X that depends on the results of three other calculations, you could set up a dataflow that would begin the calculation X as soon as the other three calculations have returned their values. Dataflows are set up to depend on other dataflows. It is this property that makes dataflow a powerful parallelization tool. If you understand the dependencies of your calculation, you can devise a simple algorithm that sets up a dependency tree to be executed. In this example, we calculate compound interest. To calculate compound interest, one must calculate the interest made in each compound period, and then add that interest back to the principal before calculating the interest made in the next period. A practical person would, of course, use the formula for compound interest:

$$F = P(1 + i)^n$$

where  $F$  is the future value,  $P$  is the principal value,  $i$  is the interest rate, and  $n$  is the number of compound periods. However, for the sake of this example, we have chosen to manually calculate the future value by iterating:

$$I = Pi$$

and

$$P = P + I$$

### Setup

The source code for this example can be found here: `interest_calculator.cpp`.

To compile this program, go to your HPX build directory (see [Building HPX](#) for information on configuring and building HPX) and enter:

```
$ make examples.quickstart.interest_calculator
```

To run the program type:

```
$ ./bin/interest_calculator --principal 100 --rate 5 --cp 6 --time 36
Final amount: 134.01
Amount made: 34.0096
```

### Walkthrough

Let us begin with main. Here we can see that we again are using Boost.Program Options to set our command line variables (see [Asynchronous execution with actions](#) for more details). These options set the principal, rate, compound period, and time. It is important to note that the units of time for cp and time must be the same.

```
int main(int argc, char** argv)
{
    options_description cmdline("Usage: " HPX_APPLICATION_STRING " [options]");
    cmdline.add_options()("principal", value<double>()>default_value(1000),
                         "The principal [$]")
        ("rate", value<double>()>default_value(7),
```

(continues on next page)

(continued from previous page)

```

"The interest rate [%]"("cp", value<int>()>default_value(12),
"The compound period [months]"("time",
value<int>()>default_value(12 * 30),
"The time money is invested [months]");

hpx::init_params init_args;
init_args.desc_cmdline = cmdline;

return hpx::init(argc, argv, init_args);
}

```

Next we look at hpx\_main.

```

int hpx_main(variables_map& vm)
{
{
    using hpx::dataflow;
    using hpx::make_ready_future;
    using hpx::shared_future;
    using hpx::unwrapping;
    hpx::id_type here = hpx::find_here();

    double init_principal =
        vm["principal"].as<double>();           //Initial principal
    double init_rate = vm["rate"].as<double>();   //Interest rate
    int cp = vm["cp"].as<int>();      //Length of a compound period
    int t = vm["time"].as<int>();      //Length of time money is invested

    init_rate /= 100;      //Rate is a % and must be converted
    t /= cp;      //Determine how many times to iterate interest calculation:
                  //How many full compound periods can fit in the time invested

    // In non-dataflow terms the implemented algorithm would look like:
    //
    // int t = 5;      // number of time periods to use
    // double principal = init_principal;
    // double rate = init_rate;
    //
    // for (int i = 0; i < t; ++i)
    // {
    //     double interest = calc(principal, rate);
    //     principal = add(principal, interest);
    // }
    //
    // Please note the similarity with the code below!

    shared_future<double> principal = make_ready_future(init_principal);
    shared_future<double> rate = make_ready_future(init_rate);

    for (int i = 0; i < t; ++i)
    {
        shared_future<double> interest =

```

(continues on next page)

(continued from previous page)

```

        dataflow(unwrapping(calc), principal, rate);
        principal = dataflow(unwrapping(add), principal, interest);
    }

    // wait for the dataflow execution graph to be finished calculating our
// overall interest
    double result = principal.get();

    std::cout << "Final amount: " << result << std::endl;
    std::cout << "Amount made: " << result - init_principal << std::endl;
}

return hpx::finalize();
}

```

Here we find our command line variables read in, the rate is converted from a percent to a decimal, the number of calculation iterations is determined, and then our shared\_futures are set up. Notice that we first place our principal and rate into shares futures by passing the variables `init_principal` and `init_rate` using `hpx::make_ready_future`.

In this way `hpx::shared_future<double>` `principal` and `rate` will be initialized to `init_principal` and `init_rate` when `hpx::make_ready_future<double>` returns a future containing those initial values. These shared futures then enter the for loop and are passed to `interest`. Next `principal` and `interest` are passed to the reassignment of `principal` using a `hpx::dataflow`. A dataflow will first wait for its arguments to be ready before launching any callbacks, so `add` in this case will not begin until both `principal` and `interest` are ready. This loop continues for each compound period that must be calculated. To see how `interest` and `principal` are calculated in the loop, let us look at `calc_action` and `add_action`:

```

// Calculate interest for one period
double calc(double principal, double rate)
{
    return principal * rate;
}

///////////////////////////////
// Add the amount made to the principal
double add(double principal, double interest)
{
    return principal + interest;
}

```

After the shared future dependencies have been defined in `hpx_main`, we see the following statement:

```
double result = principal.get();
```

This statement calls `hpx::future::get` on the shared future `principal` which had its value calculated by our for loop. The program will wait here until the entire dataflow tree has been calculated and the value assigned to `result`. The program then prints out the final value of the investment and the amount of interest made by subtracting the final value of the investment from the initial value of the investment.

## 2.2.7 Local to remote

When developers write code they typically begin with a simple serial code and build upon it until all of the required functionality is present. The following set of examples were developed to demonstrate this iterative process of evolving a simple serial program to an efficient, fully-distributed *HPX* application. For this demonstration, we implemented a 1D heat distribution problem. This calculation simulates the diffusion of heat across a ring from an initialized state to some user-defined point in the future. It does this by breaking each portion of the ring into discrete segments and using the current segment's temperature and the temperature of the surrounding segments to calculate the temperature of the current segment in the next timestep as shown by Fig. 2.2 below.

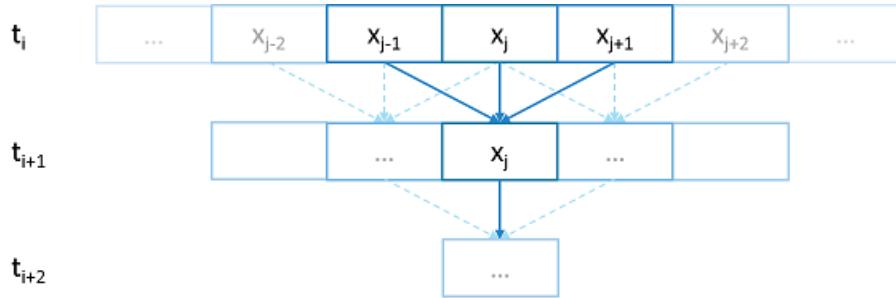

Fig. 2.2: Heat diffusion example program flow.

We parallelize this code over the following eight examples:

- Example 1
- Example 2
- Example 3
- Example 4
- Example 5
- Example 6
- Example 7
- Example 8

The first example is straight serial code. In this code we instantiate a vector *U* that contains two vectors of doubles as seen in the structure *stepper*.

```
struct stepper
{
    // Our partition type
    typedef double partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    static double heat(double left, double middle, double right)
    {
        return middle + (k * dt / (dx * dx)) * (left - 2 * middle + right);
    }
}
```

(continues on next page)

(continued from previous page)

```

// do all the work on 'nx' data points for 'nt' time steps
space do_work(std::size_t nx, std::size_t nt)
{
    // U[t][i] is the state of position i at time t.
    std::vector<space> U(2);
    for (space& s : U)
        s.resize(nx);

    // Initial conditions: f(0, i) = i
    for (std::size_t i = 0; i != nx; ++i)
        U[0][i] = double(i);

    // Actual time step loop
    for (std::size_t t = 0; t != nt; ++t)
    {
        space const& current = U[t % 2];
        space& next = U[(t + 1) % 2];

        next[0] = heat(current[nx - 1], current[0], current[1]);

        for (std::size_t i = 1; i != nx - 1; ++i)
            next[i] = heat(current[i - 1], current[i], current[i + 1]);

        next[nx - 1] = heat(current[nx - 2], current[nx - 1], current[0]);
    }

    // Return the solution at time-step 'nt'.
    return U[nt % 2];
}
};

```

Each element in the vector of doubles represents a single grid point. To calculate the change in heat distribution, the temperature of each grid point, along with its neighbors, is passed to the function `heat`. In order to improve readability, references named `current` and `next` are created which, depending on the time step, point to the first and second vector of doubles. The first vector of doubles is initialized with a simple heat ramp. After calling the `heat` function with the data in the `current` vector, the results are placed into the `next` vector.

In example 2 we employ a technique called futurization. Futurization is a method by which we can easily transform a code that is serially executed into a code that creates asynchronous threads. In the simplest case this involves replacing a variable with a future to a variable, a function with a future to a function, and adding a `.get()` at the point where a value is actually needed. The code below shows how this technique was applied to the `struct stepper`.

```

struct stepper
{
    // Our partition type
    typedef hpx::shared_future<double> partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    static double heat(double left, double middle, double right)
    {

```

(continues on next page)

(continued from previous page)

```

    return middle + (k * dt / (dx * dx)) * (left - 2 * middle + right);
}

// do all the work on 'nx' data points for 'nt' time steps
hpx::future<space> do_work(std::size_t nx, std::size_t nt)
{
    using hpx::dataflow;
    using hpx::unwrapping;

    // U[t][i] is the state of position i at time t.
    std::vector<space> U(2);
    for (space& s : U)
        s.resize(nx);

    // Initial conditions: f(0, i) = i
    for (std::size_t i = 0; i != nx; ++i)
        U[0][i] = hpx::make_ready_future(double(i));

    auto Op = unwrapping(&stepper::heat);

    // Actual time step loop
    for (std::size_t t = 0; t != nt; ++t)
    {
        space const& current = U[t % 2];
        space& next = U[(t + 1) % 2];

        // WHEN U[t][i-1], U[t][i], and U[t][i+1] have been computed, THEN we
        // can compute U[t+1][i]
        for (std::size_t i = 0; i != nx; ++i)
        {
            next[i] =
                dataflow(hpx::launch::async, Op,
                         current[idx(i, -1, nx)],
                         current[i], current[idx(i, +1, nx)]);
        }
    }

    // Now the asynchronous computation is running; the above for-loop does not
    // wait on anything. There is no implicit waiting at the end of each timestep;
    // the computation of each U[t][i] will begin as soon as its dependencies
    // are ready and hardware is available.

    // Return the solution at time-step 'nt'.
    return hpx::when_all(U[nt % 2]);
}
};

```

In example 2, we redefine our partition type as a `shared_future` and, in `main`, create the object `result`, which is a future to a vector of partitions. We use `result` to represent the last vector in a string of vectors created for each timestep. In order to move to the next timestep, the values of a partition and its neighbors must be passed to `heat` once the futures that contain them are ready. In HPX, we have an LCO (Local Control Object) named Dataflow that assists the programmer in expressing this dependency. Dataflow allows us to pass the results of a set of futures to a specified function when the futures are ready. Dataflow takes three types of arguments, one which instructs the dataflow on how to perform the function call (async or sync), the function to call (in this case `Op`), and futures to the arguments that will

be passed to the function. When called, dataflow immediately returns a future to the result of the specified function. This allows users to string dataflows together and construct an execution tree.

After the values of the futures in dataflow are ready, the values must be pulled out of the future container to be passed to the function `heat`. In order to do this, we use the HPX facility `unwrapping`, which underneath calls `.get()` on each of the futures so that the function `heat` will be passed doubles and not futures to doubles.

By setting up the algorithm this way, the program will be able to execute as quickly as the dependencies of each future are met. Unfortunately, this example runs terribly slow. This increase in execution time is caused by the overheads needed to create a future for each data point. Because the work done within each call to `heat` is very small, the overhead of creating and scheduling each of the three futures is greater than that of the actual useful work! In order to amortize the overheads of our synchronization techniques, we need to be able to control the amount of work that will be done with each future. We call this amount of work per overhead grain size.

In example 3, we return to our serial code to figure out how to control the grain size of our program. The strategy that we employ is to create “partitions” of data points. The user can define how many partitions are created and how many data points are contained in each partition. This is accomplished by creating the `struct partition`, which contains a member object `data_`, a vector of doubles that holds the data points assigned to a particular instance of `partition`.

In example 4, we take advantage of the partition setup by redefining `space` to be a vector of `shared_futures` with each future representing a partition. In this manner, each future represents several data points. Because the user can define how many data points are in each partition, and, therefore, how many data points are represented by one future, a user can control the grainsize of the simulation. The rest of the code is then futurized in the same manner as example 2. It should be noted how strikingly similar example 4 is to example 2.

Example 4 finally shows good results. This code scales equivalently to the OpenMP version. While these results are promising, there are more opportunities to improve the application’s scalability. Currently, this code only runs on one `locality`, but to get the full benefit of `HPX`, we need to be able to distribute the work to other machines in a cluster. We begin to add this functionality in example 5.

In order to run on a distributed system, a large amount of boilerplate code must be added. Fortunately, `HPX` provides us with the concept of a `component`, which saves us from having to write quite as much code. A component is an object that can be remotely accessed using its global address. Components are made of two parts: a server and a client class. While the client class is not required, abstracting the server behind a client allows us to ensure type safety instead of having to pass around pointers to global objects. Example 5 renames example 4’s `struct partition` to `partition_data` and adds serialization support. Next, we add the server side representation of the data in the structure `partition_server`. `Partition_server` inherits from `hpx::components::component_base`, which contains a server-side component boilerplate. The boilerplate code allows a component’s public members to be accessible anywhere on the machine via its Global Identifier (GID). To encapsulate the component, we create a client side helper class. This object allows us to create new instances of our component and access its members without having to know its GID. In addition, we are using the client class to assist us with managing our asynchrony. For example, our client class `partition`’s member function `get_data()` returns a future to `partition_data` `get_data()`. This struct inherits its boilerplate code from `hpx::components::client_base`.

In the structure `stepper`, we have also had to make some changes to accommodate a distributed environment. In order to get the data from a particular neighboring partition, which could be remote, we must retrieve the data from all of the neighboring partitions. These retrievals are asynchronous and the function `heat_part_data`, which, amongst other things, calls `heat`, should not be called unless the data from the neighboring partitions have arrived. Therefore, it should come as no surprise that we synchronize this operation with another instance of dataflow (found in `heat_part`). This dataflow receives futures to the data in the current and surrounding partitions by calling `get_data()` on each respective partition. When these futures are ready, dataflow passes them to the `unwrapping` function, which extracts the `shared_array` of doubles and passes them to the lambda. The lambda calls `heat_part_data` on the `locality`, which the middle partition is on.

Although this example could run distributed, it only runs on one `locality`, as it always uses `hpx::find_here()` as the target for the functions to run on.

In example 6, we begin to distribute the partition data on different nodes. This is accomplished in

`stepper::do_work()` by passing the GID of the `locality` where we wish to create the partition to the partition constructor.

```
for (std::size_t i = 0; i != np; ++i)
    U[0][i] = partition(localities[locidx(i, np, nl)], nx, double(i));
```

We distribute the partitions evenly based on the number of localities used, which is described in the function `locidx`. Because some of the data needed to update the partition in `heat_part` could now be on a new `locality`, we must devise a way of moving data to the `locality` of the middle partition. We accomplished this by adding a switch in the function `get_data()` that returns the end element of the buffer `data_` if it is from the left partition or the first element of the buffer if the data is from the right partition. In this way only the necessary elements, not the whole buffer, are exchanged between nodes. The reader should be reminded that this exchange of end elements occurs in the function `get_data()` and, therefore, is executed asynchronously.

Now that we have the code running in distributed, it is time to make some optimizations. The function `heat_part` spends most of its time on two tasks: retrieving remote data and working on the data in the middle partition. Because we know that the data for the middle partition is local, we can overlap the work on the middle partition with that of the possibly remote call of `get_data()`. This algorithmic change, which was implemented in example 7, can be seen below:

```
// The partitioned operator, it invokes the heat operator above on all elements
// of a partition.
static partition heat_part(
    partition const& left, partition const& middle, partition const& right)
{
    using hpx::dataflow;
    using hpx::unwrapping;

    hpx::shared_future<partition_data> middle_data =
        middle.get_data(partition_server::middle_partition);

    hpx::future<partition_data> next_middle = middle_data.then(
        unwrapping([middle](partition_data const& m) -> partition_data {
            HPX_UNUSED(middle);

            // All local operations are performed once the middle data of
            // the previous time step becomes available.
            std::size_t size = m.size();
            partition_data next(size);
            for (std::size_t i = 1; i != size - 1; ++i)
                next[i] = heat(m[i - 1], m[i], m[i + 1]);
            return next;
        }));
    return dataflow(hpx::launch::async,
        unwrapping([left, middle, right](partition_data next,
            partition_data const& l, partition_data const& m,
            partition_data const& r) -> partition {
            HPX_UNUSED(left);
            HPX_UNUSED(right);

            // Calculate the missing boundary elements once the
            // corresponding data has become available.
            std::size_t size = m.size();
        }));
}
```

(continues on next page)

(continued from previous page)

```

next[0] = heat(l[size - 1], m[0], m[1]);
next[size - 1] = heat(m[size - 2], m[size - 1], r[0]);

    // The new partition_data will be allocated on the same locality
    // as 'middle'.
    return partition(middle.get_id(), std::move(next));
},
std::move(next_middle),
left.get_data(partition_server::left_partition), middle_data,
right.get_data(partition_server::right_partition));
}

```

Example 8 completes the futurization process and utilizes the full potential of *HPX* by distributing the program flow to multiple localities, usually defined as nodes in a cluster. It accomplishes this task by running an instance of *HPX* main on each *locality*. In order to coordinate the execution of the program, the `struct stepper` is wrapped into a component. In this way, each *locality* contains an instance of stepper that executes its own instance of the function `do_work()`. This scheme does create an interesting synchronization problem that must be solved. When the program flow was being coordinated on the head node, the GID of each component was known. However, when we distribute the program flow, each partition has no notion of the GID of its neighbor if the next partition is on another *locality*. In order to make the GIDs of neighboring partitions visible to each other, we created two buffers to store the GIDs of the remote neighboring partitions on the left and right respectively. These buffers are filled by sending the GID of newly created edge partitions to the right and left buffers of the neighboring localities.

In order to finish the simulation, the solution vectors named `result` are then gathered together on *locality* 0 and added into a vector of spaces `overall_result` using the *HPX* functions `gather_id` and `gather_here`.

Example 8 completes this example series, which takes the serial code of example 1 and incrementally morphs it into a fully distributed parallel code. This evolution was guided by the simple principles of futurization, the knowledge of grainsize, and utilization of components. Applying these techniques easily facilitates the scalable parallelization of most applications.

## 2.2.8 Serializing user-defined types

In order to facilitate the sending and receiving of complex datatypes *HPX* provides a serialization abstraction.

Just like boost, hpx allows users to serialize user-defined types by either providing the serializer as a member function or defining the serialization as a free function.

**Unlike Boost HPX doesn't acknowledge second unsigned int parameter, it is solely there to preserve API compatibility with Boost Serialization**

This tutorial was heavily inspired by Boost's serialization concepts<sup>13</sup>.

<sup>13</sup> [https://www.boost.org/doc/libs/1\\_79\\_0/libs/serialization/doc/serialization.html](https://www.boost.org/doc/libs/1_79_0/libs/serialization/doc/serialization.html)

## Setup

The source code for this example can be found here: `custom_serialization.cpp`.

To compile this program, go to your *HPX* build directory (see [Building HPX](#) for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.custom_serialization
```

To run the program type:

```
$ ./bin/custom_serialization
```

This should print:

```
Rectangle(Point(x=0,y=0),Point(x=0,y=5))
gravity.g = 9.81%
```

## Serialization Requirements

In order to serialize objects in *HPX*, at least one of the following criteria must be met:

In the case of default constructible objects:

- The object is an empty type.
- Has a serialization function as shown in this tutorial.
- All members are accessible publicly and they can be used in structured binding contexts.

Otherwise:

- They need to have special serialization support.

## Member function serialization

```
struct point_member_serialization
{
    int x{0};
    int y{0};

    // Required when defining the serialization function as private
    // In this case it isn't
    // Provides serialization access to HPX
    friend class hpx::serialization::access;

    // Second argument exists solely for compatibility with boost serialize
    // it is NOT processed by HPX in any way.
    template <typename Archive>
    void serialize(Archive& ar, const unsigned int)
    {
        // clang-format off
        ar & x & y;
        // clang-format on
    }
}
```

(continues on next page)

(continued from previous page)

```
};

// Allow bitwise serialization
HPX_IS_BITWISE_SERIALIZABLE(point_member_serialization)
```

Notice that `point_member_serialization` is defined as bitwise serializable (see [Bitwise serialization for bitwise copyable data](#) for more details). HPX is also able to recursively serialize composite classes and structs given that its members are serializable.

```
struct rectangle_member_serialization
{
    point_member_serialization top_left;
    point_member_serialization lower_right;

    template <typename Archive>
    void serialize(Archive& ar, const unsigned int)
    {
        // clang-format off
        ar & top_left & lower_right;
        // clang-format on
    }
};
```

## Free function serialization

In order to decouple your models from HPX, HPX also allows for the definition of free function serializers.

```
struct rectangle_free
{
    point_member_serialization top_left;
    point_member_serialization lower_right;
};

template <typename Archive>
void serialize(Archive& ar, rectangle_free& pt, const unsigned int)
{
    // clang-format off
    ar & pt.lower_right & pt.top_left;
    // clang-format on
}
```

Even if you can't modify a class to befriend it, you can still be able to serialize your class provided that your class is default constructable and you are able to reconstruct it yourself.

```
class point_class
{
public:
    point_class(int x, int y)
        : x(x)
        , y(y)
    {
```

(continues on next page)

(continued from previous page)

```

}

point_class() = default;

[[nodiscard]] int get_x() const noexcept
{
    return x;
}

[[nodiscard]] int get_y() const noexcept
{
    return y;
}

private:
    int x;
    int y;
};

template <typename Archive>
void load(Archive& ar, point_class& pt, const unsigned int)
{
    int x, y;
    ar >> x >> y;
    pt = point_class(x, y);
}

template <typename Archive>
void save(Archive& ar, point_class const& pt, const unsigned int)
{
    ar << pt.get_x() << pt.get_y();
}

// This tells HPX that you have split your serialize function into
// load and save
HPX_SERIALIZATION_SPLIT_FREE(point_class)

```

## Serializing non default constructable classes

Some classes don't provide any default constructor.

```

class planet_weight_calculator
{
public:
    explicit planet_weight_calculator(double g)
        : g(g)
    {

        template <class Archive>
        friend void save_construct_data(

```

(continues on next page)

(continued from previous page)

```

Archive&, planet_weight_calculator const*, unsigned int);

[[nodiscard]] double get_g() const
{
    return g;
}

private:
// Provides serialization access to HPX
friend class hpx::serialization::access;
template <class Archive>
void serialize(Archive&, const unsigned int)
{
    // Serialization will be done in the save_construct_data
    // Still needs to be defined
}

double g;
};

```

In this case you have to define a `save_construct_data` and `load_construct_data` in which you do the serialization yourself.

```

template <class Archive>
inline void save_construct_data(Archive& ar,
    planet_weight_calculator const* weight_calc, const unsigned int)
{
    ar << weight_calc->g;      // Do all of your serialization here
}

template <class Archive>
inline void load_construct_data(
    Archive& ar, planet_weight_calculator* weight_calc, const unsigned int)
{
    double g;
    ar >> g;

    // ::new(ptr) construct new object at given address
    ::new (weight_calc) planet_weight_calculator(g);
}

```

## Bitwise serialization for bitwise copyable data

When sending non arithmetic types not defined by `std::is_arithmetic`<sup>14</sup>, HPX has to (de)serialize each object separately. However, if the class you are trying to send classes consists only of bitwise copyable datatypes, you may mark your class as such. Then HPX will serialize your object bitwise instead of element wise. This has enormous benefits, especially when sending a vector/array of your class. To define your class as such you need to call `HPX_IS_BITWISE_SERIALIZABLE(T)` with your desired custom class.

<sup>14</sup> [https://en.cppreference.com/w/cpp/types/is\\_arithmetic](https://en.cppreference.com/w/cpp/types/is_arithmetic)

```
struct point_member_serialization
{
    int x{0};
    int y{0};

    // Required when defining the serialization function as private
    // In this case it isn't
    // Provides serialization access to HPX
    friend class hpx::serialization::access;

    // Second argument exists solely for compatibility with boost serialize
    // it is NOT processed by HPX in any way.
    template <typename Archive>
    void serialize(Archive& ar, const unsigned int)
    {
        // clang-format off
        ar & x & y;
        // clang-format on
    }
};

// Allow bitwise serialization
HPX_IS_BITWISE_SERIALIZABLE(point_member_serialization)
```

## 2.3 Manual

The manual is your comprehensive guide to *HPX*. It contains detailed information on how to build and use *HPX* in different scenarios.

### 2.3.1 Prerequisites

#### Supported platforms

At this time, *HPX* supports the following platforms. Other platforms may work, but we do not test *HPX* with other platforms, so please be warned.

Table 2.1: Supported Platforms for *HPX*

Name	Minimum Version	Architectures
Linux	2.6	x86-32, x86-64, k1om
BlueGeneQ	V1R2M0	PowerPC A2
Windows	Any Windows system	x86-32, x86-64
Mac OSX	Any OSX system	x86-64

## Supported compilers

The table below shows the supported compilers for *HPX*.

Table 2.2: Supported Compilers for *HPX*

Name	Minimum Version
GNU Compiler Collection (g++) <sup>15</sup>	8.0
clang: a C language family frontend for LLVM <sup>16</sup>	8.0
Visual C++ <sup>17</sup> (x64)	2015

## Software and libraries

The table below presents all the necessary prerequisites for building *HPX*.

Table 2.3: Software prerequisites for *HPX*

	Name	Minimum Version
<b>Build System</b>	CMake <sup>18</sup>	3.18
<b>Required Libraries</b>	Boost <sup>19</sup>	1.71.0
	Portable Hardware Locality (HWLOC) <sup>20</sup>	1.5
	Asio <sup>21</sup>	1.12.0

The most important dependencies are Boost<sup>22</sup> and Portable Hardware Locality (HWLOC)<sup>23</sup>. The installation of Boost is described in detail in Boost's Getting Started<sup>24</sup> document. A recent version of hwloc is required in order to support thread pinning and NUMA awareness and can be found in Hwloc Downloads<sup>25</sup>.

*HPX* is written in 99.99% Standard C++ (the remaining 0.01% is platform specific assembly code). As such, *HPX* is compilable with almost any standards compliant C++ compiler. The code base takes advantage of C++ language and standard library features when available.

---

**Note:** When building Boost using gcc, please note that it is required to specify a `cxxflags=-std=c++17` command line argument to `b2` (`bjam`).

---

**Note:** In most configurations, *HPX* depends only on header-only Boost. Boost.Filesystem is required if the standard library does not support filesystem. The following are not needed by default, but are required in certain configurations: Boost.Chrono, Boost.DateTime, Boost.Log, Boost.LogSetup, Boost.Regex, and Boost.Thread.

---

<sup>15</sup> <https://gcc.gnu.org>

<sup>16</sup> <https://clang.llvm.org/>

<sup>17</sup> <https://msdn.microsoft.com/en-us/visualc/default.aspx>

<sup>18</sup> <https://www.cmake.org>

<sup>19</sup> <https://www.boost.org/>

<sup>20</sup> <https://www.open-mpi.org/projects/hwloc/>

<sup>21</sup> <https://think-async.com/asio/>

<sup>22</sup> <https://www.boost.org/>

<sup>23</sup> <https://www.open-mpi.org/projects/hwloc/>

<sup>24</sup> [https://www.boost.org/more/getting\\_started/index.html](https://www.boost.org/more/getting_started/index.html)

<sup>25</sup> <https://www.open-mpi.org/software/hwloc/v1.11>

Depending on the options you chose while building and installing *HPX*, you will find that *HPX* may depend on several other libraries such as those listed below.

---

**Note:** In order to use a high speed parcelport, we currently recommend configuring *HPX* to use MPI so that MPI can be used for communication between different localities. Please set the CMake variable `MPI_CXX_COMPILER` to your MPI C++ compiler wrapper if not detected automatically.

---

Table 2.4: Optional software prerequisites for *HPX*

Name	Minimum version
<code>google-perfetto</code> <sup>26</sup>	1.7.1
<code>jemalloc</code> <sup>27</sup>	2.1.0
<code>mi-malloc</code> <sup>28</sup>	1.0.0
Performance Application Programming Interface (PAPI)	

### 2.3.2 Getting *HPX*

Download a tarball of the latest release from [HPX Downloads](#)<sup>29</sup> and unpack it or clone the repository directly using git:

```
$ git clone https://github.com/STELLAR-GROUP/hpx.git
```

It is also recommended that you check out the latest stable tag:

```
$ cd hpx
```

```
$ git checkout 1.9.0
```

### 2.3.3 Building *HPX*

#### Basic information

The build system for *HPX* is based on [CMake](#)<sup>30</sup>, a cross-platform build-generator tool which is not responsible for building the project but rather generates the files needed by your build tool (GNU make, Visual Studio, etc.) for building *HPX*. If CMake is not already installed in your system, you can download it and install it here: [CMake Downloads](#)<sup>31</sup>.

Once CMake has been run, the build process can be started. The *HPX* build process is highly configurable through CMake, and various CMake variables influence the build process. The build process consists of the following parts:

- The *HPX* core libraries (target `core`): This forms the basic set of *HPX* libraries.
- *HPX* Examples (target `examples`): This target is enabled by default and builds all *HPX* examples (disable by setting `HPX_WITH_EXAMPLES:BOOL=Off`). *HPX* examples are part of the `all` target and are included in the installation if enabled.
- *HPX* Tests (target `tests`): This target builds the *HPX* test suite and is enabled by default (disable by setting `HPX_WITH_TESTS:BOOL=Off`). They are not built by the `all` target and have to be built separately.

<sup>26</sup> <https://code.google.com/p/gperftools>

<sup>27</sup> <http://jemalloc.net>

<sup>28</sup> <http://microsoft.github.io/mimalloc/>

<sup>29</sup> <https://hpx.stellar-group.org/downloads/>

<sup>30</sup> <https://www.cmake.org>

<sup>31</sup> <https://www.cmake.org/cmake/resources/software.html>

- *HPX Documentation (target docs)*: This target builds the documentation, and is not enabled by default (enable by setting `HPX_WITH_DOCUMENTATION:BOOL=On`). For more information see [Documentation](#).

For a complete list of available CMake variables that influence the build of *HPX*, see [CMake variables used to configure HPX](#).

The variables can be used to refine the recipes that can be found at [Platform specific build recipes](#) which show some basic steps on how to build *HPX* for a specific platform.

In order to use *HPX*, only the core libraries are required. In order to use the optional libraries, you need to specify them as link dependencies in your build (See [Creating HPX projects](#)).

## Most important CMake options

While building *HPX*, you are provided with multiple CMake options which correspond to different configurations. Below, there is a set of the most important and frequently used CMake options.

### `HPX_WITH_MALLOC`

Use a custom allocator. Using a custom allocator tuned for multithreaded applications is very important for the performance of *HPX* applications. When debugging applications, it's useful to set this to `system`, as custom allocators can hide some memory-related bugs. Note that setting this to something other than `system` requires an external dependency.

### `HPX_WITH_CUDA`

Enable support for CUDA. Use `CMAKE_CUDA_COMPILER` to set the CUDA compiler. This is a standard CMake variable, like `CMAKE_CXX_COMPILER`.

### `HPX_WITH_PARCELPORT_MPI`

Enable the MPI parcelport. This enables the use of MPI for the networking operations in the *HPX* runtime. The default value is OFF because it's not available on all systems and/or requires another dependency. However, it is the recommended parcelport.

### `HPX_WITH_PARCELPORT_TCP`

Enable the TCP parcelport. Enables the use of TCP for networking in the runtime. The default value is ON. However, it's only recommended for debugging purposes, as it is slower than the MPI parcelport.

### `HPX_WITH_APEX`

Enable APEX integration. [APEX](#)<sup>32</sup> can be used to profile *HPX* applications. In particular, it provides information about individual tasks in the *HPX* runtime.

### `HPX_WITH_GENERIC_CONTEXT_COROUTINES`

Enable Boost. Context for task context switching. It must be enabled for non-x86 architectures such as ARM and Power.

### `HPX_WITH_MAX_CPU_COUNT`

Set the maximum CPU count supported by *HPX*. The default value is 64, and should be set to a number at least as high as the number of cores on a system including virtual cores such as hyperthreads.

### `HPX_WITH_CXX_STANDARD`

Set a specific C++ standard version e.g. `HPX_WITH_CXX_STANDARD=20`. The default and minimum value is 17.

### `HPX_WITH_EXAMPLES`

Build examples.

---

<sup>32</sup> <https://uo-oaciss.github.io/apex/quickstarthpx/>

## HPX\_WITH\_TESTS

Build tests.

For a complete list of available CMake variables that influence the build of *HPX*, see [CMake variables used to configure HPX](#).

## Build types

CMake can be configured to generate project files suitable for builds that have enabled debugging support or for an optimized build (without debugging support). The CMake variable used to set the build type is `CMAKE_BUILD_TYPE` (for more information see the [CMake Documentation](#)<sup>33</sup>). Available build types are:

- **Debug:** Full debug symbols are available as well as additional assertions to help debugging. To enable the debug build type for the *HPX* API, the C++ Macro `HPX_DEBUG` is defined.
- **RelWithDebInfo:** Release build with debugging symbols. This is most useful for profiling applications
- **Release:** Release build. This disables assertions and enables default compiler optimizations.
- **RelMinSize:** Release build with optimizations for small binary sizes.

---

**Important:** We currently don't guarantee ABI compatibility between Debug and Release builds. Please make sure that applications built against *HPX* use the same build type as you used to build *HPX*. For CMake builds, this means that the `CMAKE_BUILD_TYPE` variables have to match and for projects not using [CMake](#)<sup>34</sup>, the `HPX_DEBUG` macro has to be set in debug mode.

---

## Platform specific build recipes

### Unix variants

Once you have the source code and the dependencies and assuming all your dependencies are in paths known to CMake, the following gets you started:

1. First, set up a separate build directory to configure the project:

```
$ mkdir build && cd build
```

2. To configure the project you have the following options:

- To build the core *HPX* libraries and examples, and install them to your chosen location (recommended):

```
$ cmake -DCMAKE_INSTALL_PREFIX=/install/path ..
```

---

**Tip:** If you want to change CMake variables for your build, it is usually a good idea to start with a clean build directory to avoid configuration problems. It is especially important that you use a clean build directory when changing between Release and Debug modes.

---

- To install *HPX* to the default system folders, simply leave out the `CMAKE_INSTALL_PREFIX` option:

```
$ cmake ..
```

<sup>33</sup> [https://cmake.org/cmake/help/latest/variable/CMAKE\\_BUILD\\_TYPE.html](https://cmake.org/cmake/help/latest/variable/CMAKE_BUILD_TYPE.html)

<sup>34</sup> <https://www.cmake.org>

- If your dependencies are in custom locations, you may need to tell CMake where to find them by passing one or more options to CMake as shown below:

```
$ cmake -DBOOST_ROOT=/path/to/boost
      -DHWLOC_ROOT=/path/to/hwloc
      -DTCMALLOC_ROOT=/path/to/tcmalloc
      -DJEMALLOC_ROOT=/path/to/jemalloc
      [other CMake variable definitions]
      /path/to/source/tree
```

For instance:

```
$ cmake -DBOOST_ROOT=~/packages/boost -DHWLOC_ROOT=~/packages/hwloc -DCMAKE_
      -INSTALL_PREFIX=~/packages/hpx ~/downloads/hpx_1.5.1
```

- If you want to try *HPX* without using a custom allocator pass `-DHPX_WITH_MALLOC=system` to CMake:

```
$ cmake -DCMAKE_INSTALL_PREFIX=/install/path -DHPX_WITH_MALLOC=system ..
```

---

**Note:** Please pay special attention to the section about `HPX_WITH_MALLOC:STRING` as this is crucial for getting decent performance.

---

**Important:** If you are building *HPX* for a system with more than 64 processing units, you must change the CMake variable `HPX_WITH_MAX_CPU_COUNT` (to a value at least as big as the number of (virtual) cores on your system). Note that the default value is 64.

**Caution:** Compiling and linking *HPX* needs a considerable amount of memory. It is advisable that at least 2 GB of memory per parallel process is available.

3. Once the configuration is complete, to build the project you run:

```
$ cmake --build . --target install
```

## Windows

---

**Note:** The following build recipes are mostly user-contributed and may be outdated. We always welcome updated and new build recipes.

---

To build *HPX* under Windows 10 x64 with Visual Studio 2015:

- Download the CMake V3.18.1 installer (or latest version) from [here](#)<sup>35</sup>
- Download the hwloc V1.11.0 (or the latest version) from [here](#)<sup>36</sup> and unpack it.
- Download the latest Boost libraries from [here](#)<sup>37</sup> and unpack them.

<sup>35</sup> <https://blog.kitware.com/cmake-3-18-1-available-for-download/>

<sup>36</sup> <http://www.open-mpi.org/software/hwloc/v1.11/downloads/hwloc-win64-build-1.11.0.zip>

<sup>37</sup> <https://www.boost.org/users/download/>

- Build the Boost DLLs and LIBs by using these commands from Command Line (or PowerShell). Open CMD/PowerShell inside the Boost dir and type in:

```
bootstrap.bat
```

This batch file will set up everything needed to create a successful build. Now execute:

```
b2.exe link=shared variant=release,debug architecture=x86 address-model=64
→threading=multi --build-type=complete install
```

This command will start a (very long) build of all available Boost libraries. Please, be patient.

- Open CMake-GUI.exe and set up your source directory (input field ‘Where is the source code’) to the *base directory* of the source code you downloaded from HPX’s GitHub pages. Here’s an example of CMake path settings, which point to the Documents/GitHub/hpx folder:

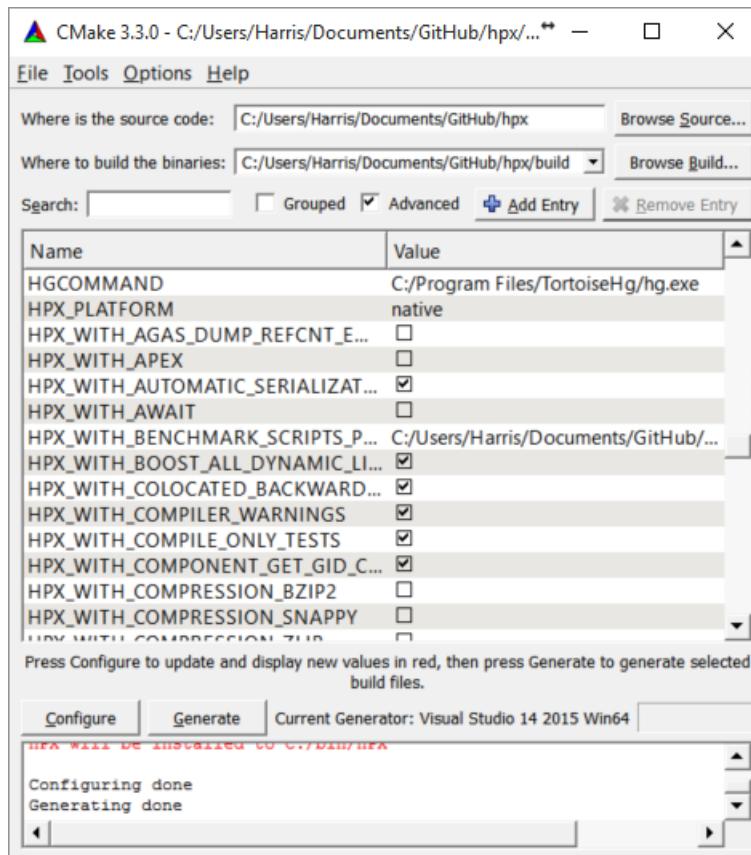

Fig. 2.3: Example CMake path settings.

Inside ‘Where is the source-code’ enter the base directory of your HPX source directory (do not enter the “src” sub-directory!). Inside ‘Where to build the binaries’ you should put in the path where all the building processes will happen. This is important because the building machinery will do an “out-of-tree” build. CMake will not touch or change the original source files in any way. Instead, it will generate Visual Studio Solution Files, which will build HPX packages out of the HPX source tree.

- Set three new environment variables (in CMake, not in Windows environment): BOOST\_ROOT, HWLOC\_ROOT, CMAKE\_INSTALL\_PREFIX. The meaning of these variables is as follows:

- BOOST\_ROOT the HPX root directory of the unpacked Boost headers/cpp files.

- `HWLOC_ROOT` the *HPX* root directory of the unpacked Portable Hardware Locality files.
- `CMAKE_INSTALL_PREFIX` the *HPX* root directory where the future builds of *HPX* should be installed.

---

**Note:** *HPX* is a very large software collection, so it is not recommended to use the default `C:\Program Files\hpx`. Many users may prefer to use simpler paths *without* whitespace, like `C:\bin\hpx` or `D:\bin\hpx` etc.

---

To insert new env-vars click on “Add Entry” and then insert the name inside “Name”, select PATH as Type and put the path-name in the “Path” text field. Repeat this for the first three variables.

This is how variable insertion will look:

Fig. 2.4: Example CMake adding entry.

Alternatively, users could provide `BOOST_LIBRARYDIR` instead of `BOOST_ROOT`; the difference is that `BOOST_LIBRARYDIR` should point to the subdirectory inside Boost root where all the compiled DLLs/LIBs are. For example, `BOOST_LIBRARYDIR` may point to the `bin.v2` subdirectory under the Boost roottdir. It is important to keep the meanings of these two variables separated from each other: `BOOST_DIR` points to the ROOT folder of the Boost library. `BOOST_LIBRARYDIR` points to the subdir inside the Boost root folder where the compiled binaries are.

- Click the ‘Configure’ button of CMake-GUI. You will be immediately presented with a small window where you can select the C++ compiler to be used within Visual Studio. This has been tested using the latest v14 (a.k.a C++ 2015) but older versions should be sufficient too. Make sure to select the 64Bit compiler.
- After the generate process has finished successfully, click the ‘Generate’ button. Now, CMake will put new VS

Solution files into the BUILD folder you selected at the beginning.

- Open Visual Studio and load the HPX.sln from your build folder.
- Go to CMakePredefinedTargets and build the INSTALL project:

Fig. 2.5: Visual Studio INSTALL target.

It will take some time to compile everything, and in the end you should see an output similar to this one:

## Tests and examples

### Running tests

To build the tests:

```
$ cmake --build . --target tests
```

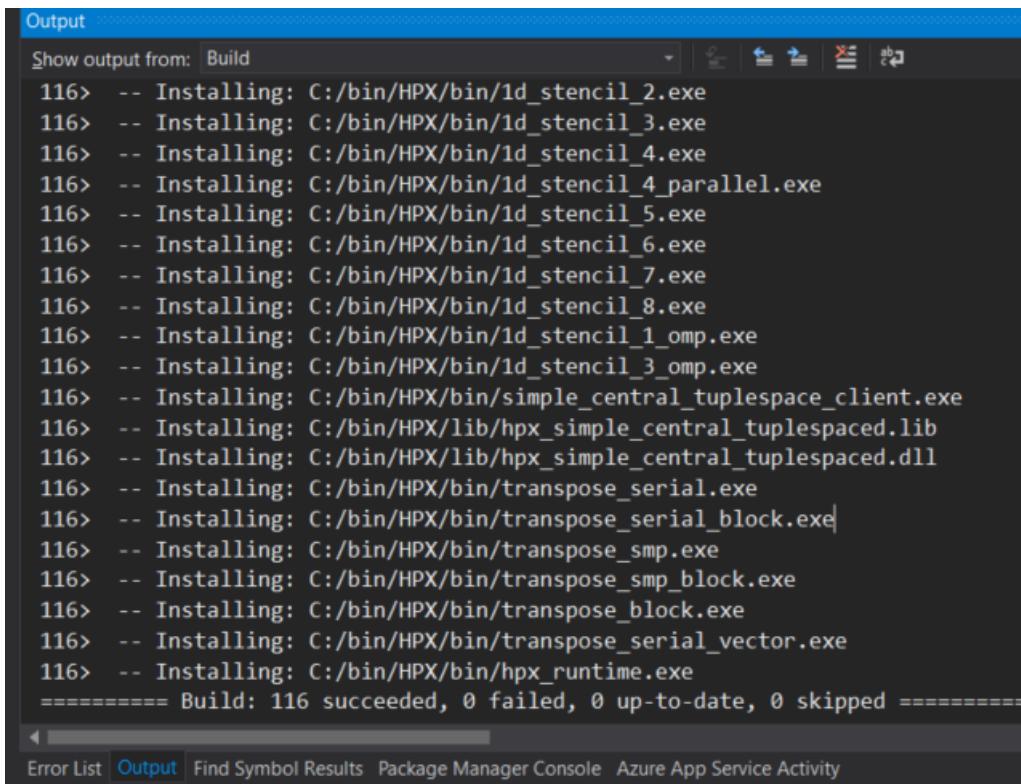

To control which tests to run use `ctest`:

- To run single tests, for example a test for `for_loop`:

```
$ ctest --output-on-failure -R tests.unit.modules.algorithms.for_loop
```

- To run a whole group of tests:

```
$ ctest --output-on-failure -R tests.unit
```

The screenshot shows the Visual Studio Output window with the title 'Output' at the top. Below it, a dropdown menu says 'Show output from: Build'. The main area contains a log of 116 installations of various HPX executables and libraries. The log includes names like '1d\_stencil\_2.exe', '1d\_stencil\_3.exe', '1d\_stencil\_4.exe', etc., followed by 'simple\_central\_tuplespace\_client.exe', 'hpx\_simple\_central\_tuplespaced.lib', and 'hpx\_simple\_central\_tuplespaced.dll'. It also lists transpose-related executables such as 'transpose\_serial.exe', 'transpose\_serial\_block.exe', 'transpose\_smp.exe', 'transpose\_smp\_block.exe', and 'transpose\_block.exe'. The log concludes with a summary: 'Build: 116 succeeded, 0 failed, 0 up-to-date, 0 skipped ======='.

Fig. 2.6: Visual Studio build output.

## Running examples

- To build (and install) all examples invoke:

```
$ cmake -DHPX_WITH_EXAMPLES=On .
$ make examples
$ make install
```

- To build the `hello_world_1` example run:

```
$ make hello_world_1
```

*HPX* executables end up in the `bin` directory in your build directory. You can now run `hello_world_1` and should see the following output:

```
$ ./bin/hello_world_1
Hello World!
```

You've just run an example which prints `Hello World!` from the *HPX* runtime. The source for the example is in `examples/quickstart/hello_world_1.cpp`. The `hello_world_distributed` example (also available in the `examples/quickstart` directory) is a distributed hello world program, which is described in [Remote execution with actions](#). It provides a gentle introduction to the distributed aspects of *HPX*.

---

**Tip:** Most build targets in *HPX* have two names: a simple name and a hierarchical name corresponding to what type of example or test the target is. If you are developing *HPX* it is often helpful to run `make help` to get a list of available targets. For example, `make help | grep hello_world` outputs the following:

```
... examples.quickstart.hello_world_2
... hello_world_2
... examples.quickstart.hello_world_1
... hello_world_1
... examples.quickstart.hello_world_distributed
... hello_world_distributed
```

It is also possible to build, for instance, all quickstart examples using `make examples.quickstart`.

---

### 2.3.4 CMake variables used to configure HPX

In order to configure *HPX*, you can set a variety of options to allow CMake to generate your specific makefiles/project files.

#### Variables that influence how *HPX* is built

The options are split into these categories:

- *Generic options*
- *Build Targets options*
- *Thread Manager options*
- *AGAS options*
- *Parcelport options*
- *Profiling options*
- *Debugging options*
- *Modules options*

#### Generic options

- `HPX_WITH_AUTOMATIC_SERIALIZATION_REGISTRATION:BOOL`
- `HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH`
- `HPX_WITH_BUILD_BINARY_PACKAGE:BOOL`
- `HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL`
- `HPX_WITH_COMPILER_WARNINGS:BOOL`
- `HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL`
- `HPX_WITH_COMPRESSION_BZIP2:BOOL`
- `HPX_WITH_COMPRESSION_SNAPPY:BOOL`
- `HPX_WITH_COMPRESSION_ZLIB:BOOL`
- `HPX_WITH_CUDA:BOOL`
- `HPX_WITH_CXX_STANDARD:STRING`
- `HPX_WITH_DATAPAR:BOOL`

- *HPX\_WITH\_DATAPAR\_BACKEND:STRING*
- *HPX\_WITH\_DATAPAR\_VC\_NO\_LIBRARY:BOOL*
- *HPX\_WITH\_DEPRECATED\_WARNINGS:BOOL*
- *HPX\_WITH\_DISABLED\_SIGNAL\_EXCEPTION\_HANDLERS:BOOL*
- *HPX\_WITH\_DYNAMIC\_HPX\_MAIN:BOOL*
- *HPX\_WITHFAULT\_TOLERANCE:BOOL*
- *HPX\_WITH\_FULL\_RPATH:BOOL*
- *HPX\_WITH\_GCC\_VERSION\_CHECK:BOOL*
- *HPX\_WITH\_GENERIC\_CONTEXT\_COROUTINES:BOOL*
- *HPX\_WITH\_HIDDEN\_VISIBILITY:BOOL*
- *HPX\_WITH\_HIP:BOOL*
- *HPX\_WITH\_LOGGING:BOOL*
- *HPX\_WITH\_MALLOC:STRING*
- *HPX\_WITH\_MODULES\_AS\_STATIC\_LIBRARIES:BOOL*
- *HPX\_WITH\_NICE\_THREADLEVEL:BOOL*
- *HPX\_WITH\_PARCEL\_COALESCING:BOOL*
- *HPX\_WITH\_PKGCONFIG:BOOL*
- *HPX\_WITH\_PRECOMPILED\_HEADERS:BOOL*
- *HPX\_WITH\_RUN\_MAIN\_EVERYWHERE:BOOL*
- *HPX\_WITH\_STACKOVERFLOW\_DETECTION:BOOL*
- *HPX\_WITH\_STATIC\_LINKING:BOOL*
- *HPX\_WITH\_UNITY\_BUILD:BOOL*
- *HPX\_WITH\_VIM\_YCM:BOOL*
- *HPX\_WITH\_ZERO\_COPY\_SERIALIZATION\_THRESHOLD:STRING*

**HPX\_WITH\_AUTOMATIC\_SERIALIZATION\_REGISTRATION:BOOL**

Use automatic serialization registration for actions and functions. This affects compatibility between HPX applications compiled with different compilers (default ON)

**HPX\_WITH\_BENCHMARK\_SCRIPTS\_PATH:PATH**

Directory to place batch scripts in

**HPX\_WITH\_BUILD\_BINARY\_PACKAGE:BOOL**

Build HPX on the build infrastructure on any LINUX distribution (default: OFF).

**HPX\_WITH\_CHECK\_MODULE\_DEPENDENCIES:BOOL**

Verify that no modules are cross-referenced from a different module category (default: OFF)

**HPX\_WITH\_COMPILER\_WARNINGS:BOOL**

Enable compiler warnings (default: ON)

**HPX\_WITH\_COMPILER\_WARNINGS\_AS\_ERRORS:BOOL**

Turn compiler warnings into errors (default: OFF)

**HPX\_WITH\_COMPRESSION\_BZIP2:BOOL**

Enable bzip2 compression for parcel data (default: OFF).

**HPX\_WITH\_COMPRESSION\_SNAPPY:BOOL**

Enable snappy compression for parcel data (default: OFF).

**HPX\_WITH\_COMPRESSION\_ZLIB:BOOL**

Enable zlib compression for parcel data (default: OFF).

**HPX\_WITH\_CUDA:BOOL**

Enable support for CUDA (default: OFF)

**HPX\_WITH\_CXX\_STANDARD:STRING**

Set the C++ standard to use when compiling HPX itself. (default: 17)

**HPX\_WITH\_DATAPAR:BOOL**

Enable data parallel algorithm support using Vc library (default: ON)

**HPX\_WITH\_DATAPAR\_BACKEND:STRING**

Define which vectorization library should be used. Options are: VC, EVE, STD\_EXPERIMENTAL SIMD, NONE

**HPX\_WITH\_DATAPAR\_VC\_NO\_LIBRARY:BOOL**

Don't link with the Vc static library (default: OFF)

**HPX\_WITH\_DEPRECATED\_WARNINGS:BOOL**

Enable warnings for deprecated facilities. (default: ON)

**HPX\_WITH\_DISABLED\_SIGNAL\_EXCEPTION\_HANDLERS:BOOL**

Disables the mechanism that produces debug output for caught signals and unhandled exceptions (default: OFF)

**HPX\_WITH\_DYNAMIC\_HPX\_MAIN:BOOL**

Enable dynamic overload of system `main()` (Linux and Apple only, default: ON)

**HPX\_WITH\_FAULT\_TOLERANCE:BOOL**

Build HPX to tolerate failures of nodes, i.e. ignore errors in active communication channels (default: OFF)

**HPX\_WITH\_FULL\_RPATH:BOOL**

Build and link HPX libraries and executables with full RPATHs (default: ON)

**HPX\_WITH\_GCC\_VERSION\_CHECK:BOOL**

Don't ignore version reported by gcc (default: ON)

**HPX\_WITH\_GENERIC\_CONTEXT\_COROUTINES:BOOL**

Use Boost.Context as the underlying coroutines context switch implementation.

**HPX\_WITH\_HIDDEN\_VISIBILITY:BOOL**

Use `-fvisibility=hidden` for builds on platforms which support it (default OFF)

**HPX\_WITH\_HIP:BOOL**

Enable compilation with HIPCC (default: OFF)

**HPX\_WITH\_LOGGING:BOOL**

Build HPX with logging enabled (default: ON).

**HPX\_WITH\_MALLOC:STRING**

Define which allocator should be linked in. Options are: system, tcmalloc, jemalloc, mimalloc, tbbmalloc, and custom (default is: tcmalloc)

**HPX\_WITH\_MODULES\_AS\_STATIC\_LIBRARIES:BOOL**

Compile HPX modules as STATIC (whole-archive) libraries instead of OBJECT libraries (Default: ON)

**HPX\_WITH\_NICE\_THREADLEVEL:BOOL**

Set HPX worker threads to have high NICE level (may impact performance) (default: OFF)

**HPX\_WITH\_PARCEL\_COALESCING:BOOL**

Enable the parcel coalescing plugin (default: ON).

**HPX\_WITH\_PKGCONFIG:BOOL**

Enable generation of pkgconfig files (default: ON on Linux without CUDA/HIP, otherwise OFF)

**HPX\_WITH\_PRECOMPILED\_HEADERS:BOOL**

Enable precompiled headers for certain build targets (experimental) (default OFF)

**HPX\_WITH\_RUN\_MAIN\_EVERYWHERE:BOOL**

Run hpx\_main by default on all localities (default: OFF).

**HPX\_WITH\_STACKOVERFLOW\_DETECTION:BOOL**

Enable stackoverflow detection for HPX threads/coroutines. (default: OFF, debug: ON)

**HPX\_WITH\_STATIC\_LINKING:BOOL**

Compile HPX statically linked libraries (Default: OFF)

**HPX\_WITH\_UNITY\_BUILD:BOOL**

Enable unity build for certain build targets (default OFF)

**HPX\_WITH\_VIM\_YCM:BOOL**

Generate HPX completion file for VIM YouCompleteMe plugin

**HPX\_WITH\_ZERO\_COPY\_SERIALIZATION\_THRESHOLD:STRING**

The threshold in bytes to when perform zero copy optimizations (default: 128)

## Build Targets options

- [HPX\\_WITH\\_ASIO\\_TAG:STRING](#)
- [HPX\\_WITH\\_COMPILE\\_ONLY\\_TESTS:BOOL](#)
- [HPX\\_WITH\\_DISTRIBUTED\\_RUNTIME:BOOL](#)
- [HPX\\_WITH\\_DOCUMENTATION:BOOL](#)
- [HPX\\_WITH\\_DOCUMENTATION\\_OUTPUT\\_FORMATS:STRING](#)
- [HPX\\_WITH\\_EXAMPLES:BOOL](#)
- [HPX\\_WITH\\_EXAMPLES\\_HDF5:BOOL](#)
- [HPX\\_WITH\\_EXAMPLES\\_OPENMP:BOOL](#)
- [HPX\\_WITH\\_EXAMPLES\\_QT4:BOOL](#)
- [HPX\\_WITH\\_EXAMPLES\\_QTHREADS:BOOL](#)
- [HPX\\_WITH\\_EXAMPLES\\_TBB:BOOL](#)
- [HPX\\_WITH\\_EXECUTABLE\\_PREFIX:STRING](#)
- [HPX\\_WITH\\_FAIL\\_COMPILE\\_TESTS:BOOL](#)
- [HPX\\_WITH\\_FETCH\\_ASIO:BOOL](#)

- *HPX\_WITH\_FETCH\_LCI:BOOL*
- *HPX\_WITH\_IO\_COUNTERS:BOOL*
- *HPX\_WITH\_LCI\_TAG:STRING*
- *HPX\_WITH\_TESTS:BOOL*
- *HPX\_WITH\_TESTS\_BENCHMARKS:BOOL*
- *HPX\_WITH\_TESTS\_EXAMPLES:BOOL*
- *HPX\_WITH\_TESTS\_EXTERNAL\_BUILD:BOOL*
- *HPX\_WITH\_TESTS\_HEADERS:BOOL*
- *HPX\_WITH\_TESTS\_REGRESSIONS:BOOL*
- *HPX\_WITH\_TESTS\_UNIT:BOOL*
- *HPX\_WITH\_TOOLS:BOOL*

**HPX\_WITH\_ASIO\_TAG:STRING**

Asio repository tag or branch

**HPX\_WITH\_COMPILE\_ONLY\_TESTS:BOOL**

Create build system support for compile time only HPX tests (default ON)

**HPX\_WITH\_DISTRIBUTED\_RUNTIME:BOOL**

Enable the distributed runtime (default: ON). Turning off the distributed runtime completely disallows the creation and use of components and actions. Turning this option off is experimental!

**HPX\_WITH\_DOCUMENTATION:BOOL**

Build the HPX documentation (default OFF).

**HPX\_WITH\_DOCUMENTATION\_OUTPUT\_FORMATS:STRING**

List of documentation output formats to generate. Valid options are html;singlehtml;latexpdf;man. Multiple values can be separated with semicolons. (default html).

**HPX\_WITH\_EXAMPLES:BOOL**

Build the HPX examples (default ON)

**HPX\_WITH\_EXAMPLES\_HDF5:BOOL**

Enable examples requiring HDF5 support (default: OFF).

**HPX\_WITH\_EXAMPLES\_OPENMP:BOOL**

Enable examples requiring OpenMP support (default: OFF).

**HPX\_WITH\_EXAMPLES\_QT4:BOOL**

Enable examples requiring Qt4 support (default: OFF).

**HPX\_WITH\_EXAMPLES\_QTHREADS:BOOL**

Enable examples requiring QThreads support (default: OFF).

**HPX\_WITH\_EXAMPLES\_TBB:BOOL**

Enable examples requiring TBB support (default: OFF).

**HPX\_WITH\_EXECUTABLE\_PREFIX:STRING**

Executable prefix (default none), ‘**hpx**’ useful for system install.

**HPX\_WITH\_FAIL\_COMPILE\_TESTS:BOOL**

Create build system support for fail compile HPX tests (default ON)

**HPX\_WITH\_FETCH\_ASIO:BOOL**

Use FetchContent to fetch Asio. By default an installed Asio will be used. (default: OFF)

**HPX\_WITH\_FETCH\_LCI:BOOL**

Use FetchContent to fetch LCI. By default an installed LCI will be used. (default: OFF)

**HPX\_WITH\_IO\_COUNTERS:BOOL**

Enable IO counters (default: ON)

**HPX\_WITH\_LCI\_TAG:STRING**

LCI repository tag or branch

**HPX\_WITH\_TESTS:BOOL**

Build the HPX tests (default ON)

**HPX\_WITH\_TESTS\_BENCHMARKS:BOOL**

Build HPX benchmark tests (default: ON)

**HPX\_WITH\_TESTS\_EXAMPLES:BOOL**

Add HPX examples as tests (default: ON)

**HPX\_WITH\_TESTS\_EXTERNAL\_BUILD:BOOL**

Build external cmake build tests (default: ON)

**HPX\_WITH\_TESTS\_HEADERS:BOOL**

Build HPX header tests (default: OFF)

**HPX\_WITH\_TESTS\_REGRESSIONS:BOOL**

Build HPX regression tests (default: ON)

**HPX\_WITH\_TESTS\_UNIT:BOOL**

Build HPX unit tests (default: ON)

**HPX\_WITH\_TOOLS:BOOL**

Build HPX tools (default: OFF)

## Thread Manager options

- [\*HPX\\_COROUTINES\\_WITH\\_SWAP\\_CONTEXT\\_EMULATION:BOOL\*](#)
- [\*HPX\\_WITH\\_COROUTINE\\_COUNTERS:BOOL\*](#)
- [\*HPX\\_WITH\\_IO\\_POOL:BOOL\*](#)
- [\*HPX\\_WITH\\_MAX\\_CPU\\_COUNT:STRING\*](#)
- [\*HPX\\_WITH\\_MAX\\_NUMA\\_DOMAIN\\_COUNT:STRING\*](#)
- [\*HPX\\_WITH\\_SCHEDULER\\_LOCAL\\_STORAGE:BOOL\*](#)
- [\*HPX\\_WITH\\_SPINLOCK\\_DEADLOCK\\_DETECTION:BOOL\*](#)
- [\*HPX\\_WITH\\_SPINLOCK\\_POOL\\_NUM:STRING\*](#)
- [\*HPX\\_WITH\\_STACKTRACES:BOOL\*](#)
- [\*HPX\\_WITH\\_STACKTRACES\\_DEMANGLE\\_SYMBOLS:BOOL\*](#)
- [\*HPX\\_WITH\\_STACKTRACES\\_STATIC\\_SYMBOLS:BOOL\*](#)
- [\*HPX\\_WITH\\_THREAD\\_BACKTRACE\\_DEPTH:STRING\*](#)

- `HPX_WITH_THREAD_BACKTRACE_ON_SUSPENSION:BOOL`
- `HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES:BOOL`
- `HPX_WITH_THREAD_CUMULATIVE_COUNTS:BOOL`
- `HPX_WITH_THREAD_IDLE_RATES:BOOL`
- `HPX_WITH_THREAD_LOCAL_STORAGE:BOOL`
- `HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF:BOOL`
- `HPX_WITH_THREAD_QUEUE_WAITTIME:BOOL`
- `HPX_WITH_THREAD_STACK_MMAP:BOOL`
- `HPX_WITH_THREAD_STEALING_COUNTS:BOOL`
- `HPX_WITH_THREAD_TARGET_ADDRESS:BOOL`
- `HPX_WITH_TIMER_POOL:BOOL`

**HPX\_COROUTINES\_WITH\_SWAP\_CONTEXT\_EMULATION:BOOL**

Emulate SwapContext API for coroutines (Windows only, default: OFF)

**HPX\_WITH\_COROUTINE\_COUNTERS:BOOL**

Enable keeping track of coroutine creation and rebinding counts (default: OFF)

**HPX\_WITH\_IO\_POOL:BOOL**

Disable internal IO thread pool, do not change if not absolutely necessary (default: ON)

**HPX\_WITH\_MAX\_CPU\_COUNT:STRING**

HPX applications will not use more than this number of OS-Threads (empty string means dynamic) (default: "")

**HPX\_WITH\_MAX\_NUMA\_DOMAIN\_COUNT:STRING**

HPX applications will not run on machines with more NUMA domains (default: 8)

**HPX\_WITH\_SCHEDULER\_LOCAL\_STORAGE:BOOL**

Enable scheduler local storage for all HPX schedulers (default: OFF)

**HPX\_WITH\_SPINLOCK\_DEADLOCK\_DETECTION:BOOL**

Enable spinlock deadlock detection (default: OFF)

**HPX\_WITH\_SPINLOCK\_POOL\_NUM:STRING**

Number of elements a spinlock pool manages (default: 128)

**HPX\_WITH\_STACKTRACES:BOOL**

Attach backtraces to HPX exceptions (default: ON)

**HPX\_WITH\_STACKTRACES\_DEMANGLE\_SYMBOLS:BOOL**

Thread stack back trace symbols will be demangled (default: ON)

**HPX\_WITH\_STACKTRACES\_STATIC\_SYMBOLS:BOOL**

Thread stack back trace will resolve static symbols (default: OFF)

**HPX\_WITH\_THREAD\_BACKTRACE\_DEPTH:STRING**

Thread stack back trace depth being captured (default: 20)

**HPX\_WITH\_THREAD\_BACKTRACE\_ON\_SUSPENSION:BOOL**

Enable thread stack back trace being captured on suspension (default: OFF)

**HPX\_WITH\_THREAD\_CREATION\_AND\_CLEANUP\_RATES:BOOL**

Enable measuring thread creation and cleanup times (default: OFF)

**HPX\_WITH\_THREAD\_CUMULATIVE\_COUNTS:BOOL**

Enable keeping track of cumulative thread counts in the schedulers (default: ON)

**HPX\_WITH\_THREAD\_IDLE\_RATES:BOOL**

Enable measuring the percentage of overhead times spent in the scheduler (default: OFF)

**HPX\_WITH\_THREAD\_LOCAL\_STORAGE:BOOL**

Enable thread local storage for all HPX threads (default: OFF)

**HPX\_WITH\_THREAD\_MANAGER\_IDLE\_BACKOFF:BOOL**

HPX scheduler threads do exponential backoff on idle queues (default: ON)

**HPX\_WITH\_THREAD\_QUEUE\_WAITTIME:BOOL**

Enable collecting queue wait times for threads (default: OFF)

**HPX\_WITH\_THREAD\_STACK\_MMAP:BOOL**

Use mmap for stack allocation on appropriate platforms

**HPX\_WITH\_THREAD\_STEALING\_COUNTS:BOOL**

Enable keeping track of counts of thread stealing incidents in the schedulers (default: OFF)

**HPX\_WITH\_THREAD\_TARGET\_ADDRESS:BOOL**

Enable storing target address in thread for NUMA awareness (default: OFF)

**HPX\_WITH\_TIMER\_POOL:BOOL**

Disable internal timer thread pool, do not change if not absolutely necessary (default: ON)

## AGAS options

- *HPX\_WITH\_AGAS\_DUMP\_REFCNT\_ENTRIES:BOOL*

**HPX\_WITH\_AGAS\_DUMP\_REFCNT\_ENTRIES:BOOL**

Enable dumps of the AGAS refcnt tables to logs (default: OFF)

## Parcelport options

- *HPX\_WITH\_NETWORKING:BOOL*
- *HPX\_WITH\_PARCELPORT\_ACTION\_COUNTERS:BOOL*
- *HPX\_WITH\_PARCELPORT\_COUNTERS:BOOL*
- *HPX\_WITH\_PARCELPORT\_LCI:BOOL*
- *HPX\_WITH\_PARCELPORT\_LIBFABRIC:BOOL*
- *HPX\_WITH\_PARCELPORT\_MPI:BOOL*
- *HPX\_WITH\_PARCELPORT\_TCP:BOOL*
- *HPX\_WITH\_PARCEL\_PROFILING:BOOL*

**HPX\_WITH\_NETWORKING:BOOL**

Enable support for networking and multi-node runs (default: ON)

**HPX\_WITH\_PARCELPORT\_ACTION\_COUNTERS:BOOL**

Enable performance counters reporting parcelport statistics on a per-action basis.

**HPX\_WITH\_PARCELPORT\_COUNTERS:BOOL**

Enable performance counters reporting parcelport statistics.

**HPX\_WITH\_PARCELPORT\_LCI:BOOL**

Enable the LCI based parcelport.

**HPX\_WITH\_PARCELPORT\_LIBFABRIC:BOOL**

Enable the libfabric based parcelport. This is currently an experimental feature

**HPX\_WITH\_PARCELPORT\_MPI:BOOL**

Enable the MPI based parcelport.

**HPX\_WITH\_PARCELPORT\_TCP:BOOL**

Enable the TCP based parcelport.

**HPX\_WITH\_PARCEL\_PROFILING:BOOL**

Enable profiling data for parcels

## Profiling options

- *HPX\_WITH\_APEX:BOOL*
- *HPX\_WITH\_ITTNOTIFY:BOOL*
- *HPX\_WITH\_PAPI:BOOL*

**HPX\_WITH\_APEX:BOOL**

Enable APEX instrumentation support.

**HPX\_WITH\_ITTNOTIFY:BOOL**

Enable Amplifier (ITT) instrumentation support.

**HPX\_WITH\_PAPI:BOOL**

Enable the PAPI based performance counter.

## Debugging options

- *HPX\_WITH\_ATTACH\_DEBUGGER\_ON\_TEST\_FAILURE:BOOL*
- *HPX\_WITH\_PARALLEL\_TESTS\_BIND\_NONE:BOOL*
- *HPX\_WITH\_SANITIZERS:BOOL*
- *HPX\_WITH\_TESTS\_DEBUG\_LOG:BOOL*
- *HPX\_WITH\_TESTS\_DEBUG\_LOG\_DESTINATION:STRING*
- *HPX\_WITH\_TESTS\_MAX\_THREADS\_PER\_LOCALITY:STRING*
- *HPX\_WITH\_THREAD\_DEBUG\_INFO:BOOL*
- *HPX\_WITH\_THREAD\_DESCRIPTION\_FULL:BOOL*
- *HPX\_WITH\_THREAD\_GUARD\_PAGE:BOOL*
- *HPX\_WITH\_VALGRIND:BOOL*
- *HPX\_WITH\_VERIFY\_LOCKS:BOOL*

- `HPX_WITH_VERIFY_LOCKS_BACKTRACE:BOOL`

**`HPX_WITH_ATTACH_DEBUGGER_ON_TEST_FAILURE:BOOL`**

Break the debugger if a test has failed (default: OFF)

**`HPX_WITH_PARALLEL_TESTS_BIND_NONE:BOOL`**

Pass `-hpx:bind=none` to tests that may run in parallel (cmake -j flag) (default: OFF)

**`HPX_WITH_SANITIZERS:BOOL`**

Configure with sanitizer instrumentation support.

**`HPX_WITH_TESTS_DEBUG_LOG:BOOL`**

Turn on debug logs (`-hpx:debug-hpx-log`) for tests (default: OFF)

**`HPX_WITH_TESTS_DEBUG_LOG_DESTINATION:STRING`**

Destination for test debug logs (default: cout)

**`HPX_WITH_TESTS_MAX_THREADS_PER_LOCALITY:STRING`**

Maximum number of threads to use for tests (default: 0, use the number of threads specified by the test)

**`HPX_WITH_THREAD_DEBUG_INFO:BOOL`**

Enable thread debugging information (default: OFF, implicitly enabled in debug builds)

**`HPX_WITH_THREAD_DESCRIPTION_FULL:BOOL`**

Use function address for thread description (default: OFF)

**`HPX_WITH_THREAD_GUARD_PAGE:BOOL`**

Enable thread guard page (default: ON)

**`HPX_WITH_VALGRIND:BOOL`**

Enable Valgrind instrumentation support.

**`HPX_WITH_VERIFY_LOCKS:BOOL`**

Enable lock verification code (default: OFF, enabled in debug builds)

**`HPX_WITH_VERIFY_LOCKS_BACKTRACE:BOOL`**

Enable thread stack back trace being captured on lock registration (to be used in combination with `HPX_WITH_VERIFY_LOCKS=ON`, default: OFF)

## Modules options

- `HPX_DATASTRUCTURES_WITH_ADAPT_STD_TUPLE:BOOL`
- `HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY:BOOL`
- `HPX_ITERATOR_SUPPORT_WITH_BOOST_ITERATOR_TRAVERSAL_TAG_COMPATIBILITY:BOOL`
- `HPX_SERIALIZATION_WITH_ALLOW_CONST_TUPLE_MEMBERS:BOOL`
- `HPX_SERIALIZATION_WITH_ALLOW_RAW_POINTER_SERIALIZATION:BOOL`
- `HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE:BOOL`
- `HPX_SERIALIZATION_WITH_BOOST_TYPES:BOOL`
- `HPX_SERIALIZATION_WITH_SUPPORTS_ENDIANESS:BOOL`
- `HPX_TOPOLOGY_WITH_ADDITIONAL_HWLOC_TESTING:BOOL`
- `HPX_WITH_POWER_COUNTER:BOOL`

**HPX\_DATASTRUCTURES\_WITH\_ADAPT\_STD\_TUPLE:BOOL**

Enable compatibility of hpx::tuple with std::tuple. (default: ON)

**HPX\_FILESYSTEM\_WITH\_BOOST\_FILESYSTEM\_COMPATIBILITY:BOOL**

Enable Boost.FileSystem compatibility. (default: OFF)

**HPX\_ITERATOR\_SUPPORT\_WITH\_BOOST\_ITERATOR\_TRAVERSAL\_TAG\_COMPATIBILITY:BOOL**

Enable Boost.Iterator traversal tag compatibility. (default: OFF)

**HPX\_SERIALIZATION\_WITH\_ALLOW\_CONST\_TUPLE\_MEMBERS:BOOL**

Enable serializing std::tuple with const members. (default: OFF)

**HPX\_SERIALIZATION\_WITH\_ALLOW\_RAW\_POINTER\_SERIALIZATION:BOOL**

Enable serializing raw pointers. (default: OFF)

**HPX\_SERIALIZATION\_WITH\_ALL\_TYPES\_ARE\_BITWISE\_SERIALIZABLE:BOOL**

Assume all types are bitwise serializable. (default: OFF)

**HPX\_SERIALIZATION\_WITH\_BOOST\_TYPES:BOOL**

Enable serialization of certain Boost types. (default: OFF)

**HPX\_SERIALIZATION\_WITH\_SUPPORTS\_ENDIANESS:BOOL**

Support endian conversion on inout and output archives. (default: OFF)

**HPX\_TOPOLOGY\_WITH\_ADDITIONAL\_HWLOC\_TESTING:BOOL**

Enable HWLOC filtering that makes it report no cores, this is purely an option supporting better testing - do not enable under normal circumstances. (default: OFF)

**HPX\_WITH\_POWER\_COUNTER:BOOL**

Enable use of performance counters based on pwr library (default: OFF)

## Additional tools and libraries used by HPX

Here is a list of additional libraries and tools that are either optionally supported by the build system or are optionally required for certain examples or tests. These libraries and tools can be detected by the *HPX* build system.

Each of the tools or libraries listed here will be automatically detected if they are installed in some standard location. If a tool or library is installed in a different location, you can specify its base directory by appending \_ROOT to the variable name as listed below. For instance, to configure a custom directory for BOOST, specify BOOST\_ROOT=/custom/boost/root.

**BOOST\_ROOT:PATH**

Specifies where to look for the Boost installation to be used for compiling *HPX*. Set this if CMake is not able to locate a suitable version of Boost. The directory specified here can be either the root of an installed Boost distribution or the directory where you unpacked and built Boost without installing it (with staged libraries).

**HWLOC\_ROOT:PATH**

Specifies where to look for the hwloc library. Set this if CMake is not able to locate a suitable version of hwloc. Hwloc provides platform- independent support for extracting information about the used hardware architecture (number of cores, number of NUMA domains, hyperthreading, etc.). *HPX* utilizes this information if available.

**PAPI\_ROOT:PATH**

Specifies where to look for the PAPI library. The PAPI library is needed to compile a special component exposing PAPI hardware events and counters as *HPX* performance counters. This is not available on the Windows platform.

**AMPLIFIER\_ROOT:PATH**

Specifies where to look for one of the tools of the Intel Parallel Studio product, either Intel Amplifier or Intel Inspector. This should be set if the CMake variable HPX\_USE\_ITT\_NOTIFY is set to ON. Enabling ITT support in *HPX* will integrate any application with the mentioned Intel tools, which customizes the generated information for your application and improves the generated diagnostics.

In addition, some of the examples may need the following variables:

**HDF5\_ROOT:PATH**

Specifies where to look for the Hierarchical Data Format V5 (HDF5) include files and libraries.

### 2.3.5 Creating *HPX* projects

#### Using *HPX* with `pkg-config`

##### How to build *HPX* applications with `pkg-config`

After you are done installing *HPX*, you should be able to build the following program. It prints Hello World! on the *locality* you run it on.

```
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Copy the text of this program into a file called `hello_world.cpp`.

Now, in the directory where you put `hello_world.cpp`, issue the following commands (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building *HPX*):

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o hello_world hello_world.cpp \
`pkg-config --cflags --libs hpx_application`\ 
-lhpx_iostreams -DHPX_APPLICATION_NAME=hello_world
```

---

**Important:** When using `pkg-config` with *HPX*, the `pkg-config` flags must go after the `-o` flag.

---

**Note:** *HPX* libraries have different names in debug and release mode. If you want to link against a debug *HPX* library, you need to use the `_debug` suffix for the `pkg-config` name. That means instead of `hpx_application` or `hpx_component`, you will have to use `hpx_application_debug` or `hpx_component_debug`. Moreover, all referenced *HPX* components need to have an appended `d` suffix. For example, instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

---

---

**Important:** If the *HPX* libraries are in a path that is not found by the dynamic linker, you will need to add the path \$HPX\_LOCATION/lib to your linker search path (for example LD\_LIBRARY\_PATH on Linux).

---

To test the program, type:

```
$ ./hello_world
```

which should print Hello World! and exit.

## How to build *HPX* components with pkg-config

Let's try a more complex example involving an *HPX* component. An *HPX* component is a class that exposes *HPX* actions. *HPX* components are compiled into dynamically loaded modules called component libraries. Here's the source code:

### hello\_world\_component.cpp

```
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/iostream.hpp>
#include "hello_world_component.hpp"

#include <iostream>

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}} // namespace examples::server

HPX_REGISTER_COMPONENT_MODULE()

typedef hpx::components::component<examples::server::hello_world>
    hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world)

HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)
#endif
```

### hello\_world\_component.hpp

```
#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/components.hpp>
#include <hpx/include/lcos.hpp>
```

(continues on next page)

(continued from previous page)

```
#include <hpx/serialization.hpp>

#include <utility>

namespace examples { namespace server {
    struct HPX_COMPONENT_EXPORT hello_world
        : hpx::components::component_base<hello_world>
    {
        void invoke();
        HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke)
    };
}} // namespace examples::server

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)

namespace examples {
    struct hello_world
        : hpx::components::client_base<hello_world, server::hello_world>
    {
        typedef hpx::components::client_base<hello_world, server::hello_world>
            base_type;

        hello_world(hpx::future<hpx::id_type>&& f)
            : base_type(std::move(f))
        {}

        hello_world(hpx::id_type&& f)
            : base_type(std::move(f))
        {}

        void invoke()
        {
            hpx::async<server::hello_world::invoke_action>(*this->get_id())
                .get();
        }
    };
} // namespace examples

#endif
```

**hello\_world\_client.cpp**

```
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>

#include "hello_world_component.hpp"

int main()
```

(continues on next page)

(continued from previous page)

```
{
{
    // Create a single instance of the component on this locality.
    examples::hello_world client =
        hpx::new<examples::hello_world>(hpx::find_here());

    // Invoke the component's action, which will print "Hello World!".
    client.invoke();
}

return 0;
}
#endif
```

Copy the three source files above into three files (called `hello_world_component.cpp`, `hello_world_component.hpp` and `hello_world_client.cpp`, respectively).

Now, in the directory where you put the files, run the following command to build the component library. (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building *HPX*):

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o libhpx_hello_world.so hello_world_component.cpp \
`pkg-config --cflags --libs hpx_component` \
-lhpx_iostreams -DHPX_COMPONENT_NAME=hpx_hello_world
```

Now pick a directory in which to install your *HPX* component libraries. For this example, we'll choose a directory named `my_hpx_libs`:

```
$ mkdir ~/my_hpx_libs
$ mv libhpx_hello_world.so ~/my_hpx_libs
```

---

**Note:** *HPX* libraries have different names in debug and release mode. If you want to link against a debug *HPX* library, you need to use the `_debug` suffix for the `pkg-config` name. That means instead of `hpx_application` or `hpx_component` you will have to use `hpx_application_debug` or `hpx_component_debug`. Moreover, all referenced *HPX* components need to have a appended `d` suffix, e.g. instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

---

---

**Important:** If the *HPX* libraries are in a path that is not found by the dynamic linker. You need to add the path `$HPX_LOCATION/lib` to your linker search path (for example `LD_LIBRARY_PATH` on Linux).

---

Now, to build the application that uses this component (`hello_world_client.cpp`), we do:

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o hello_world_client hello_world_client.cpp \
` ` pkg-config --cflags --libs hpx_application` ` \
-L${HOME}/my_hpx_libs -lhpx_hello_world -lhpx_iostreams
```

---

**Important:** When using `pkg-config` with *HPX*, the `pkg-config` flags must go after the `-o` flag.

---

Finally, you'll need to set your LD\_LIBRARY\_PATH before you can run the program. To run the program, type:

```
$ export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:$HOME/my_hpx_libs"
$ ./hello_world_client
```

which should print Hello HPX World! and exit.

## Using HPX with CMake-based projects

In addition to the pkg-config support discussed on the previous pages, *HPX* comes with full CMake support. In order to integrate *HPX* into existing or new CMakeLists.txt, you can leverage the `find_package`<sup>38</sup> command integrated into CMake. Following, is a Hello World component example using CMake.

Let's revisit what we have. We have three files that compose our example application:

- `hello_world_component.hpp`
- `hello_world_component.cpp`
- `hello_world_client.hpp`

The basic structure to include *HPX* into your CMakeLists.txt is shown here:

```
# Require a recent version of cmake
cmake_minimum_required(VERSION 3.18 FATAL_ERROR)

# This project is C++ based.
project(your_app CXX)

# Instruct cmake to find the HPX settings
find_package(HPX)
```

In order to have CMake find *HPX*, it needs to be told where to look for the `HPXConfig.cmake` file that is generated when *HPX* is built or installed. It is used by `find_package(HPX)` to set up all the necessary macros needed to use *HPX* in your project. The ways to achieve this are:

- Set the `HPX_DIR` CMake variable to point to the directory containing the `HPXConfig.cmake` script on the command line when you invoke CMake:

```
$ cmake -DHPX_DIR=$HPX_LOCATION/lib/cmake/HPX ...
```

where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used when building/configuring *HPX*.

- Set the `CMAKE_PREFIX_PATH` variable to the root directory of your *HPX* build or install location on the command line when you invoke CMake:

```
$ cmake -DCMAKE_PREFIX_PATH=$HPX_LOCATION ...
```

The difference between `CMAKE_PREFIX_PATH` and `HPX_DIR` is that CMake will add common postfixes, such as `lib/cmake/<project>`, to the `CMAKE_PREFIX_PATH` and search in these locations too. Note that if your project uses *HPX* as well as other CMake-managed projects, the paths to the locations of these multiple projects may be concatenated in the `CMAKE_PREFIX_PATH`.

- The variables above may be set in the CMake GUI or curses `ccmake` interface instead of the command line.

<sup>38</sup> [https://www.cmake.org/cmake/help/latest/command/find\\_package.html](https://www.cmake.org/cmake/help/latest/command/find_package.html)

Additionally, if you wish to require *HPX* for your project, replace the `find_package(HPX)` line with `find_package(HPX REQUIRED)`.

You can check if *HPX* was successfully found with the `HPX_FOUND` CMake variable.

## Using CMake targets

The recommended way of setting up your targets to use *HPX* is to link to the `HPX::hpx` CMake target:

```
target_link_libraries(hello_world_component PUBLIC HPX::hpx)
```

This requires that you have already created the target like this:

```
add_library(hello_world_component SHARED hello_world_component.cpp)
target_include_directories(hello_world_component PUBLIC ${CMAKE_CURRENT_SOURCE_DIR})
```

When you link your library to the `HPX::hpx` CMake target, you will be able use *HPX* functionality in your library. To use `main()` as the implicit entry point in your application you must additionally link your application to the CMake target `HPX::wrap_main`. This target is automatically linked to executables if you are using the macros described below ([Using macros to create new targets](#)). See [Re-use the main\(\) function as the main HPX entry point](#) for more information on implicitly using `main()` as the entry point.

Creating a component requires setting two additional compile definitions:

```
target_compile_options(hello_world_component
    HPX_COMPONENT_NAME=hello_world
    HPX_COMPONENT_EXPORTS)
```

Instead of setting these definitions manually you may link to the `HPX::component` target, which sets `HPX_COMPONENT_NAME` to `hpx_<target_name>`, where `<target_name>` is the target name of your library. Note that these definitions should be `PRIVATE` to make sure these definitions are not propagated transitively to dependent targets.

In addition to making your library a component you can make it a plugin. To do so link to the `HPX::plugin` target. Similarly to `HPX::component` this will set `HPX_PLUGIN_NAME` to `hpx_<target_name>`. This definition should also be `PRIVATE`. Unlike regular shared libraries, plugins are loaded at runtime from certain directories and will not be found without additional configuration. Plugins should be installed into a directory containing only plugins. For example, the plugins created by *HPX* itself are installed into the `hpx` subdirectory in the library install directory (typically `lib` or `lib64`). When using the `HPX::plugin` target you need to install your plugins into an appropriate directory. You may also want to set the location of your plugin in the build directory with the `*_OUTPUT_DIRECTORY*` CMake target properties to be able to load the plugins in the build directory. Once you've set the install or output directory of your plugin you need to tell your executable where to find it at runtime. You can do this either by setting the environment variable `HPX_COMPONENT_PATHS` or the ini setting `hpx.component_paths` (see [--hpx:ini](#)) to the directory containing your plugin.

## Using macros to create new targets

In addition to the targets described above, *HPX* provides convenience macros to hide optional boilerplate code that may be useful for your project. The link to the targets described above. We recommend that you use the targets directly whenever possible as they tend to compose better with other targets.

The macro for adding an *HPX* component is `add_hpx_component`. It can be used in your `CMakeLists.txt` file like this:

```
# build your application using HPX
add_hpx_component(hello_world
    SOURCES hello_world_component.cpp
    HEADERS hello_world_component.hpp
    COMPONENT_DEPENDENCIES iostreams)
```

---

**Note:** `add_hpx_component` adds a `_component` suffix to the target name. In the example above, a `hello_world_component` target will be created.

---

The available options to `add_hpx_component` are:

- `SOURCES`: The source files for that component
- `HEADERS`: The header files for that component
- `DEPENDENCIES`: Other libraries or targets this component depends on
- `COMPONENT_DEPENDENCIES`: The components this component depends on
- `PLUGIN`: Treats this component as a plugin-able library
- `COMPILE_FLAGS`: Additional compiler flags
- `LINK_FLAGS`: Additional linker flags
- `FOLDER`: Adds the headers and source files to this Source Group folder
- `EXCLUDE_FROM_ALL`: Do not build this component as part of the `all` target

After adding the component, the way you add the executable is as follows:

```
# build your application using HPX
add_hpx_executable(hello_world
    SOURCES hello_world_client.cpp
    COMPONENT_DEPENDENCIES hello_world)
```

---

**Note:** `add_hpx_executable` automatically adds a `_component` suffix to dependencies specified in `COMPONENT_DEPENDENCIES`, meaning you can directly use the name given when adding a component using `add_hpx_component`.

---

When you configure your application, all you need to do is set the `HPX_DIR` variable to point to the installation of *HPX*.

---

**Note:** All library targets built with *HPX* are exported and readily available to be used as arguments to `target_link_libraries`<sup>39</sup> in your targets. The *HPX* include directories are available with the `HPX_INCLUDE_DIRS` CMake variable.

---

<sup>39</sup> [https://www.cmake.org/cmake/help/latest/command/target\\_link\\_libraries.html](https://www.cmake.org/cmake/help/latest/command/target_link_libraries.html)

## Using the *HPX* compiler wrapper `hpxcxx`

The `hpxcxx` compiler wrapper helps to compile a *HPX* component, application, or object file, based on the arguments passed to it.

```
$ hpxcxx [--exe=<APPLICATION_NAME> | --comp=<COMPONENT_NAME> | -c] FLAGS FILES
```

The `hpxcxx` command **requires** that either an application or a component is built or `-c` flag is specified. If the build is against a debug build, the `-g` is to be specified while building.

### Optional FLAGS

- `-l <LIBRARY> | -L<LIBRARY>`: Links `<LIBRARY>` to the build
- `-g`: Specifies that the application or component build is against a debug build
- `-rd`: Sets `release-with-debug-info` option
- `-mr`: Sets `minsize-release` option

All other flags (like `-o OUTPUT_FILE`) are directly passed to the underlying C++ compiler.

## Using macros to set up existing targets to use *HPX*

In addition to the `add_hpx_component` and `add_hpx_executable`, you can use the `hpx_setup_target` macro to have an already existing target to be used with the *HPX* libraries:

```
hpx_setup_target(target)
```

Optional parameters are:

- `EXPORT`: Adds it to the CMake export list `HPXTargets`
- `INSTALL`: Generates an install rule for the target
- `PLUGIN`: Treats this component as a plugin-able library
- `TYPE`: The type can be: `EXECUTABLE`, `LIBRARY` or `COMPONENT`
- `DEPENDENCIES`: Other libraries or targets this component depends on
- `COMPONENT_DEPENDENCIES`: The components this component depends on
- `COMPILE_FLAGS`: Additional compiler flags
- `LINK_FLAGS`: Additional linker flags

If you do not use CMake, you can still build against *HPX*, but you should refer to the section on *How to build HPX components with pkg-config*.

---

**Note:** Since *HPX* relies on dynamic libraries, the dynamic linker needs to know where to look for them. If *HPX* isn't installed into a path that is configured as a linker search path, external projects need to either set `RPATH` or adapt `LD_LIBRARY_PATH` to point to where the *HPX* libraries reside. In order to set `RPATHs`, you can include `HPX_SetFullRPATH` in your project after all libraries you want to link against have been added. Please also consult the CMake documentation [here<sup>40</sup>](#).

---

<sup>40</sup> <https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/RPATH-handling>

## Using HPX with Makefile

A basic project building with *HPX* is through creating makefiles. The process of creating one can get complex depending upon the use of cmake parameter `HPX_WITH_HPX_MAIN` (which defaults to ON).

### How to build *HPX* applications with makefile

If *HPX* is installed correctly, you should be able to build and run a simple Hello World program. It prints Hello World! on the *locality* you run it on.

```
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Copy the content of this program into a file called `hello_world.cpp`.

Now, in the directory where you put `hello_world.cpp`, create a Makefile. Add the following code:

```
CXX=(CXX) # Add your favourite compiler here or let makefile choose default.

CXXFLAGS=-O3 -std=c++17

BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=$(HPX_ROOT)/include $(BOOST_ROOT)/include $(HWLOC_ROOT)/include

LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(HPX_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/
↳ libhpx.so $(BOOST_ROOT)/lib/libboost_atomic-mt.so $(BOOST_ROOT)/lib/libboost_
↳ filesystem-mt.so $(BOOST_ROOT)/lib/libboost_program_options-mt.so $(BOOST_ROOT)/lib/
↳ libboost_regex-mt.so $(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread $(TCMALLOC_
↳ ROOT)/libtcmalloc_minimal.so $(HWLOC_ROOT)/libhwloc.so -ldl -lrt

LINK_FLAGS=$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main # should be left empty for HPX_
↳ WITH_HPX_MAIN=OFF

hello_world: hello_world.o
    $(CXX) $(CXXFLAGS) -o hello_world hello_world.o $(LIBRARY_DIRECTIVES) $(LINK_FLAGS)

hello_world.o:
    $(CXX) $(CXXFLAGS) -c -o hello_world.o hello_world.cpp $(INCLUDE_DIRECTIVES)
```

---

**Important:** `LINK_FLAGS` should be left empty if `HPX_WITH_HPX_MAIN` is set to OFF. Boost in the above example

is build with --layout=tagged. Actual Boost flags may vary on your build of Boost.

---

To build the program, type:

```
$ make
```

A successful build should result in hello\_world binary. To test, type:

```
$ ./hello_world
```

## How to build HPX components with makefile

Let's try a more complex example involving an *HPX* component. An *HPX* component is a class that exposes *HPX* actions. *HPX* components are compiled into dynamically-loaded modules called component libraries. Here's the source code:

### hello\_world\_component.cpp

```
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/iostream.hpp>
#include "hello_world_component.hpp"

#include <iostream>

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}} // namespace examples::server

HDX_REGISTER_COMPONENT_MODULE()

typedef hpx::components::component<examples::server::hello_world>
    hello_world_type;

HDX_REGISTER_COMPONENT(hello_world_type, hello_world)

HDX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)
#endif
```

### hello\_world\_component.hpp

```
#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/components.hpp>
```

(continues on next page)

(continued from previous page)

```
#include <hpx/include/lcos.hpp>
#include <hpx/serialization.hpp>

#include <utility>

namespace examples { namespace server {
    struct HPX_COMPONENT_EXPORT hello_world
        : hpx::components::component_base<hello_world>
    {
        void invoke();
        HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke)
    };
}} // namespace examples::server

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)

namespace examples {
    struct hello_world
        : hpx::components::client_base<hello_world, server::hello_world>
    {
        typedef hpx::components::client_base<hello_world, server::hello_world>
            base_type;

        hello_world(hpx::future<hpx::id_type>&& f)
            : base_type(std::move(f))
        {}

        hello_world(hpx::id_type&& f)
            : base_type(std::move(f))
        {}

        void invoke()
        {
            hpx::async<server::hello_world::invoke_action>(<this>->get_id())
                .get();
        }
    };
} // namespace examples

#endif
```

**hello\_world\_client.cpp**

```
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>

#include "hello_world_component.hpp"
```

(continues on next page)

(continued from previous page)

```

int main()
{
    {
        // Create a single instance of the component on this locality.
        examples::hello_world client =
            hpx::new_<examples::hello_world>(hpx::find_here());

        // Invoke the component's action, which will print "Hello World!".
        client.invoke();
    }

    return 0;
}
#endif

```

Now, in the directory, create a Makefile. Add the following code:

```

CXX=(CXX) # Add your favourite compiler here or let makefile choose default.

CXXFLAGS=-O3 -std=c++17

BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=$(HPX_ROOT)/include $(BOOST_ROOT)/include $(HWLOC_ROOT)/include

LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(HPX_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/
    libhpx.so $(BOOST_ROOT)/lib/libboost_atomic-mt.so $(BOOST_ROOT)/lib/libboost_
    filesystem-mt.so $(BOOST_ROOT)/lib/libboost_program_options-mt.so $(BOOST_ROOT)/lib/
    libboost_regex-mt.so $(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread $(TCMALLOC_
    ROOT)/libtcmalloc_minimal.so $(HWLOC_ROOT)/libhwloc.so -ldl -lrt

LINK_FLAGS=$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main # should be left empty for HPX_
    WITH_HPX_MAIN=OFF

hello_world_client: libhpx_hello_world hello_world_client.o
    $(CXX) $(CXXFLAGS) -o hello_world_client $(LIBRARY_DIRECTIVES) libhpx_hello_world
    $(LINK_FLAGS)

hello_world_client.o: hello_world_client.cpp
    $(CXX) $(CXXFLAGS) -o hello_world_client.o hello_world_client.cpp $(INCLUDE_DIRECTIVES)

libhpx_hello_world: hello_world_component.o
    $(CXX) $(CXXFLAGS) -o libhpx_hello_world hello_world_component.o $(LIBRARY_DIRECTIVES)

hello_world_component.o: hello_world_component.cpp
    $(CXX) $(CXXFLAGS) -c -o hello_world_component.o hello_world_component.cpp $(INCLUDE_
    DIRECTIVES)

```

To build the program, type:

```
$ make
```

A successful build should result in hello\_world binary. To test, type:

```
$ ./hello_world
```

---

**Note:** Due to high variations in CMake flags and library dependencies, it is recommended to build *HPX* applications and components with pkg-config or CMakeLists.txt. Writing Makefile may result in broken builds if due care is not taken. pkg-config files and CMake systems are configured with CMake build of *HPX*. Hence, they are stable when used together and provide better support overall.

---

### 2.3.6 Starting the *HPX* runtime

In order to write an application that uses services from the *HPX* runtime system, you need to initialize the *HPX* library by inserting certain calls into the code of your application. Depending on your use case, this can be done in 3 different ways:

- *Minimally invasive*: Re-use the main() function as the main *HPX* entry point.
- *Balanced use case*: Supply your own main *HPX* entry point while blocking the main thread.
- *Most flexibility*: Supply your own main *HPX* entry point while avoiding blocking the main thread.
- *Suspend and resume*: As above but suspend and resume the *HPX* runtime to allow for other runtimes to be used.

#### Re-use the main() function as the main *HPX* entry point

This method is the least intrusive to your code. However, it provides you with the smallest flexibility in terms of initializing the *HPX* runtime system. The following code snippet shows what a minimal *HPX* application using this technique looks like:

```
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[])
{
    return 0;
}
```

The only change to your code you have to make is to include the file hpx/hpx\_main.hpp. In this case the function main() will be invoked as the first *HPX* thread of the application. The runtime system will be initialized behind the scenes before the function main() is executed and will automatically stop after main() has returned. For this method to work you must link your application to the CMake target HPX::wrap\_main. This is done automatically if you are using the provided macros ([Using macros to create new targets](#)) to set up your application, but must be done explicitly if you are using targets directly ([Using CMake targets](#)). All *HPX* API functions can be used from within the main() function now.

---

**Note:** The function main() does not need to expect receiving argc and argv as shown above, but could expose the signature int main(). This is consistent with the usually allowed prototypes for the function main() in C++ applications.

---

All command line arguments specific to *HPX* will still be processed by the *HPX* runtime system as usual. However, those command line options will be removed from the list of values passed to `argc/argv` of the function `main()`. The list of values passed to `main()` will hold only the commandline options that are not recognized by the *HPX* runtime system (see the section [HPX Command Line Options](#) for more details on what options are recognized by *HPX*).

---

**Note:** In this mode all one-letter shortcuts that are normally available on the *HPX* command line are disabled (such as `-t` or `-l` see [HPX Command Line Options](#)). This is done to minimize any possible interaction between the command line options recognized by the *HPX* runtime system and any command line options defined by the application.

---

The value returned from the function `main()` as shown above will be returned to the operating system as usual.

---

**Important:** To achieve this seamless integration, the header file `hpx/hpx_main.hpp` defines a macro:

```
#define main hpx_startup::user_main
```

---

which could result in unexpected behavior.

---

**Important:** To achieve this seamless integration, we use different implementations for different operating systems. In case of Linux or macOS, the code present in `hpx_wrap.cpp` is put into action. We hook into the system function in case of Linux and provide alternate entry point in case of macOS. For other operating systems we rely on a macro:

```
#define main hpx_startup::user_main
```

---

provided in the header file `hpx/hpx_main.hpp`. This implementation can result in unexpected behavior.

---

**Caution:** We make use of an *override* variable `include_libhpx_wrap` in the header file `hpx/hpx_main.hpp` to swiftly choose the function call stack at runtime. Therefore, the header file should *only* be included in the main executable. Including it in the components will result in multiple definition of the variable.

### Supply your own main *HPX* entry point while blocking the main thread

With this method you need to provide an explicit main-thread function named `hpx_main` at global scope. This function will be invoked as the main entry point of your *HPX* application on the console [locality](#) only (this function will be invoked as the first *HPX* thread of your application). All *HPX* API functions can be used from within this function.

The thread executing the function `hpx::init` will block waiting for the runtime system to exit. The value returned from `hpx_main` will be returned from `hpx::init` after the runtime system has stopped.

The function `hpx::finalize` has to be called on one of the *HPX* localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking *HPX* has the advantage of the user being able to decide which version of `hpx::init` to call. This allows to pass additional configuration parameters while initializing the *HPX* runtime system.

```
#include <hpx/hpx_init.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
```

(continues on next page)

(continued from previous page)

```

    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main as the first HPX thread, and
    // wait for hpx::finalize being called.
    return hpx::init(argc, argv);
}

```

**Note:** The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:

```

int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);

```

This is consistent with (and extends) the usually allowed prototypes for the function `main()` in C++ applications.

The header file to include for this method of using *HPX* is `hpx/hpx_init.hpp`.

There are many additional overloads of `hpx::init` available, such as the ability to provide your own entry-point function instead of `hpx_main`. Please refer to the function documentation for more details (see: `hpx/hpx_init.hpp`).

### Supply your own main *HPX* entry point while avoiding blocking the main thread

With this method you need to provide an explicit main thread function named `hpx_main` at global scope. This function will be invoked as the main entry point of your *HPX* application on the console *locality* only (this function will be invoked as the first *HPX* thread of your application). All *HPX* API functions can be used from within this function.

The thread executing the function `hpx::start` will *not* block waiting for the runtime system to exit, but will return immediately. The function `hpx::finalize` has to be called on one of the *HPX* localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking *HPX* is useful for applications where the main thread is used for special operations, such as GUIs. The function `hpx::stop` can be used to wait for the *HPX* runtime system to exit and should at least be used as the last function called in `main()`. The value returned from `hpx_main` will be returned from `hpx::stop` after the runtime system has stopped.

```

#include <hpx/hpx_start.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main.
    hpx::start(argc, argv);
}

```

(continues on next page)

(continued from previous page)

```
// ...Execute other code here...

// Wait for hpx::finalize being called.
return hpx::stop();
}
```

**Note:** The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:

```
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```

This is consistent with (and extends) the usually allowed prototypes for the function `main()` in C++ applications.

The header file to include for this method of using *HPX* is `hpx/hpx_start.hpp`.

There are many additional overloads of `hpx::start` available, such as the option for users to provide their own entry point function instead of `hpx_main`. Please refer to the function documentation for more details (see: `hpx/hpx_start.hpp`).

### Suspending and resuming the *HPX* runtime

In some applications it is required to combine *HPX* with other runtimes. To support this use case, *HPX* provides two functions: `hpx::suspend` and `hpx::resume`. `hpx::suspend` is a blocking call which will wait for all scheduled tasks to finish executing and then put the thread pool OS threads to sleep. `hpx::resume` simply wakes up the sleeping threads so that they are ready to accept new work. `hpx::suspend` and `hpx::resume` can be found in the header `hpx/hpx_suspend.hpp`.

```
#include <hpx/hpx_start.hpp>
#include <hpx/hpx_suspend.hpp>

int main(int argc, char* argv[])
{
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule a function on the HPX runtime
    hpx::apply(&my_function, ...);

    // Wait for all tasks to finish, and suspend the HPX runtime
    hpx::suspend();

    // Execute non-HPX code here

    // Resume the HPX runtime
    hpx::resume();

    // Schedule more work on the HPX runtime
}
```

(continues on next page)

(continued from previous page)

```
// hpx::finalize has to be called from the HPX runtime before hpx::stop
hpx::apply([]() { hpx::finalize(); });
return hpx::stop();
}
```

**Note:** `hpx::suspend` does not wait for `hpx::finalize` to be called. Only call `hpx::finalize` when you wish to fully stop the *HPX* runtime.

**Warning:**

`hpx::suspend` only waits for local tasks, i.e. tasks on the current locality, to finish executing. When using `hpx::suspend` in a multi-locality scenario the user is responsible for ensuring that any work required from other localities has also finished.

*HPX* also supports suspending individual thread pools and threads. For details on how to do that, see the documentation for `hpx::threads::thread_pool_base`.

### Automatically suspending worker threads

The previous method guarantees that the worker threads are suspended when you ask for it and that they stay suspended. An alternative way to achieve the same effect is to tweak how quickly *HPX* suspends its worker threads when they run out of work. The following configuration values make sure that *HPX* idles very quickly:

```
hpx.max_idle_backoff_time = 1000
hpx.max_idle_loop_count = 0
```

They can be set on the command line using `--hpx:ini=hpx.max_idle_backoff_time=1000` and `--hpx:ini=hpx.max_idle_loop_count=0`. See [Launching and configuring HPX applications](#) for more details on how to set configuration parameters.

After setting idling parameters the previous example could now be written like this instead:

```
#include <hpx/hpx_start.hpp>

int main(int argc, char* argv[])
{
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule some functions on the HPX runtime
    // NOTE: run_as_hpx_thread blocks until completion.
    hpx::run_as_hpx_thread(&my_function, ...);
    hpx::run_as_hpx_thread(&my_other_function, ...);

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::apply([]() { hpx::finalize(); });
    return hpx::stop();
}
```

In this example each call to `hpx::run_as_hpx_thread` acts as a “parallel region”.

### Working of `hpx_main.hpp`

In order to initialize *HPX* from `main()`, we make use of linker tricks.

It is implemented differently for different operating systems. The method of implementation is as follows:

- *Linux*: Using linker `--wrap` option.
- *Mac OSX*: Using the linker `-e` option.
- *Windows*: Using `#define main hpx_startup::user_main`

### Linux implementation

We make use of the Linux linker `ld`’s `--wrap` option to wrap the `main()` function. This way any calls to `main()` are redirected to our own implementation of `main`. It is here that we check for the existence of `hpx_main.hpp` by making use of a shadow variable `include_libhpx_wrap`. The value of this variable determines the function stack at runtime.

The implementation can be found in `libhpx_wrap.a`.

---

**Important:** It is necessary that `hpx_main.hpp` be not included more than once. Multiple inclusions can result in multiple definition of `include_libhpx_wrap`.

---

### Mac OSX implementation

Here we make use of yet another linker option `-e` to change the entry point to our custom entry function `initialize_main`. We initialize the *HPX* runtime system from this function and call `main` from the initialized system. We determine the function stack at runtime by making use of the shadow variable `include_libhpx_wrap`.

The implementation can be found in `libhpx_wrap.a`.

---

**Important:** It is necessary that `hpx_main.hpp` be not included more than once. Multiple inclusions can result in multiple definition of `include_libhpx_wrap`.

---

### Windows implementation

We make use of a macro `#define main hpx_startup::user_main` to take care of the initializations.

This implementation could result in unexpected behaviors.

## 2.3.7 Launching and configuring HPX applications

### Configuring HPX applications

All HPX applications can be configured using special command line options and/or using special configuration files. This section describes the available options, the configuration file format, and the algorithm used to locate possible predefined configuration files. Additionally, this section describes the defaults assumed if no external configuration information is supplied.

During startup any HPX application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal database holding all configuration properties. This database is used during the execution of the application to configure different aspects of the runtime system.

In addition to the ini files, any application can supply its own configuration files, which will be merged with the configuration database as well. Moreover, the user can specify additional configuration parameters on the command line when executing an application. The HPX runtime system will merge all command line configuration options (see the description of the `--hpx:ini`, `--hpx:config`, and `--hpx:app-config` command line options).

### The HPX ini file format

All HPX applications can be configured using a special file format that is similar to the well-known Windows INI file format<sup>41</sup>. This is a structured text format that allows users to group key/value pairs (properties) into sections. The basic element contained in an ini file is the property. Every property has a name and a value, delimited by an equal sign '='. The name appears to the left of the equal sign:

```
name=value
```

The value may contain equal signs as only the first '=' character is interpreted as the delimiter between name and value. Whitespace before the name, after the value and immediately before and after the delimiting equal sign is ignored. Whitespace inside the value is retained.

Properties may be grouped into arbitrarily named sections. The section name appears on a line by itself, in square brackets. All properties after the section declaration are associated with that section. There is no explicit “end of section” delimiter; sections end at the next section declaration or the end of the file:

```
[section]
```

In HPX sections can be nested. A nested section has a name composed of all section names it is embedded in. The section names are concatenated using a dot '.':

```
[outer_section.inner_section]
```

Here, `inner_section` is logically nested within `outer_section`.

It is possible to use the full section name concatenated with the property name to refer to a particular property. For example, in:

```
[a.b.c]
d = e
```

the property value of `d` can be referred to as `a.b.c.d=e`.

In HPX ini files can contain comments. Hash signs '#' at the beginning of a line indicate a comment. All characters starting with '#' until the end of the line are ignored.

<sup>41</sup> [https://en.wikipedia.org/wiki/INI\\_file](https://en.wikipedia.org/wiki/INI_file)

If a property with the same name is reused inside a section, the second occurrence of this property name will override the first occurrence (discard the first value). Duplicate sections simply merge their properties together, as if they occurred contiguously.

In *HPX* ini files a property value  `${FOO:default}` will use the environmental variable `FOO` to extract the actual value if it is set and `default` otherwise. No default has to be specified. Therefore,  `${FOO}` refers to the environmental variable `FOO`. If `FOO` is not set or empty, the overall expression will evaluate to an empty string. A property value  `${[section.key]:default}` refers to the value held by the property `section.key` if it exists and `default` otherwise. No default has to be specified. Therefore  `${[section.key]}` refers to the property `section.key`. If the property `section.key` is not set or empty, the overall expression will evaluate to an empty string.

---

**Note:** Any property  `${[section.key]:default}` is evaluated whenever it is queried and not when the configuration data is initialized. This allows for lazy evaluation and relaxes initialization order of different sections. The only exception are recursive property values, e.g., values referring to the very key they are associated with. Those property values are evaluated at initialization time to avoid infinite recursion.

---

### Built-in default configuration settings

During startup any *HPX* application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal data structure holding all configuration properties.

As a first step the internal configuration database is filled with a set of default configuration properties. Those settings are described on a section by section basis below.

---

**Note:** You can print the default configuration settings used for an executable by specifying the command line option `--hpx:dump-config`.

---

### The system configuration section

```
[system]
pid = <process-id>
prefix = <current prefix path of core HPX library>
executable = <current prefix path of executable>
```

Property	Description
<code>system.pid</code>	This is initialized to store the current OS-process id of the application instance.
<code>system.prefix</code>	This is initialized to the base directory <i>HPX</i> has been loaded from.
<code>system.executable_prefix</code>	This is initialized to the base directory the current executable has been loaded from.

## The `Hpx` configuration section

```
[hpx]
location = ${HPX_LOCATION:${[system.prefix]}}
component_path = ${[hpx.location]/lib/hpx:${[system.executable_prefix]/lib/hpx:${[system.
↳executable_prefix]}/../lib/hpx
master_ini_path = ${[hpx.location]/share/hpx-<version>:${[system.executable_prefix]/share/
↳hpx-<version>:${[system.executable_prefix]}/../share/hpx-<version>
ini_path = ${[hpx.master_ini_path]/ini
os_threads = 1
localities = 1
program_name =
cmd_line =
lock_detection = ${HPX_LOCK_DETECTION:0}
throw_on_held_lock = ${HPX_THROW_ON_HELD_LOCK:1}
minimal_deadlock_detection = <debug>
spinlock_deadlock_detection = <debug>
spinlock_deadlock_detection_limit = ${HPX_SPINLOCK_DEADLOCK_DETECTION_LIMIT:1000000}
max_background_threads = ${HPX_MAX_BACKGROUND_THREADS:${[hpx.os_threads]}}
max_idle_loop_count = ${HPX_MAX_IDLE_LOOP_COUNT:<hpx_idle_loop_count_max>}
max_busy_loop_count = ${HPX_MAX_BUSY_LOOP_COUNT:<hpx_busy_loop_count_max>}
max_idle_backoff_time = ${HPX_MAX_IDLE_BACKOFF_TIME:<hpx_idle_backoff_time_max>}
exception_verbosity = ${HPX_EXCEPTION_VERBOSITY:2}

[hpx.stacks]
small_size = ${HPX_SMALL_STACK_SIZE:<hpx_small_stack_size>}
medium_size = ${HPX_MEDIUM_STACK_SIZE:<hpx_medium_stack_size>}
large_size = ${HPX_LARGE_STACK_SIZE:<hpx_large_stack_size>}
huge_size = ${HPX_HUGE_STACK_SIZE:<hpx_huge_stack_size>}
use_guard_pages = ${HPX_THREAD_GUARD_PAGE:1}
```

Property	Description
hpx.location	This is initialized to the id of the <i>locality</i> this application instance is running on.
hpx.component_path	Duplicates are discarded. This property can refer to a list of directories separated by ':' (Linux, Android, and MacOS) or by ';' (Windows).
hpx.master_ini_paths	This is initialized to the list of default paths of the main hpx.ini configuration files. This property can refer to a list of directories separated by ':' (Linux, Android, and MacOS) or using ';' (Windows).
hpx.ini_path	This is initialized to the default path where <i>HPX</i> will look for more ini configuration files. This property can refer to a list of directories separated by ':' (Linux, Android, and MacOS) or using ';' (Windows).
hpx.os_threads	This setting reflects the number of OS threads used for running <i>HPX</i> threads. Defaults to number of detected cores (not hyperthreads/PUs).
hpx.localities	This setting reflects the number of localities the application is running on. Defaults to 1.
hpx.program_name	This setting reflects the program name of the application instance. Initialized from the command line <code>argv[0]</code> .
hpx.cmd_line	This setting reflects the actual command line used to launch this application instance.
hpx.lock_detection	This setting verifies that no locks are being held while a <i>HPX</i> thread is suspended. This setting is applicable only if <code>HPX_WITH_VERIFY_LOCKS</code> is set during configuration in CMake.
hpx.throw_on_held_locks	This setting causes an exception if during lock detection at least one lock is being held while a <i>HPX</i> thread is suspended. This setting is applicable only if <code>HPX_WITH_VERIFY_LOCKS</code> is set during configuration in CMake. This setting has no effect if <code>hpx.lock_detection=0</code> .
hpx.minimal_deadlock_detection_time	This setting enables support for minimal deadlock detection for <i>HPX</i> threads. By default this is set to 10ms (for Debug builds) or to 0 (for Release, RelWithDebInfo, RelMinSize builds). This setting is effective only if <code>HPX_WITH_THREAD_DEADLOCK_DETECTION</code> is set during configuration in CMake.
hpx.spinlock_deadlock_detection_limit	This setting verifies that spinlocks don't spin longer than specified using the <code>spinlock_deadlock_detection_limit</code> . This setting is applicable only if <code>HPX_WITH_SPINLOCK_DEADLOCK_DETECTION</code> is set during configuration in CMake. By default this is set to 1 (for Debug builds) or to 0 (for Release, RelWithDebInfo, RelMinSize builds).
hpx.spinlock_deadlock_detection_timeout	This setting specifies the upper limit of the allowed number of spins that spinlocks are allowed to perform before timing out. This setting is applicable only if <code>HPX_WITH_SPINLOCK_DEADLOCK_DETECTION</code> is set during configuration in CMake. By default this is set to 1000000.
hpx.max_background_threads	This setting defines the number of threads in the scheduler, which are used to execute background work. By default this is the same as the number of cores used for the scheduler.
hpx.max_idle_loops	By default this is defined by the preprocessor constant <code>HPX_IDLE_LOOP_COUNT_MAX</code> . This is an internal setting that you should change only if you know exactly what you are doing.
hpx.max_busy_loops	This setting defines the maximum value of the busy-loop counter in the scheduler. By default this is defined by the preprocessor constant <code>HPX_BUSY_LOOP_COUNT_MAX</code> . This is an internal setting that you should change only if you know exactly what you are doing.
hpx.max_idle_backoff_time	This setting defines the maximum time (in milliseconds) for the scheduler to sleep after <code>hpx.max_idle_loop_count</code> iterations. This setting is applicable only if <code>HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF</code> is set during configuration in CMake. By default this is defined by the preprocessor constant <code>HPX_IDLE_BACKOFF_TIME_MAX</code> . This is an internal setting that you should change only if you know exactly what you are doing.
hpx.exception_verbose	This setting defines the verbosity of exceptions. Valid values are integers. A setting of 2 or higher prints all available information. A setting of 1 leaves out the build configuration and environment variables. A setting of 0 or lower prints only the description of the thrown exception and the file name, function, and line number where the exception was thrown. The default value is 2 or the value of the environment variable <code>HPX_EXCEPTION_VERTOSITY</code> .
hpx.stack_size	This is initialized to the small stack size to be used by <i>HPX</i> threads. Set by default to the value of the compile time preprocessor constant <code>HPX_SMALL_STACK_SIZE</code> (defaults to <code>0x8000</code> ). This value is used for all <i>HPX</i> threads by default, except for the thread running <code>hpx_main</code> (which runs on a large stack).
hpx.stack_size	This is initialized to the medium stack size to be used by <i>HPX</i> threads. Set by default to the value of the compile time preprocessor constant <code>HPX_MEDIUM_STACK_SIZE</code> (defaults to <code>0x20000</code> ). <span style="float: right;">83</span>
hpx.stack_size	This is initialized to the large stack size to be used by <i>HPX</i> threads. Set by default to the value of the compile time preprocessor constant <code>HPX_LARGE_STACK_SIZE</code> (defaults to <code>0x200000</code> ). This setting

## The hpx.threadpools configuration section

```
[hpx.threadpools]
io_pool_size = ${HPX_NUM_IO_POOL_SIZE:2}
parcel_pool_size = ${HPX_NUM_PARCEL_POOL_SIZE:2}
timer_pool_size = ${HPX_NUM_TIMER_POOL_SIZE:2}
```

Property	Description
hpx.threadpools. io_pool_size	The value of this property defines the number of OS threads created for the internal I/O thread pool.
hpx.threadpools. parcel_pool_size	The value of this property defines the number of OS threads created for the internal parcel thread pool.
hpx.threadpools. timer_pool_size	The value of this property defines the number of OS threads created for the internal timer thread pool.

## The hpx.thread\_queue configuration section

**Important:** These are the setting control internal values used by the thread scheduling queues in the *HPX* scheduler. You should not modify these settings unless you know exactly what you are doing.

---

```
[hpx.thread_queue]
min_tasks_to_steal_pending = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_PENDING:0}
min_tasks_to_steal_staged = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_STAGE:0}
min_add_new_count = ${HPX_THREAD_QUEUE_MIN_ADD_NEW_COUNT:10}
max_add_new_count = ${HPX_THREAD_QUEUE_MAX_ADD_NEW_COUNT:10}
max_delete_count = ${HPX_THREAD_QUEUE_MAX_DELETE_COUNT:1000}
```

Property	Description
hpx.thread_queue. min_tasks_to_steal_pending	The value of this property defines the number of pending <i>HPX</i> threads that have to be available before neighboring cores are allowed to steal work. The default is to allow stealing always.
hpx.thread_queue. min_tasks_to_steal_staged	The value of this property defines the number of staged <i>HPX</i> tasks that need to be available before neighboring cores are allowed to steal work. The default is to allow stealing always.
hpx.thread_queue. min_add_new_count	The value of this property defines the minimal number of tasks to be converted into <i>HPX</i> threads whenever the thread queues for a core have run empty.
hpx.thread_queue. max_add_new_count	The value of this property defines the maximal number of tasks to be converted into <i>HPX</i> threads whenever the thread queues for a core have run empty.
hpx.thread_queue. max_delete_count	The value of this property defines the number of terminated <i>HPX</i> threads to discard during each invocation of the corresponding function.

## The hpx.components configuration section

### [hpx.components]

```
load_external = ${HPX_LOAD_EXTERNAL_COMPONENTS:1}
```

Property	Description
hpx.components.load_external	This entry defines whether external components will be loaded on this <i>locality</i> . This entry is normally set to 1, and usually there is no need to directly change this value. It is automatically set to 0 for a dedicated AGAS server <i>locality</i> .

Additionally, the section hpx.components will be populated with the information gathered from all found components. The information loaded for each of the components will contain at least the following properties:

### [hpx.components.<component\_instance\_name>]

```
name = <component_name>
path = <full_path_of_the_component_module>
enabled = ${[hpx.components.load_external]}
```

Property	Description
hpx.components.<component_instance_name>.name	This is the name of a component, usually the same as the second argument to the macro used while registering the component with <i>HPX_REGISTER_COMPONENT</i> . Set by the component factory.
hpx.components.<component_instance_name>.path	This is either the full path file name of the component module or the directory the component module is located in. In this case, the component module name will be derived from the property hpx.components.<component_instance_name>.name. Set by the component factory.
hpx.components.<component_instance_name>.enabled	This setting explicitly enables or disables the component. This is an optional property. HPX assumes that the component is enabled if it is not defined.

The value for <component\_instance\_name> is usually the same as for the corresponding name property. However, generally it can be defined to any arbitrary instance name. It is used to distinguish between different ini sections, one for each component.

## The hpx.parcel configuration section

### [hpx.parcel]

```
address = ${HPX_PARCEL_SERVER_ADDRESS:<hpx_initial_ip_address>}
port = ${HPX_PARCEL_SERVER_PORT:<hpx_initial_ip_port>}
bootstrap = ${HPX_PARCEL_BOOTSTRAP:<hpx_parcel_bootstrap>}
max_connections = ${HPX_PARCEL_MAX_CONNECTIONS:<hpx_parcel_max_connections>}
max_connections_per_locality = ${HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY:<hpx_parcel_max_
→connections_per_locality>}
max_message_size = ${HPX_PARCEL_MAX_MESSAGE_SIZE:<hpx_parcel_max_message_size>}
max_outbound_message_size = ${HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE:<hpx_parcel_max_
→outbound_message_size>}
array_optimization = ${HPX_PARCEL_ARRAY_OPTIMIZATION:1}
zero_copy_optimization = ${HPX_PARCEL_ZERO_COPY_OPTIMIZATION:$[hpx.parcel.array_
→optimization]}
```

(continues on next page)

(continued from previous page)

```
async_serialization = ${HPX_PARCEL_ASYNC_SERIALIZATION:1}
message_handlers = ${HPX_PARCEL_MESSAGE_HANDLERS:0}
```

Property	Description
hpx.parcel.address	This property defines the default IP address to be used for the <i>parcel</i> layer to listen to. This IP address will be used as long as no other values are specified (for instance, using the <code>--hpx:hpx</code> command line option). The expected format is any valid IP address or domain name format that can be resolved into an IP address. The default depends on the compile time preprocessor constant <code>HPX_INITIAL_IP_ADDRESS</code> ("127.0.0.1").
hpx.parcel.port	This property defines the default IP port to be used for the <i>parcel</i> layer to listen to. This IP port will be used as long as no other values are specified (for instance using the <code>--hpx:hpx</code> command line option). The default depends on the compile time preprocessor constant <code>HPX_INITIAL_IP_PORT</code> (7910).
hpx.parcel.bootstrap	This property defines which parcelport type should be used during application bootstrap. The default depends on the compile time preprocessor constant <code>HPX_PARCEL_BOOTSTRAP</code> ("tcp").
hpx.parcel.max_connections	This property defines how many network connections between different localities are overall kept alive by each <i>locality</i> . The default depends on the compile time preprocessor constant <code>HPX_PARCEL_MAX_CONNECTIONS</code> (512).
hpx.parcel.max_connections_per_locality	This property defines the maximum number of network connections that one <i>locality</i> will open to another <i>locality</i> . The default depends on the compile time preprocessor constant <code>HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY</code> (4).
hpx.parcel.max_message_size	This property defines the maximum allowed message size that will be transferrable through the <i>parcel</i> layer. The default depends on the compile time preprocessor constant <code>HPX_PARCEL_MAX_MESSAGE_SIZE</code> (1000000000 bytes).
hpx.parcel.max_outbound_message_size	This property defines the maximum allowed outbound coalesced message size that will be transferrable through the parcel layer. The default depends on the compile time preprocessor constant <code>HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE</code> (1000000 bytes).
hpx.parcel.array_optimization	This property defines whether this <i>locality</i> is allowed to utilize array optimizations during serialization of <i>parcel</i> data. The default is 1.
hpx.parcel.zero_copy_optimization	This property defines whether this <i>locality</i> is allowed to utilize zero copy optimizations during serialization of <i>parcel</i> data. The default is the same value as set for <code>hpx.parcel.array_optimization</code> .
hpx.parcel.zero_copy_serialization_threshold	This property defines the threshold value (in bytes) starting at which the serialization layer will apply zero-copy optimizations for serialized entities. The default value is defined by the preprocessor constant <code>HPX_ZERO_COPY_THRESHOLD</code> .
hpx.parcel.async_serialization	This property defines whether this <i>locality</i> is allowed to spawn a new thread for serialization (this is both for encoding and decoding parcels). The default is 1.
hpx.parcel.message_handlers	This property defines whether message handlers are loaded. The default is 0.
hpx.parcel.max_background_threads	This property defines how many cores should be used to perform background operations. The default is -1 (all cores).

The following settings relate to the TCP/IP parcelport.

```
[hpx.parcel.tcp]
enable = ${HPX_HAVE_PARCELPORT_TCP:$[hpx.parcel.enabled]}
```

(continues on next page)

(continued from previous page)

```

array_optimization = ${HPX_PARCEL_TCP_ARRAY_OPTIMIZATION}:[hpx.parcel.array_
    ↵optimization]
zero_copy_optimization = ${HPX_PARCEL_TCP_ZERO_COPY_OPTIMIZATION}:[hpx.parcel.zero_copy_
    ↵optimization]
zero_copy_serialization_threshold = ${HPX_PARCEL_TCP_ZERO_COPY_SERIALIZATION_THRESHOLD}:
    ↵${[hpx.parcel.zero_copy_serialization_threshold]}
async_serialization = ${HPX_PARCEL_TCP_ASYNC_SERIALIZATION}:[hpx.parcel.async_
    ↵serialization]
parcel_pool_size = ${HPX_PARCEL_TCP_PARCEL_POOL_SIZE}:[hpx.threadpools.parcel_pool_size]
max_connections = ${HPX_PARCEL_TCP_MAX_CONNECTIONS}:[hpx.parcel.max_connections]
max_connections_per_locality = ${HPX_PARCEL_TCP_MAX_CONNECTIONS_PER_LOCALITY}:[hpx.
    ↵parcel.max_connections_per_locality]
max_message_size = ${HPX_PARCEL_TCP_MAX_MESSAGE_SIZE}:[hpx.parcel.max_message_size]
max_outbound_message_size = ${HPX_PARCEL_TCP_MAX_OUTBOUND_MESSAGE_SIZE}:[hpx.parcel.max_
    ↵outbound_message_size]
max_background_threads = ${HPX_PARCEL_TCP_MAX_BACKGROUND_THREADS}:[hpx.parcel.max_
    ↵background_threads]

```

Property	Description
hpx.parcel.tcp.enable	Enables the use of the default TCP parcelport. Note that the initial bootstrap of the overall HPX application will be performed using the default TCP connections. This parcelport is enabled by default. This will be disabled only if MPI is enabled (see below).
hpx.parcel.tcp.array_optimization	This property defines whether this <i>locality</i> is allowed to utilize array optimizations in the TCP/IP parcelport during serialization of parcel data. The default is the same value as set for hpx.parcel.array_optimization.
hpx.parcel.tcp.zero_copy_optimization	This property defines whether this <i>locality</i> is allowed to utilize zero copy optimizations in the TCP/IP parcelport during serialization of parcel data. The default is the same value as set for hpx.parcel.zero_copy_optimization.
hpx.parcel.tcp.zero_copy_serialization_threshold	This property defines the threshold value (in bytes) starting at which the serialization layer applies optimizations for serialized entities. The default is the same value as set for hpx.parcel.zero_copy_serialization_threshold.
hpx.parcel.tcp.async_serialization	This property defines whether this <i>locality</i> is allowed to spawn a new thread for serialization in the TCP/IP parcelport (this is both for encoding and decoding parcels). The default is the same value as set for hpx.parcel.async_serialization.
hpx.parcel.tcp.parcel_pool_size	The value of this property defines the number of OS threads created for the internal parcel thread pool of the TCP <i>parcel</i> port. The default is taken from hpx.threadpools.parcel_pool_size.
hpx.parcel.tcp.max_connections	This property defines how many network connections between different localities are overall kept alive by each <i>locality</i> . The default is taken from hpx.parcel.max_connections.
hpx.parcel.tcp.max_connections_per_locality	This property defines the maximum number of network connections that one <i>locality</i> is open to another <i>locality</i> . The default is taken from hpx.parcel.max_connections_per_locality.
hpx.parcel.tcp.max_message_size	This property defines the maximum allowed message size that will be transferrable through the <i>parcel</i> layer. The default is taken from hpx.parcel.max_message_size.
hpx.parcel.tcp.max_outbound_message_size	This property defines the maximum allowed outbound coalesced message size that will be transferrable through the <i>parcel</i> layer. The default is taken from hpx.parcel.max_outbound_connections.
hpx.parcel.tcp.max_background_threads	This property defines how many cores should be used to perform background operations. This default is taken from hpx.parcel.max_background_threads.

The following settings relate to the MPI parcelport. These settings take effect only if the compile time constant

HPX\_HAVE\_PARCELPORT\_MPI is set (the equivalent CMake variable is HPX\_WITH\_PARCELPORT\_MPI and has to be set to ON).

```
[hpx.parcel mpi]
enable = ${HPX_HAVE_PARCELPORT_MPI:$[hpx.parcel.enabled]}
env = ${HPX_HAVE_PARCELPORT_MPI_ENV:MV2_COMM_WORLD_RANK,PMI_RANK,OMPI_COMM_WORLD_SIZE,
      ↳ALPS_APP_PE,PALS_NODEID}
multithreaded = ${HPX_HAVE_PARCELPORT_MPI_MULTITHREADED:1}
rank = <MPI_rank>
processor_name = <MPI_processor_name>
array_optimization = ${HPX_HAVE_PARCEL_MPI_ARRAY_OPTIMIZATION:$[hpx.parcel.array_
      ↳optimization]}
zero_copy_optimization = ${HPX_HAVE_PARCEL_MPI_ZERO_COPY_OPTIMIZATION:$[hpx.parcel.zero_
      ↳copy_optimization]}
zero_copy_serialization_threshold = ${HPX_PARCEL_MPI_ZERO_COPY_SERIALIZATION_THRESHOLD:
      ↳$[hpx.parcel.zero_copy_serialization_threshold]}
use_io_pool = ${HPX_HAVE_PARCEL_MPI_USE_IO_POOL:$1}
async_serialization = ${HPX_HAVE_PARCEL_MPI_ASYNC_SERIALIZATION:$[hpx.parcel.async_
      ↳serialization]}
parcel_pool_size = ${HPX_HAVE_PARCEL_MPI_PARCEL_POOL_SIZE:$[hpx.threadpools.parcel_pool_
      ↳size]}
max_connections = ${HPX_HAVE_PARCEL_MPI_MAX_CONNECTIONS:$[hpx.parcel.max_connections]}
max_connections_per_locality = ${HPX_HAVE_PARCEL_MPI_MAX_CONNECTIONS_PER_LOCALITY:$[hpx.
      ↳parcel.max_connections_per_locality]}
max_message_size = ${HPX_HAVE_PARCEL_MPI_MAX_MESSAGE_SIZE:$[hpx.parcel.max_message_
      ↳size]}
max_outbound_message_size = ${HPX_HAVE_PARCEL_MPI_MAX_OUTBOUND_MESSAGE_SIZE:$[hpx.
      ↳parcel.max_outbound_message_size]}
max_background_threads = ${HPX_PARCEL_MPI_MAX_BACKGROUND_THREADS:$[hpx.parcel.max_
      ↳background_threads]}
```

Property	Description
<code>hpx.parcel.mpi.enable</code>	Enables the use of the MPI parcelport. <i>HPX</i> tries to detect if the application was started within a parallel MPI environment. If the detection was successful, the MPI parcelport is enabled by default. To explicitly disable the MPI parcelport, set to 0. Note that the initial bootstrap of the overall <i>HPX</i> application will be performed using MPI as well.
<code>hpx.parcel.mpi.env</code>	This property influences which environment variables (separated by commas) will be analyzed to find out whether the application was invoked by MPI.
<code>hpx.parcel.mpi.multithreaded</code>	This property is used to determine what threading mode to use when initializing MPI. If this setting is 0, <i>HPX</i> will initialize MPI with <code>MPI_THREAD_SINGLE</code> . If the value is not equal to 0, <i>HPX</i> will initialize MPI with <code>MPI_THREAD_MULTI</code> .
<code>hpx.parcel.mpi.rank</code>	This property will be initialized to the MPI rank of the <i>locality</i> .
<code>hpx.parcel.mpi.processor_name</code>	This property will be initialized to the MPI processor name of the <i>locality</i> .
<code>hpx.parcel.mpi.array_optimization</code>	This property defines whether this <i>locality</i> is allowed to utilize array optimizations in the MPI parcelport during serialization of <i>parcel</i> data. The default is the same value as set for <code>hpx.parcel.array_optimization</code> .
<code>hpx.parcel.mpi.zero_copy_optimization</code>	This property defines whether this <i>locality</i> is allowed to utilize zero copy optimizations in the MPI parcelport during serialization of parcel data. The default is the same value as set for <code>hpx.parcel.zero_copy_optimization</code> .
<code>hpx.parcel.mpi.zero_copy_serialization_threshold</code>	This property defines the threshold value (in bytes) starting at which the serialization layer will apply zero-copy optimizations for serialized entities. The default is the same value as set for <code>hpx.parcel.serialization_threshold</code> .
<code>hpx.parcel.mpi.use_io_pool</code>	This property can be set to run the progress thread inside of <i>HPX</i> threads instead of a separate thread pool. The default is 1.
<code>hpx.parcel.mpi.async_serialization_thread</code>	This property defines whether this <i>locality</i> is allowed to spawn a new thread for serialization in the MPI parcelport (this is both for encoding and decoding parcels). The default is the same value as set for <code>hpx.parcel.async_serialization</code> .
<code>hpx.parcel.mpi.parcel_pool_size</code>	The value of this property defines the number of OS threads created for the internal parcel thread pool of the MPI <i>parcel</i> port. The default is taken from <code>hpx.threadpools.parcel_pool_size</code> .
<code>hpx.parcel.mpi.max_connections</code>	This property defines how many network connections between different localities are overall kept alive by each <i>locality</i> . The default is taken from <code>hpx.parcel.max_connections</code> .
<code>hpx.parcel.mpi.max_connections_per_locality</code>	This property defines the maximum number of network connections that one <i>locality</i> will open to another <i>locality</i> . The default is taken from <code>hpx.parcel.max_connections_per_locality</code> .
<code>hpx.parcel.mpi.max_message_size</code>	This property defines the maximum allowed message size that will be transferrable through the <i>parcel</i> layer. The default is taken from <code>hpx.parcel.max_message_size</code> .
<code>hpx.parcel.mpi.max_outbound_message_size_and_connections</code>	This property defines the maximum allowed outbound coalesced message size that will be transferrable through the <i>parcel</i> layer. The default is taken from <code>hpx.parcel.message_size_and_connections</code> .
<code>hpx.parcel.tcp.max_background_threads</code>	This property defines how many cores should be used to perform background operations. The default is taken from <code>hpx.parcel.max_background_threads</code> .

## The hpx.agas configuration section

```
[hpx.agas]
address = ${HPX_AGAS_SERVER_ADDRESS:<hpx_initial_ip_address>}
port = ${HPX_AGAS_SERVER_PORT:<hpx_initial_ip_port>}
service_mode = hosted
dedicated_server = 0
max_pending_refcnt_requests = ${HPX_AGAS_MAX_PENDING_REFCNT_REQUESTS:<hpx_initial_agas_
    ↵max_pending_refcnt_requests>}
use_caching = ${HPX_AGAS_USE_CACHING:1}
use_range_caching = ${HPX_AGAS_USE_RANGE_CACHING:1}
local_cache_size = ${HPX_AGAS_LOCAL_CACHE_SIZE:<hpx_agas_local_cache_size>}
```

Property	Description
hpx. agas. address	This property defines the default IP address to be used for the <i>AGAS</i> root server. This IP address will be used as long as no other values are specified (for instance, using the <code>--hpx:agas</code> command line option). The expected format is any valid IP address or domain name format that can be resolved into an IP address. The default depends on the compile time preprocessor constant <code>HPX_INITIAL_IP_ADDRESS</code> ("127.0.0.1").
hpx. agas. port	This property defines the default IP port to be used for the <i>AGAS</i> root server. This IP port will be used as long as no other values are specified (for instance, using the <code>--hpx:agas</code> command line option). The default depends on the compile time preprocessor constant <code>HPX_INITIAL_IP_PORT</code> (7009).
hpx. agas. service_mode	This property specifies what type of <i>AGAS</i> service is running on this <i>locality</i> . Currently, two modes exist. The <i>locality</i> that acts as the <i>AGAS</i> server runs in <b>bootstrap</b> mode. All other localities are in <b>hosted</b> mode.
hpx. agas. dedicated	This property specifies whether the <i>AGAS</i> server is exclusively running <i>AGAS</i> services and not hosting any application components. It is a boolean value. Set to 1 if <code>--hpx:run-agas-server-only</code> is present.
hpx. agas. max_pending_refcnt_requests	This property defines the number of reference counting requests (increments or decrements) to buffer. The default depends on the compile time preprocessor constant <code>HPX_INITIAL_AGAS_MAX_PENDING_REFCNT_REQUESTS</code> (4096).
hpx. agas. use_caching	This property specifies whether a software address translation cache is used. It is a boolean value. Defaults to 1.
hpx. agas. use_range_caching	This property specifies whether range-based caching is used by the software address translation cache. This property is ignored if <code>hpx.agas.use_caching</code> is false. It is a boolean value. Defaults to 1.
hpx. agas. local_cache_size	This property defines the size of the software address translation cache for <i>AGAS</i> services. This property is ignored if <code>hpx.agas.use_caching</code> is false. Note that if <code>hpx.agas.use_range_caching</code> is true, this size will refer to the maximum number of ranges stored in the cache, not the number of entries spanned by the cache. The default depends on the compile time preprocessor constant <code>HPX_AGAS_LOCAL_CACHE_SIZE</code> (4096).

## The hpx.commandline configuration section

The following table lists the definition of all pre-defined command line option shortcuts. For more information about commandline options, see the section [HPX Command Line Options](#).

```
[hpx.commandline]
aliasing = ${HPX_COMMANDLINE_ALIASING:1}
allow_unknown = ${HPX_COMMANDLINE_ALLOW_UNKNOWN:0}

[hpx.commandline.aliases]
-a = --hpx:agas
-c = --hpx:console
-h = --hpx:help
-I = --hpx:ini
-l = --hpx:localities
-p = --hpx:app-config
-q = --hpx:queuing
-r = --hpx:run-agas-server
-t = --hpx:threads
-v = --hpx:version
-w = --hpx:worker
-x = --hpx:hpx
-0 = --hpx:node=0
-1 = --hpx:node=1
-2 = --hpx:node=2
-3 = --hpx:node=3
-4 = --hpx:node=4
-5 = --hpx:node=5
-6 = --hpx:node=6
-7 = --hpx:node=7
-8 = --hpx:node=8
-9 = --hpx:node=9
```

Property	Description
<code>hpx.commandline. aliasing</code>	Enable command line aliases as defined in the section <code>hpx.commandline. aliases</code> (see below). Defaults to 1.
<code>hpx.commandline. allow_unknown</code>	Allow for unknown command line options to be passed through to <code>hpx_main()</code> . Defaults to 0.
<code>hpx.commandline. aliases.-a</code>	On the commandline -a expands to: <code>--hpx:agas</code> .
<code>hpx.commandline. aliases.-c</code>	On the commandline -c expands to: <code>--hpx:console</code> .
<code>hpx.commandline. aliases.-h</code>	On the commandline -h expands to: <code>--hpx:help</code> .
<code>hpx.commandline. aliases.--help</code>	On the commandline --help expands to: <code>--hpx:help</code> .
<code>hpx.commandline. aliases.-I</code>	On the commandline -I expands to: <code>--hpx:ini</code> .
<code>hpx.commandline. aliases.-l</code>	On the commandline -l expands to: <code>--hpx:localities</code> .
<code>hpx.commandline. aliases.-p</code>	On the commandline -p expands to: <code>--hpx:app-config</code> .
<code>hpx.commandline. aliases.-q</code>	On the commandline -q expands to: <code>--hpx:queuing</code> .
<code>hpx.commandline. aliases.-r</code>	On the commandline -r expands to: <code>--hpx:run-agas-server</code> .
<code>hpx.commandline. aliases.-t</code>	On the commandline -t expands to: <code>--hpx:threads</code> .
<code>hpx.commandline. aliases.-v</code>	On the commandline -v expands to: <code>--hpx:version</code> .
<code>hpx.commandline. aliases.--version</code>	On the commandline --version expands to: <code>--hpx:version</code> .
<code>hpx.commandline. aliases.-w</code>	On the commandline -w expands to: <code>--hpx:worker</code> .
<code>hpx.commandline. aliases.-x</code>	On the commandline -x expands to: <code>--hpx:hpx</code> .
<code>hpx.commandline. aliases.-0</code>	On the commandline -0 expands to: <code>--hpx:node=0</code> .
<code>hpx.commandline. aliases.-1</code>	On the commandline -1 expands to: <code>--hpx:node=1</code> .
<code>hpx.commandline. aliases.-2</code>	On the commandline -2 expands to: <code>--hpx:node=2</code> .
<code>hpx.commandline. aliases.-3</code>	On the commandline -3 expands to: <code>--hpx:node=3</code> .
<code>hpx.commandline. aliases.-4</code>	On the commandline -4 expands to: <code>--hpx:node=4</code> .
<code>hpx.commandline. aliases.-5</code>	On the commandline -5 expands to: <code>--hpx:node=5</code> .
<code>hpx.commandline. aliases.-6</code>	On the commandline -6 expands to: <code>--hpx:node=6</code> .
<code>hpx.commandline. aliases.-7</code>	On the commandline -7 expands to: <code>--hpx:node=7</code> .
<code>hpx.commandline. aliases.-8</code>	On the commandline -8 expands to: <code>--hpx:node=8</code> .
<code>hpx.commandline. aliases.-9</code>	On the commandline -9 expands to: <code>--hpx:node=9</code> .

## Loading INI files

During startup and after the internal database has been initialized as described in the section [Built-in default configuration settings](#), *HPX* will try to locate and load additional ini files to be used as a source for configuration properties. This allows for a wide spectrum of additional customization possibilities by the user and system administrators. The sequence of locations where *HPX* will try loading the ini files is well defined and documented in this section. All ini files found are merged into the internal configuration database. The merge operation itself conforms to the rules as described in the section [The HPX ini file format](#).

1. Load all component shared libraries found in the directories specified by the property `hpx.component_path` and retrieve their default configuration information (see section [Loading components](#) for more details). This property can refer to a list of directories separated by ':' (Linux, Android, and MacOS) or by ';' (Windows).
2. Load all files named `hpx.ini` in the directories referenced by the property `hpx.master_ini_path`. This property can refer to a list of directories separated by ':' (Linux, Android, and MacOS) or by ';' (Windows).
3. Load a file named `.hpx.ini` in the current working directory, e.g., the directory the application was invoked from.
4. Load a file referenced by the environment variable `HPX_INI`. This variable is expected to provide the full path name of the ini configuration file (if any).
5. Load a file named `/etc/hpx.ini`. This lookup is done on non-Windows systems only.
6. Load a file named `.hpx.ini` in the home directory of the current user, e.g., the directory referenced by the environment variable `HOME`.
7. Load a file named `.hpx.ini` in the directory referenced by the environment variable `PWD`.
8. Load the file specified on the command line using the option `--hpx:config`.
9. Load all properties specified on the command line using the option `--hpx:ini`. The properties will be added to the database in the same sequence as they are specified on the command line. The format for those options is, for instance, `--hpx:ini=hpx.default_stack_size=0x4000`. In addition to the explicit command line options, this will set the following properties as implied from other settings:
  - `hpx.parcel.address` and `hpx.parcel.port` as set by `--hpx:hpx`
  - `hpx.agas.address`, `hpx.agas.port` and `hpx.agas.service_mode` as set by `--hpx:agas`
  - `hpx.program_name` and `hpx.cmd_line` will be derived from the actual command line
  - **`hpx.os_threads` and `hpx.localities` as set by `--hpx:threads` and `--hpx:localities`**
  - `hpx.runtime_mode` will be derived from any explicit `--hpx:console`, `--hpx:worker`, or `--hpx:connect`, or it will be derived from other settings, such as `--hpx:node =0`, which implies `--hpx:console`.
10. Load files based on the pattern `*.ini` in all directories listed by the property `hpx.ini_path`. All files found during this search will be merged. The property `hpx.ini_path` can hold a list of directories separated by ':' (on Linux or Mac) or ';' (on Windows).
11. Load the file specified on the command line using the option `--hpx:app-config`. Note that this file will be merged as the content for a top level section `[application]`.

---

**Note:** Any changes made to the configuration database caused by one of the steps will influence the loading process for all subsequent steps. For instance, if one of the ini files loaded changes the property `hpx.ini_path`, this will influence the directories searched in step 9 as described above.

---

---

**Important:** The *HPX* core library will verify that all configuration settings specified on the command line (using the `--hpx:ini` option) will be checked for validity. That means that the library will accept only *known* configuration settings. This is to protect the user from unintentional typos while specifying those settings. This behavior can be overwritten by appending a '!' to the configuration key, thus forcing the setting to be entered into the configuration database. For instance: `--hpx:ini=hpx.foo! = 1`

---

If any of the environment variables or files listed above are not found, the corresponding loading step will be silently skipped.

## Loading components

*HPX* relies on loading application specific components during the runtime of an application. Moreover, *HPX* comes with a set of preinstalled components supporting basic functionalities useful for almost every application. Any component in *HPX* is loaded from a shared library, where any of the shared libraries can contain more than one component type. During startup, *HPX* tries to locate all available components (e.g., their corresponding shared libraries) and creates an internal component registry for later use. This section describes the algorithm used by *HPX* to locate all relevant shared libraries on a system. As described, this algorithm is customizable by the configuration properties loaded from the ini files (see section [Loading INI files](#)).

Loading components is a two-stage process. First *HPX* tries to locate all component shared libraries, loads those, and generates a default configuration section in the internal configuration database for each component found. For each found component the following information is generated:

```
[hpx.components.<component_instance_name>]
name = <name_of_shared_library>
path = $[component_path]
enabled = $[hpx.components.load_external]
default = 1
```

The values in this section correspond to the expected configuration information for a component as described in the section [Built-in default configuration settings](#).

In order to locate component shared libraries, *HPX* will try loading all shared libraries (files with the platform specific extension of a shared library, Linux: \*.so, Windows: \*.dll, MacOS: \*.dylib found in the directory referenced by the ini property `hpx.component_path`).

This first step corresponds to step 1) during the process of filling the internal configuration database with default information as described in section [Loading INI files](#).

After all of the configuration information has been loaded, *HPX* performs the second step in terms of loading components. During this step, *HPX* scans all existing configuration sections `[hpx.component.<some_component_instance_name>]` and instantiates a special factory object for each of the successfully located and loaded components. During the application's life time, these factory objects are responsible for creating new and discarding old instances of the component they are associated with. This step is performed after step 11) of the process of filling the internal configuration database with default information as described in section [Loading INI files](#).

## Application specific component example

This section assumes there is a simple application component that exposes one member function as a component action. The header file `app_server.hpp` declares the C++ type to be exposed as a component. This type has a member function `print_greeting()`, which is exposed as an action `print_greeting_action`. We assume the source files for this example are located in a directory referenced by `$APP_ROOT`:

```
// file: $APP_ROOT/app_server.hpp
#include <hpx/hpx.hpp>
#include <hpx/include/iostreams.hpp>

namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
        : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
    };
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);
```

The corresponding source file contains mainly macro invocations that define the boilerplate code needed for *HPX* to function properly:

```
// file: $APP_ROOT/app_server.cpp
#include "app_server.hpp"

// Define boilerplate required once per component module.
HPX_REGISTER_COMPONENT_MODULE();

// Define factory object associated with our component of type 'app::server'.
HPX_REGISTER_COMPONENT(app::server, app_server);

// Define boilerplate code required for each of the component actions. Use the
// same argument as used for HPX_REGISTER_ACTION_DECLARATION above.
HPX_REGISTER_ACTION(app::server::print_greeting_action);
```

The following gives an example of how the component can be used. Here, one instance of the `app::server` component is created on the current *locality* and the exposed action `print_greeting_action` is invoked using the global id of the newly created instance. Note that no special code is required to delete the component instance after it is not needed anymore. It will be deleted automatically when its last reference goes out of scope (shown in the example below at the closing brace of the block surrounding the code):

```
// file: $APP_ROOT/use_app_server_example.cpp
#include <hpx/hpx_init.hpp>
#include "app_server.hpp"

int hpx_main()
{
    {
        // Create an instance of the app_server component on the current locality.
        hpx::naming::id_type app_server_instance =
            hpx::create_component<app::server>(hpx::find_here());

        // Create an instance of the action 'print_greeting_action'.
        app::server::print_greeting_action print_greeting;

        // Invoke the action 'print_greeting' on the newly created component.
        print_greeting(app_server_instance);
    }
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```

In order to make sure that the application will be able to use the component `app::server`, special configuration information must be passed to *HPX*. The simplest way to allow *HPX* to ‘find’ the component is to provide special ini configuration files that add the necessary information to the internal configuration database. The component should have a special ini file containing the information specific to the component `app_server`.

```
# file: $APP_ROOT/app_server.ini
[hpx.components.app_server]
name = app_server
path = $APP_LOCATION/
```

Here, `$APP_LOCATION` is the directory where the (binary) component shared library is located. *HPX* will attempt to load the shared library from there. The section name `hpx.components.app_server` reflects the instance name of the component (`app_server` is an arbitrary, but unique name). The property value for `hpx.components.app_server.name` should be the same as used for the second argument to the macro `HPX_REGISTER_COMPONENT` above.

Additionally, a file `.hpx.ini`, which could be located in the current working directory (see step 3 as described in the section [Loading INI files](#)), can be used to add to the ini search path for components:

```
# file: $PWD/.hpx.ini
[hpx]
ini_path = ${hpx.ini_path}:$APP_ROOT/
```

This assumes that the above ini file specific to the component is located in the directory `$APP_ROOT`.

---

**Note:** It is possible to reference the defined property from inside its value. *HPX* will gracefully use the previous value of `hpx.ini_path` for the reference on the right hand side and assign the overall (now expanded) value to the property.

## Logging

HPX uses a sophisticated logging framework, allowing users to follow in detail what operations have been performed inside the HPX library in what sequence. This information proves to be very useful for diagnosing problems or just for improving the understanding of what is happening in HPX as a consequence of invoking HPX API functionality.

### Default logging

Enabling default logging is a simple process. The detailed description in the remainder of this section explains different ways to customize the defaults. Default logging can be enabled by using one of the following:

- A command line switch `--hpx:debug-hpx-log`, which will enable logging to the console terminal.
- The command line switch `--hpx:debug-hpx-log=<filename>`, which enables logging to a given file `<filename>`.
- Setting an environment variable `HPX_LOGLEVEL=<loglevel>` while running the HPX application. In this case `<loglevel>` should be a number between (or equal to) 1 and 5 where 1 means minimal logging and 5 causes all available messages to be logged. When setting the environment variable, the logs will be written to a file named `hpx.<PID>.lo` in the current working directory, where `<PID>` is the process id of the console instance of the application.

### Customizing logging

Generally, logging can be customized either using environment variable settings or using by an ini configuration file. Logging is generated in several categories, each of which can be customized independently. All customizable configuration parameters have reasonable defaults, allowing for the use of logging without any additional configuration effort. The following table lists the available categories.

Table 2.5: Logging categories

Category	Category shortcut	Information to be generated	Environment variable
General	None	Logging information generated by different subsystems of HPX, such as thread-manager, parcel layer, LCOs, etc.	<code>HPX_LOGLEVEL</code>
<code>AGAS</code>	<code>AGAS</code>	Logging output generated by the <code>AGAS</code> subsystem	<code>HPX_AGAS_LOGLEVEL</code>
Application	APP	Logging generated by applications.	<code>HPX_APP_LOGLEVEL</code>

By default, all logging output is redirected to the console instance of an application, where it is collected and written to a file, one file for each logging category.

Each logging category can be customized at two levels. The parameters for each are stored in the ini configuration sections `hpx.logging.CATEGORY` and `hpx.logging.console.CATEGORY` (where `CATEGORY` is the category shortcut as listed in the table above). The former influences logging at the source `locality` and the latter modifies the logging behaviour for each of the categories at the console instance of an application.

## Levels

All *HPX* logging output has seven different logging levels. These levels can be set explicitly or through environment variables in the main *HPX* ini file as shown below. The logging levels and their associated integral values are shown in the table below, ordered from most verbose to least verbose. By default, all *HPX* logs are set to 0, e.g., all logging output is disabled by default.

Table 2.6: Logging levels

Logging level	Integral value
<debug>	5
<info>	4
<warning>	3
<error>	2
<fatal>	1
No logging	0

---

**Tip:** The easiest way to enable logging output is to set the environment variable corresponding to the logging category to an integral value as described in the table above. For instance, setting `HPX_LOGLEVEL=5` will enable full logging output for the general category. Please note that the syntax and means of setting environment variables varies between operating systems.

---

## Configuration

Logs will be saved to destinations as configured by the user. By default, logging output is saved on the console instance of an application to `hpx.<CATEGORY>.<PID>.lo` (where `CATEGORY` and `PID`) are placeholders for the category shortcut and the OS process id). The output for the general logging category is saved to `hpx.<PID>.log`. The default settings for the general logging category are shown here (the syntax is described in the section [The HPX ini file format](#)):

```
[hpx.logging]
level = ${HPX_LOGLEVEL:0}
destination = ${HPX_LOGDESTINATION:console}
format = ${HPX_LOGFORMAT:(T%locality%/%hpxthread%.%hpxphase%/%hpxcomponent%) P%parentloc
˓%/%hpxparent%.%hpxparentphase% %time%($hh:$mm:$ss.$mili) [%idx%] |\\n}
```

The logging level is taken from the environment variable `HPX_LOGLEVEL` and defaults to zero, e.g., no logging. The default logging destination is read from the environment variable `HPX_LOGDESTINATION`. On any of the localities it defaults to `console`, which redirects all generated logging output to the console instance of an application. The following table lists the possible destinations for any logging output. It is possible to specify more than one destination separated by whitespace.

Table 2.7: Logging destinations

Logging destination	Description
file(<filename>)	Directs all output to a file with the given <filename>.
cout	Directs all output to the local standard output of the application instance on this <i>locality</i> .
cerr	Directs all output to the local standard error output of the application instance on this <i>locality</i> .
console	Directs all output to the console instance of the application. The console instance has its logging destinations configured separately.
android_log	Directs all output to the (Android) system log (available on Android systems only).

The logging format is read from the environment variable `HPX_LOGFORMAT`, and it defaults to a complex format description. This format consists of several placeholder fields (for instance `%locality%`), which will be replaced by concrete values when the logging output is generated. All other information is transferred verbatim to the output. The table below describes the available field placeholders. The separator character `|` separates the logging message prefix formatted as shown and the actual log message which will replace the separator.

Table 2.8: Available field placeholders

Name	Description
<code>locality</code>	The id of the <code>locality</code> on which the logging message was generated.
<code>hpxthread</code>	The id of the <code>HPX</code> thread generating this logging output.
<code>hpxphase</code>	The phase <sup>43</sup> of the <code>HPX</code> thread generating this logging output.
<code>hpxcomponent</code>	The local virtual address of the component which the current <code>HPX</code> thread is accessing.
<code>parentloc</code>	The id of the <code>locality</code> where the <code>HPX</code> thread was running that initiated the current <code>HPX</code> thread. The current <code>HPX</code> thread is generating this logging output.
<code>hpxparent</code>	The id of the <code>HPX</code> thread that initiated the current <code>HPX</code> thread. The current <code>HPX</code> thread is generating this logging output.
<code>hpxparentphase</code>	The phase of the <code>HPX</code> thread when it initiated the current <code>HPX</code> thread. The current <code>HPX</code> thread is generating this logging output.
<code>time</code>	The time stamp for this logging output line as generated by the source <code>locality</code> .
<code>idx</code>	The sequence number of the logging output line as generated on the source <code>locality</code> .
<code>osthread</code>	The sequence number of the OS thread that executes the current <code>HPX</code> thread.

---

**Note:** Not all of the field placeholder may be expanded for all generated logging output. If no value is available for a particular field, it is replaced with a sequence of '`-`' characters.

---

Here is an example line from a logging output generated by one of the `HPX` examples (please note that this is generated on a single line, without a line break):

```
(T00000000/0000000002d46f90.01/0000000009ebc10) P-----/0000000002d46f80.02 17:49.37.
↳ 320 [000000000000004d]
    <info> [RT] successfully created component {0000000100ff0001, 0000000000030002} of
↳ type: component_barrier[7(3)]
```

The default settings for the general logging category on the console is shown here:

```
[hpx.logging.console]
level = ${HPX_LOGLEVEL:$[hpx.logging.level]}
destination = ${HPX_CONSOLE_LOGDESTINATION:file(hpx.$[system.pid].log)}
format = ${HPX_CONSOLE_LOGFORMAT:|}
```

These settings define how the logging is customized once the logging output is received by the console instance of an application. The logging level is read from the environment variable `HPX_LOGLEVEL` (as set for the console instance of the application). The level defaults to the same values as the corresponding settings in the general logging configuration shown before. The destination on the console instance is set to be a file that's name is generated based on its OS process id. Setting the environment variable `HPX_CONSOLE_LOGDESTINATION` allows customization of the naming scheme for the output file. The logging format is set to leave the original logging output unchanged, as received from one of the localities the application runs on.

<sup>43</sup> The phase of a `HPX`-thread counts how often this thread has been activated.

## HPX Command Line Options

The predefined command line options for any application using `hpx::init` are described in the following subsections.

### HPX options (allowed on command line only)

#### --hpx:help

Print out program usage (default: this message). Possible values: `full` (additionally prints options from components).

#### --hpx:version

Print out HPX version and copyright information.

#### --hpx:info

Print out HPX configuration information.

#### --hpx:options-file arg

Specify a file containing command line options (alternatively: `@filepath`).

### HPX options (additionally allowed in an options file)

#### --hpx:worker

Run this instance in worker mode.

#### --hpx:console

Run this instance in console mode.

#### --hpx:connect

Run this instance in worker mode, but connecting late.

#### --hpx:run-agas-server

Run AGAS server as part of this runtime instance.

#### --hpx:run-hpx-main

Run the `hpx_main` function, regardless of `locality` mode.

#### --hpx:hpx arg

The IP address the HPX parcelport is listening on, expected format: `address:port` (default: `127.0.0.1:7910`).

#### --hpx:agas arg

The IP address the AGAS root server is running on, expected format: `address:port` (default: `127.0.0.1:7910`).

#### --hpx:run-agas-server-only

Run only the AGAS server.

#### --hpx:nodedefile arg

The file name of a node file to use (list of nodes, one node name per line and core).

#### --hpx:nodes arg

The (space separated) list of the nodes to use (usually this is extracted from a node file).

#### --hpx:endnodes

This can be used to end the list of nodes specified using the option `--hpx:nodes`.

**--hpx:ifsuffix arg**

Suffix to append to host names in order to resolve them to the proper network interconnect.

**--hpx:ifprefix arg**

Prefix to prepend to host names in order to resolve them to the proper network interconnect.

**--hpx:iftransform arg**

Sed-style search and replace (s/search/replace/) used to transform host names to the proper network interconnect.

**--hpx:localities arg**

The number of localities to wait for at application startup (default: 1).

**--hpx:node arg**

Number of the node this *locality* is run on (must be unique).

**--hpx:ignore-batch-env**

Ignore batch environment variables.

**--hpx:expect-connecting-localities**

This *locality* expects other localities to dynamically connect (this is implied if the number of initial localities is larger than 1).

**--hpx:pu-offset**

The first processing unit this instance of *HPX* should be run on (default: 0).

**--hpx:pu-step**

The step between used processing unit numbers for this instance of *HPX* (default: 1).

**--hpx:threads arg**

The number of operating system threads to spawn for this *HPX locality*. Possible values are: numeric values 1, 2, 3 and so on, all (which spawns one thread per processing unit, includes hyperthreads), or cores (which spawns one thread per core) (default: cores).

**--hpx:cores arg**

The number of cores to utilize for this *HPX locality* (default: all, i.e., the number of cores is based on the number of threads *--hpx:threads* assuming *--hpx:bind=compact*).

**--hpx:affinity arg**

The affinity domain the OS threads will be confined to, possible values: pu, core, numa, machine (default: pu).

**--hpx:bind arg**

he detailed affinity description for the OS threads, see *More details about HPX command line options* for a detailed description of possible values. Do not use with *--hpx:pu-step*, *--hpx:pu-offset* or *--hpx:affinity* options. Implies *--hpx:numa-sensitive* (*--hpx:bind=none*) disables defining thread affinities).

**--hpx:use-process-mask**

Use the process mask to restrict available hardware resources (implies *--hpx:ignore-batch-env*).

**--hpx:print-bind**

Print to the console the bit masks calculated from the arguments specified to all *--hpx:bind* options.

**--hpx:queuing arg**

The queue scheduling policy to use. Options are local, local-priority-fifo, local-priority-lifo, static, static-priority, abp-priority-fifo and abp-priority-lifo (default: local-priority-fifo).

**--hpx:high-priority-threads** arg

The number of operating system threads maintaining a high priority queue (default: number of OS threads), valid for `--hpx:queueing=abp-priority`, `--hpx:queueing=static-priority` and `--hpx:queueing=local-priority` only.

**--hpx:numa-sensitive**

Makes the scheduler NUMA sensitive.

**HPX configuration options****--hpx:app-config** arg

Load the specified application configuration (ini) file.

**--hpx:config** arg

Load the specified *HPX* configuration (ini) file.

**--hpx:ini** arg

Add a configuration definition to the default runtime configuration.

**--hpx:exit**

Exit after configuring the runtime.

**HPX debugging options****--hpx:list-symbolic-names**

List all registered symbolic names after startup.

**--hpx:list-component-types**

List all dynamic component types after startup.

**--hpx:dump-config-initial**

Print the initial runtime configuration.

**--hpx:dump-config**

Print the final runtime configuration.

**--hpx:debug-hpx-log** [arg]

Enable all messages on the *HPX* log channel and send all *HPX* logs to the target destination (default: `cout`).

**--hpx:debug-agas-log** [arg]

Enable all messages on the *AGAS* log channel and send all *AGAS* logs to the target destination (default: `cout`).

**--hpx:debug-parcel-log** [arg]

Enable all messages on the parcel transport log channel and send all parcel transport logs to the target destination (default: `cout`).

**--hpx:debug-timing-log** [arg]

Enable all messages on the timing log channel and send all timing logs to the target destination (default: `cout`).

**--hpx:debug-app-log** [arg]

Enable all messages on the application log channel and send all application logs to the target destination (default: `cout`).

**--hpx:debug-clp**

Debug command line processing.

**--hpx:attach-debugger arg**

Wait for a debugger to be attached, possible arg values: `startup` or `exception` (default: `startup`)

## HPX options related to performance counters

**--hpx:print-counter**

Print the specified performance counter either repeatedly and/or at the times specified by `--hpx:print-counter-at` (see also option `--hpx:print-counter-interval`).

**--hpx:print-counter-reset**

Print the specified performance counter either repeatedly and/or at the times specified by `--hpx:print-counter-at`. Reset the counter after the value is queried (see also option `--hpx:print-counter-interval`).

**--hpx:print-counter-interval**

Print the performance counter(s) specified with `--hpx:print-counter` repeatedly after the time interval (specified in milliseconds), (default: 0, which means print once at shutdown).

**--hpx:print-counter-destination**

Print the performance counter(s) specified with `--hpx:print-counter` to the given file (default: `console`).

**--hpx:list-counters**

List the names of all registered performance counters, possible values: `minimal` (prints counter name skeletons), `full` (prints all available counter names).

**--hpx:list-counter-infos**

List the description of all registered performance counters, possible values: `minimal` (prints info for counter name skeletons), `full` (prints all available counter infos).

**--hpx:print-counter-format**

Print the performance counter(s) specified with `--hpx:print-counter`. Possible formats in CSV include a format with a header or without any header (see option `--hpx:no-csv-header`). Possible values: `csv` (prints counter values in CSV format with full names as header), `csv-short` (prints counter values in CSV format with short names provided with `--hpx:print-counter` as `--hpx:print-counter` `shortname`, `full-countername`

**--hpx:no-csv-header**

Print the performance counter(s) specified with `--hpx:print-counter` and `csv` or `csv-short` format specified with `--hpx:print-counter-format` without header.

**--hpx:print-counter-at arg**

Print the performance counter(s) specified with `--hpx:print-counter` (or `--hpx:print-counter-reset`) at the given point in time, possible argument values: `startup`, `shutdown` (default), `noshutdown`.

**--hpx:reset-counters**

Reset all performance counter(s) specified with `--hpx:print-counter` after they have been evaluated.

**--hpx:print-counters-locally**

Each `locality` prints only its own local counters. If this is used with `--hpx:print-counter-destination=<file>`, the code will append a "`.<locality_id>`" to the file name in order to avoid clashes between localities.

## Command line argument shortcuts

Additionally, the following shortcuts are available from every *HPX* application.

Table 2.9: Predefined command line option shortcuts

Shortcut option	Equivalent long option
-a	--hpx:agas
-c	--hpx:console
-h	--hpx:help
-I	--hpx:ini
-l	--hpx:localities
-p	--hpx:app-config
-q	--hpx:queuing
-r	--hpx:run-agas-server
-t	--hpx:threads
-v	--hpx:version
-w	--hpx:worker
-x	--hpx:hpx
-0	--hpx:node=0
-1	--hpx:node=1
-2	--hpx:node=2
-3	--hpx:node=3
-4	--hpx:node=4
-5	--hpx:node=5
-6	--hpx:node=6
-7	--hpx:node=7
-8	--hpx:node=8
-9	--hpx:node=9

It is possible to define your own shortcut options. In fact, all of the shortcuts listed above are pre-defined using the technique described here. Also, it is possible to redefine any of the pre-defined shortcuts to expand differently as well.

Shortcut options are obtained from the internal configuration database. They are stored as key-value properties in a special properties section named `hpx.commandline`. You can define your own shortcuts by adding the corresponding definitions to one of the ini configuration files as described in the section [Configuring HPX applications](#). For instance, in order to define a command line shortcut `--p`, which should expand to `-hpx:print-counter`, the following configuration information needs to be added to one of the ini configuration files:

```
[hpx.commandline.aliases]
--pc = --hpx:print-counter
```

---

**Note:** Any arguments for shortcut options passed on the command line are retained and passed as arguments to the corresponding expanded option. For instance, given the definition above, the command line option:

```
--pc=/threads{locality#0/total}/count/cumulative
```

would be expanded to:

```
--hpx:print-counter=/threads{locality#0/total}/count/cumulative
```

---

**Important:** Any shortcut option should either start with a single '-' or with two '--' characters. Shortcuts starting

with a single '-' are interpreted as short options (i.e., everything after the first character following the '-' is treated as the argument). Shortcuts starting with '--' are interpreted as long options. No other shortcut formats are supported.

---

## Specifying options for single localities only

For runs involving more than one *locality*, it is sometimes desirable to supply specific command line options to single localities only. When the *HPX* application is launched using a scheduler (like PBS; for more details see section [How to use HPX applications with PBS](#)), specifying dedicated command line options for single localities may be desirable. For this reason all of the command line options that have the general format `--hpx:<some_key>` can be used in a more general form: `--hpx:<N>:<some_key>`, where <N> is the number of the *locality* this command line option will be applied to; all other localities will simply ignore the option. For instance, the following PBS script passes the option `--hpx:pu-offset=4` to the *locality* '1' only.

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE`
```

**Caution:** If the first application specific argument (inside \$APP\_OPTIONS) is a non-option (i.e., does not start with a - or a --), then it must be placed before the option `--hpx:nodes`, which, in this case, should be the last option on the command line.

Alternatively, use the option `--hpx:endnodes` to explicitly mark the end of the list of node names:

```
$ pbsdsh -u $APP_PATH --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE` --
→hpx:endnodes $APP_OPTIONS
```

## More details about *HPX* command line options

This section documents the following list of the command line options in more detail:

- *The command line option* `--hpx:bind`

### The command line option `--hpx:bind`

This command line option allows one to specify the required affinity of the *HPX* worker threads to the underlying processing units. As a result the worker threads will run only on the processing units identified by the corresponding bind specification. The affinity settings are to be specified using `--hpx:bind=<BINDINGS>`, where <BINDINGS> have to be formatted as described below.

In addition to the syntax described below, one can use `--hpx:bind=none` to disable all binding of any threads to a particular core. This is mostly supported for debugging purposes.

The specified affinities refer to specific regions within a machine hardware topology. In order to understand the hardware topology of a particular machine, it may be useful to run the `lstopo` tool, which is part of Portable Hardware

Locality (HWLOC), to see the reported topology tree. Seeing and understanding a topology tree will definitely help in understanding the concepts that are discussed below.

Affinities can be specified using hwloc tuples. Tuples of hwloc *objects* and associated *indexes* can be specified in the form `object:index`, `object:index-index` or `object:index,...,index`. Hwloc objects represent types of mapped items in a topology tree. Possible values for objects are `socket`, `numanode`, `core` and `pu` (processing unit). Indexes are non-negative integers that specify a unique physical object in a topology tree using its logical sequence number.

Chaining multiple tuples together in the more general form `object1:index1[.object2:index2[...]]` is permissible. While the first tuple's object may appear anywhere in the topology, the Nth tuple's object must have a shallower topology depth than the (N+1)th tuple's object. Put simply: as you move right in a tuple chain, objects must go deeper in the topology tree. Indexes specified in chained tuples are relative to the scope of the parent object. For example, `socket:0.core:1` refers to the second core in the first socket (all indices are zero based).

Multiple affinities can be specified using several `--hpx:bind` command line options or by appending several affinities separated by a '`;`'. By default, if multiple affinities are specified, they are added.

`"all"` is a special affinity consisting in the entire current topology.

---

**Note:** All “names” in an affinity specification, such as `thread`, `socket`, `numanode`, `pu` or `all`, can be abbreviated. Thus, the affinity specification `threads:0-3=socket:0.core:1.pu:1` is fully equivalent to its shortened form `t:0-3=s:0.c:1.p:1`.

---

Here is a full grammar describing the possible format of mappings:

```

mappings      ::= distribution | mapping (";" mapping)*
distribution   ::= "compact" | "scatter" | "balanced" | "numa-balanced"
mapping        ::= thread_spec "=" pu_specs
thread_spec    ::= "thread:" range_specs
pu_specs       ::= pu_spec ("." pu_spec)*
pu_spec        ::= type ":" range_specs | "~" pu_spec
range_specs    ::= range_spec ("," range_spec)*
range_spec     ::= int | int "-" int | "all"
type           ::= "socket" | "numanode" | "core" | "pu"

```

The following example assumes a system with at least 4 cores, where each core has more than 1 processing unit (hardware threads). Running `hello_world_distributed` with 4 OS threads (on 4 processing units), where each of those threads is bound to the first processing unit of each of the cores, can be achieved by invoking:

```
$ hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0
```

Here, `thread:0-3` specifies the OS threads used to define affinity bindings, and `core:0-3.pu:0` defines that for each of the cores (`core:0-3`) only their first processing unit `pu:0` should be used.

---

**Note:** The command line option `--hpx:print-bind` can be used to print the bitmasks generated from the affinity mappings as specified with `--hpx:bind`. For instance, on a system with hyperthreading enabled (i.e. 2 processing units per core), the command line:

```
$ hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0 --hpx:print-bind
```

will cause this output to be printed:

```
0: PU L#0(P#0), Core L#0, Socket L#0, Node L#0(P#0)
1: PU L#2(P#2), Core L#1, Socket L#0, Node L#0(P#0)
2: PU L#4(P#4), Core L#2, Socket L#0, Node L#0(P#0)
3: PU L#6(P#6), Core L#3, Socket L#0, Node L#0(P#0)
```

where each bit in the bitmasks corresponds to a processing unit the listed worker thread will be bound to run on.

The difference between the four possible predefined distribution schemes (`compact`, `scatter`, `balanced` and `numa-balanced`) is best explained with an example. Imagine that we have a system with 4 cores and 4 hardware threads per core on 2 sockets. If we place 8 threads the assignments produced by the `compact`, `scatter`, `balanced` and `numa-balanced` types are shown in the figure below. Notice that `compact` does not fully utilize all the cores in the system. For this reason it is recommended that applications are run using the `scatter` or `balanced/numa-balanced` options in most cases.

Fig. 2.7: Schematic of thread affinity type distributions.

In addition to the predefined distributions it is possible to restrict the resources used by *HPX* to the process CPU

mask. The CPU mask is typically set by e.g. MPI<sup>42</sup> and batch environments. Using the command line option `--hpx:use-process-mask` makes HPX act as if only the processing units in the CPU mask are available for use by HPX. The number of threads is automatically determined from the CPU mask. The number of threads can still be changed manually using this option, but only to a number less than or equal to the number of processing units in the CPU mask. The option `--hpx:print-bind` is useful in conjunction with `--hpx:use-process-mask` to make sure threads are placed as expected.

### 2.3.8 Writing single-node HPX applications

HPX is a C++ Standard Library for Concurrency and Parallelism. This means that it implements all of the corresponding facilities as defined by the C++ Standard. Additionally, HPX implements functionalities proposed as part of the ongoing C++ standardization process. This section focuses on the features available in HPX for parallel and concurrent computation on a single node, although many of the features presented here are also implemented to work in the distributed case.

#### Using LCOs

*Lightweight Control Objects* (LCOs) provide synchronization for HPX applications. Most of them are familiar from other frameworks, but a few of them work in slightly different ways adapted to HPX. The following synchronization objects are available in HPX:

1. `future`
2. `queue`
3. `object_semaphore`
4. `barrier`

#### Channels

Channels combine communication (the exchange of a value) with synchronization (guaranteeing that two calculations (tasks) are in a known state). A channel can transport any number of values of a given type from a sender to a receiver:

```
hpx::lcos::local::channel<int> c;
hpx::future<int> f = c.get();
HPX_ASSERT(!f.is_ready());
c.set(42);
HPX_ASSERT(f.is_ready());
std::cout << f.get() << std::endl;
```

Channels can be handed to another thread (or in case of channel components, to other localities), thus establishing a communication channel between two independent places in the program:

```
void do_something(hpx::lcos::local::receive_channel<int> c,
                  hpx::lcos::local::send_channel<> done)
{
    // prints 43
    std::cout << c.get(hpx::launch::sync) << std::endl;
    // signal back
    done.set();
```

(continues on next page)

<sup>42</sup> [https://en.wikipedia.org/wiki/Message\\_Passing\\_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

(continued from previous page)

```

}

void send_receive_channel()
{
    hpx::lcos::local::channel<int> c;
    hpx::lcos::local::channel<> done;

    hpx::apply(&do_something, c, done);

    // send some value
    c.set(43);
    // wait for thread to be done
    done.get().wait();
}

```

Note how `hpx::lcos::local::channel::get` without any arguments returns a future which is ready when a value has been set on the channel. The launch policy `hpx::launch::sync` can be used to make `hpx::lcos::local::channel::get` block until a value is set and return the value directly.

A channel component is created on one *locality* and can be sent to another *locality* using an action. This example also demonstrates how a channel can be used as a range of values:

```

// channel components need to be registered for each used type (not needed
// for hpx::lcos::local::channel)
HPX_REGISTER_CHANNEL(double)

void channel_sender(hpx::lcos::channel<double> c)
{
    for (double d : c)
        hpx::cout << d << std::endl;
}
HPX_PLAIN_ACTION(channel_sender)

void channel()
{
    // create the channel on this locality
    hpx::lcos::channel<double> c(hpx::find_here());

    // pass the channel to a (possibly remote invoked) action
    hpx::apply(channel_sender_action(), hpx::find_here(), c);

    // send some values to the receiver
    std::vector<double> v = {1.2, 3.4, 5.0};
    for (double d : v)
        c.set(d);

    // explicitly close the communication channel (implicit at destruction)
    c.close();
}

```

## Composable guards

Composable guards operate in a manner similar to locks, but are applied only to asynchronous functions. The guard (or guards) is automatically locked at the beginning of a specified task and automatically unlocked at the end. Because guards are never added to an existing task's execution context, the calling of guards is freely composable and can never deadlock.

To call an application with a single guard, simply declare the guard and call run\_guarded() with a function (task):

```
hpx::lcos::local::guard gu;
run_guarded(gu, task);
```

If a single method needs to run with multiple guards, use a guard set:

```
boost::shared<hpx::lcos::local::guard> gu1(new hpx::lcos::local::guard());
boost::shared<hpx::lcos::local::guard> gu2(new hpx::lcos::local::guard());
gs.add(*gu1);
gs.add(*gu2);
run_guarded(gs, task);
```

Guards use two atomic operations (which are not called repeatedly) to manage what they do, so overhead should be extremely low. The following guards are available in *HPX*:

1. conditional\_trigger
2. counting\_semaphore
3. dataflow
4. event
5. mutex
6. once
7. recursive\_mutex
8. spinlock
9. spinlock\_no\_backoff
10. trigger

## Extended facilities for futures

Concurrency is about both decomposing and composing the program from the parts that work well individually and together. It is in the composition of connected and multicore components where today's C++ libraries are still lacking.

The functionality of `std::future` offers a partial solution. It allows for the separation of the initiation of an operation and the act of waiting for its result; however, the act of waiting is synchronous. In communication-intensive code this act of waiting can be unpredictable, inefficient and simply frustrating. The example below illustrates a possible synchronous wait using futures:

```
#include <future>
using namespace std;
int main()
{
    future<int> f = async([]() { return 123; });
}
```

(continues on next page)

(continued from previous page)

```
int result = f.get(); // might block
}
```

For this reason, *HPX* implements a set of extensions to `std::future` (as proposed by [\\_cpp11\\_n4107\\_](#)). This proposal introduces the following key asynchronous operations to `hpx::future`, `hpx::shared_future` and `hpx::async`, which enhance and enrich these facilities.

Table 2.11: Facilities extending `std::future`

Facility	Description
<code>hpx::future</code>	Asynchronous programming, it is very common for one asynchronous operation, on completion, to invoke a second operation and pass data to it. The current C++ standard does not allow one to register a continuation to a future. With <code>then</code> , instead of waiting for the result, a continuation is “attached” to the asynchronous operation, which is invoked when the result is ready. Continuations registered using <code>then</code> function will help to avoid blocking waits or wasting threads on polling, greatly improving the responsiveness and scalability of an application.
unwrapping constructor for <code>hpx::future</code>	In some scenarios, you might want to create a future that returns another future, resulting in nested futures. Although it is possible to write code to unwrap the outer future and retrieve the nested future and its result, such code is not easy to write because users must handle exceptions and it may cause a blocking call. Unwrapping can allow users to mitigate this problem by doing an asynchronous call to unwrap the outermost future.
<code>hpx::future</code>	There are situations where a <code>get()</code> call on a future may not be a blocking call, or is only a blocking call under certain circumstances. This function gives the ability to test for early completion and allows us to avoid associating a continuation, which needs to be scheduled with some non-trivial overhead and near-certain loss of cache efficiency.
<code>hpx::make_ready_future</code>	Some functions may know the value at the point of construction. In these cases the value is immediately available, but needs to be returned as a future. By using <code>hpx::make_ready_future</code> a future can be created that holds a pre-computed result in its shared state. In the current standard it is non-trivial to create a future directly from a value. First a promise must be created, then the promise is set, and lastly the future is retrieved from the promise. This can now be done with one operation.

The standard also omits the ability to compose multiple futures. This is a common pattern that is ubiquitous in other asynchronous frameworks and is absolutely necessary in order to make C++ a powerful asynchronous programming language. Not including these functions is synonymous to Boolean algebra without AND/OR.

In addition to the extensions proposed by [N4313<sup>44</sup>](#), *HPX* adds functions allowing users to compose several futures in a more flexible way.

<sup>44</sup> <http://wg21.link/n4313>

Table 2.12: Facilities for composing `hpx::futures`

Facility	Description	Comment
<code>hpx::when_any</code> , <code>hpx::when_any_n</code>	Asynchronously wait for at least one of multiple future or shared_future objects to finish.	N4313 <sup>45</sup> , ..._n versions are HPX only
<code>hpx::wait_any</code> , <code>hpx::wait_any_n</code>	Synchronously wait for at least one of multiple future or shared_future objects to finish.	HPX only
<code>hpx::when_all</code> , <code>hpx::when_all_n</code>	Asynchronously wait for all future and shared_future objects to finish.	N4313 <sup>46</sup> , ..._n versions are HPX only
<code>hpx::wait_all</code> , <code>hpx::wait_all_n</code>	Synchronously wait for all future and shared_future objects to finish.	HPX only
<code>hpx::when_some</code> , <code>hpx::when_some_n</code>	Asynchronously wait for multiple future and shared_future objects to finish.	HPX only
<code>hpx::wait_some</code> , <code>hpx::wait_some_n</code>	Synchronously wait for multiple future and shared_future objects to finish.	HPX only
<code>hpx::when_each</code>	Asynchronously wait for multiple future and shared_future objects to finish and call a function for each of the future objects as soon as it becomes ready.	HPX only
<code>hpx::wait_each</code> , <code>hpx::wait_each_n</code>	Synchronously wait for multiple future and shared_future objects to finish and call a function for each of the future objects as soon as it becomes ready.	HPX only

## High level parallel facilities

In preparation for the upcoming C++ Standards, there are currently several proposals targeting different facilities supporting parallel programming. *HPX* implements (and extends) some of those proposals. This is well aligned with our strategy to align the APIs exposed from *HPX* with current and future C++ Standards.

At this point, *HPX* implements several of the C++ Standardization working papers, most notably N4409<sup>47</sup> (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411<sup>48</sup> (Task Blocks), and N4406<sup>49</sup> (Parallel Algorithms Need Executors).

## Using parallel algorithms

A parallel algorithm is a function template described by this document which is declared in the (inline) namespace `hpx::parallel::v1`.

---

**Note:** For compilers that do not support inline namespaces, all of the namespace `v1` is imported into the namespace `hpx::parallel`. The effect is similar to what inline namespaces would do, namely all names defined in `hpx::parallel::v1` are accessible from the namespace `hpx::parallel` as well.

---

All parallel algorithms are very similar in semantics to their sequential counterparts (as defined in the namespace `std`) with an additional formal template parameter named `ExecutionPolicy`. The execution policy is generally passed as

<sup>45</sup> <http://wg21.link/n4313>

<sup>46</sup> <http://wg21.link/n4313>

<sup>47</sup> <http://wg21.link/n4409>

<sup>48</sup> <http://wg21.link/n4411>

<sup>49</sup> <http://wg21.link/n4406>

the first argument to any of the parallel algorithms and describes the manner in which the execution of these algorithms may be parallelized and the manner in which they apply user-provided function objects.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::sequenced_policy` or `hpx::execution::sequenced_task_policy` execute in sequential order. For `hpx::execution::sequenced_policy` the execution happens in the calling thread.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::parallel_policy` or `hpx::execution::parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and are indeterminately sequenced within each thread.

---

**Important:** It is the caller's responsibility to ensure correctness, such as making sure that the invocation does not introduce data races or deadlocks.

---

The applications of function objects in parallel algorithms invoked with an execution policy of type `hpx::execution::parallel_unsequenced_policy` is, in HPX, equivalent to the use of the execution policy `hpx::execution::parallel_policy`.

Algorithms invoked with an execution policy object of type `hpx::parallel::v1::execution_policy` execute internally as if invoked with the contained execution policy object. No exception is thrown when an `hpx::parallel::v1::execution_policy` contains an execution policy of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` (which normally turn the algorithm into its asynchronous version). In this case the execution is semantically equivalent to the case of passing a `hpx::execution::sequenced_policy` or `hpx::execution::parallel_policy` contained in the `hpx::parallel::v1::execution_policy` object respectively.

## Parallel exceptions

During the execution of a standard parallel algorithm, if temporary memory resources are required by any of the algorithms and no memory is available, the algorithm throws a `std::bad_alloc` exception.

During the execution of any of the parallel algorithms, if the application of a function object terminates with an uncaught exception, the behavior of the program is determined by the type of execution policy used to invoke the algorithm:

- If the execution policy object is of type `hpx::execution::parallel_unsequenced_policy`, `hpx::terminate` shall be called.
- If the execution policy object is of type `hpx::execution::sequenced_policy`, `hpx::execution::sequenced_task_policy`, `hpx::execution::parallel_policy`, or `hpx::execution::parallel_task_policy`, the execution of the algorithm terminates with an `hpx::exception_list` exception. All uncaught exceptions thrown during the application of user-provided function objects shall be contained in the `hpx::exception_list`.

For example, the number of invocations of the user-provided function object in `for_each` is unspecified. When `hpx::parallel::v1::for_each` is executed sequentially, only one exception will be contained in the `hpx::exception_list` object.

These guarantees imply that, unless the algorithm has failed to allocate memory and terminated with `std::bad_alloc`, all exceptions thrown during the execution of the algorithm are communicated to the caller. It is unspecified whether an algorithm implementation will “forge ahead” after encountering and capturing a user exception.

The algorithm may terminate with the `std::bad_alloc` exception even if one or more user-provided function objects have terminated with an exception. For example, this can happen when an algorithm fails to allocate memory while creating or adding elements to the `hpx::exception_list` object.

## Parallel algorithms

*HPX* provides implementations of the following parallel algorithms:

Table 2.13: Non-modifying parallel algorithms (in header: &lt;hpx/algorithm.hpp&gt;)

Name	Description	In header	Algorithm page at cp-preference.com
<code>hpx::adjacent_find</code>	Computes the differences between adjacent elements in a range.	<hpx/algorithm.hpp>	<a href="#">adjacent_find<sup>50</sup></a>
<code>hpx::all_of</code>	Checks if a predicate is <code>true</code> for all of the elements in a range.	<hpx/algorithm.hpp>	<a href="#">all_any_none_of<sup>51</sup></a>
<code>hpx::any_of</code>	Checks if a predicate is <code>true</code> for any of the elements in a range.	<hpx/algorithm.hpp>	<a href="#">all_any_none_of<sup>52</sup></a>
<code>hpx::count</code>	Returns the number of elements equal to a given value.	<hpx/algorithm.hpp>	<a href="#">count<sup>53</sup></a>
<code>hpx::count_if</code>	Returns the number of elements satisfying a specific criteria.	<hpx/algorithm.hpp>	<a href="#">count_if<sup>54</sup></a>
<code>hpx::equal</code>	Determines if two sets of elements are the same.	<hpx/algorithm.hpp>	<a href="#">equal<sup>55</sup></a>
<code>hpx::find</code>	Finds the first element equal to a given value.	<hpx/algorithm.hpp>	<a href="#">find<sup>56</sup></a>
<code>hpx::find_end</code>	Finds the last sequence of elements in a certain range.	<hpx/algorithm.hpp>	<a href="#">find_end<sup>57</sup></a>
<code>hpx::find_first_of</code>	Searches for any one of a set of elements.	<hpx/algorithm.hpp>	<a href="#">find_first_of<sup>58</sup></a>
<code>hpx::find_if</code>	Finds the first element satisfying a specific criteria.	<hpx/algorithm.hpp>	<a href="#">find_if<sup>59</sup></a>
<code>hpx::find_if_not</code>	Finds the first element not satisfying a specific criteria.	<hpx/algorithm.hpp>	<a href="#">find_if_not<sup>60</sup></a>
<code>hpx::for_each</code>	Applies a function to a range of elements.	<hpx/algorithm.hpp>	<a href="#">for_each<sup>61</sup></a>
<code>hpx::for_each_n</code>	Applies a function to a number of elements.	<hpx/algorithm.hpp>	<a href="#">for_each_n<sup>62</sup></a>
<code>hpx::lexicographical_compare</code>	Checks if a range of values is lexicographically less than another range of values.	<hpx/algorithm.hpp>	<a href="#">lexicographical_compare<sup>63</sup></a>
<code>hpx::parallel::v1::mismatch</code>	Finds the first position where two ranges differ.	<hpx/algorithm.hpp>	<a href="#">mismatch<sup>64</sup></a>
<code>hpx::none_of</code>	Checks if a predicate is <code>true</code> for none of the elements in a range.	<hpx/algorithm.hpp>	<a href="#">all_any_none_of<sup>65</sup></a>
<code>hpx::search</code>	Searches for a range of elements.	<hpx/algorithm.hpp>	<a href="#">search<sup>66</sup></a>
<code>hpx::search_n</code>	Searches for a number consecutive copies of an element in a range.	<hpx/algorithm.hpp>	<a href="#">search_n<sup>67</sup></a>

Table 2.14: Modifying parallel algorithms (In Header:  
`<hpx/algorithm.hpp>`)

Name	Description	In header	Algorithm page at cppreference.com
<code>hpx::copy</code>	Copies a range of elements to a new location.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>exclusive_scan</code> <sup>68</sup>
<code>hpx::copy_n</code>	Copies a number of elements to a new location.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>copy_n</code> <sup>69</sup>
<code>hpx::copy_if</code>	Copies the elements from a range to a new location for which the given predicate is <code>true</code>	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>copy</code> <sup>70</sup>
<code>hpx::move</code>	Moves a range of elements to a new location.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>move</code> <sup>71</sup>
<code>hpx::fill</code>	Assigns a range of elements a certain value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>fill</code> <sup>72</sup>
<code>hpx::fill_n</code>	Assigns a value to a number of elements.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>fill_n</code> <sup>73</sup>
<code>hpx::generate</code>	Saves the result of a function in a range.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>generate</code> <sup>74</sup>
<code>hpx::generate_n</code>	Saves the result of N applications of a function.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>generate_n</code> <sup>75</sup>
<code>hpx::remove</code>	Removes the elements from a range that are equal to the given value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>remove</code> <sup>76</sup>
<code>hpx::remove_if</code>	Removes the elements from a range that are equal to the given predicate is <code>false</code>	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>remove</code> <sup>77</sup>
<code>hpx::remove_copy</code>	Copies the elements from a range to a new location that are not equal to the given value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>remove_copy</code> <sup>78</sup>
<code>hpx::remove_copy_if</code>	Copies the elements from a range to a new location for which the given predicate is <code>false</code>	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>remove_copy</code> <sup>79</sup>
<code>hpx::replace</code>	Replaces all values satisfying specific criteria with another value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>replace</code> <sup>80</sup>
<code>hpx::replace_if</code>	Replaces all values satisfying specific criteria with another value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>replace</code> <sup>81</sup>
<code>hpx::replace_copy</code>	Copies a range, replacing elements satisfying specific criteria with another value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>replace_copy</code> <sup>82</sup>
<code>hpx::replace_copy_if</code>	Copies a range, replacing elements satisfying specific criteria with another value.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>replace_copy</code> <sup>83</sup>
<code>hpx::reverse</code>	Reverses the order elements in a range.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>reverse</code> <sup>84</sup>
<b>118</b> <code>hpx::reverse_copy</code>	Creates a copy of a range that is reversed.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<b>Chapter 2. What's so special about HPX?</b> <code>reverse_copy</code> <sup>85</sup>
<code>hpx::parallel::v1::rotate</code>	Rotates the order of elements in a range.	<code>&lt;hpx/algorithm.hpp&gt;</code>	<code>rotate</code> <sup>86</sup>

Table 2.15: Set operations on sorted sequences (In Header:  
*<hpx/algorithm.hpp>*)

Name	Description	In header	Algorithm page at cp-preference.com
<i>hpx::merge</i>	Merges two sorted ranges.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">merge<sup>94</sup></a>
<i>hpx::inplace_merge</i>	Merges two ordered ranges in-place.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">inplace_merge<sup>95</sup></a>
<i>hpx::includes</i>	Returns true if one set is a subset of another.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">includes<sup>96</sup></a>
<i>hpx::set_difference</i>	Computes the difference between two sets.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">set_difference<sup>97</sup></a>
<i>hpx::set_intersection</i>	Computes the intersection of two sets.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">set_intersection<sup>98</sup></a>
<i>hpx::set_symmetric_difference</i>	Computes the symmetric difference between two sets.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">set_symmetric_difference<sup>99</sup></a>
<i>hpx::set_union</i>	Computes the union of two sets.	<i>&lt;hpx/algorithm.hpp&gt;</i>	<a href="#">set_union<sup>100</sup></a>

Table 2.20: Index-based for-loops (In Header: *<hpx/algorithm.hpp>*)

Name	Description	In header
<code>hpx::experimental::for_loop</code>	Implements loop functionality over a range specified by integral or iterator bounds.	<code>&lt;hpx/algorithm.hpp&gt;</code>
<code>hpx::experimental::for_loop</code>	Implements loop functionality over a range specified by integral or iterator bounds.	<code>&lt;hpx/algorithm.hpp&gt;</code>
<code>hpx::experimental::for_loop</code>	Implements loop functionality over a range specified by integral or iterator bounds.	<code>&lt;hpx/algorithm.hpp&gt;</code>
<code>hpx::experimental::for_loop</code>	Implements loop functionality over a range specified by integral or iterator bounds.	<code>&lt;hpx/algorithm.hpp&gt;</code>

## Executor parameters and executor parameter traits

HPX introduces the notion of execution parameters and execution parameter traits. At this point, the only parameter that can be customized is the size of the chunks of work executed on a single HPX thread (such as the number of loop iterations combined to run as a single task).

An executor parameter object is responsible for exposing the calculation of the size of the chunks scheduled. It abstracts the (potentially platform-specific) algorithms of determining those chunk sizes.

The way executor parameters are implemented is aligned with the way executors are implemented. All functionalities of concrete executor parameter types are exposed and accessible through a corresponding `hpx::parallel::executor_parameter_traits` type.

With `executor_parameter_traits`, clients access all types of executor parameters uniformly:

```
std::size_t chunk_size =
    executor_parameter_traits<my_parameter_t>::get_chunk_size(my_parameter,
        my_executor, []() { return 0; }, num_tasks);
```

This call synchronously retrieves the size of a single chunk of loop iterations (or similar) to combine for execution on a single HPX thread if the overall number of tasks to schedule is given by `num_tasks`. The lambda function exposes a means of test-probing the execution of a single iteration for performance measurement purposes. The execution parameter type might dynamically determine the execution time of one or more tasks in order to calculate the chunk size; see `hpx::execution::auto_chunk_size` for an example of this executor parameter type.

Other functions in the interface exist to discover whether an executor parameter type should be invoked once (i.e., it returns a static chunk size; see `hpx::execution::static_chunk_size`) or whether it should be invoked for each scheduled chunk of work (i.e., it returns a variable chunk size; for an example, see `hpx::execution::guided_chunk_size`).

Although this interface appears to require executor parameter type authors to implement all different basic operations, none are required. In practice, all operations have sensible defaults. However, some executor parameter types will naturally specialize all operations for maximum efficiency.

HPX implements the following executor parameter types:

- `hpx::execution::auto_chunk_size`: Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameter type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

- *hpx::execution::static\_chunk\_size*: Loop iterations are divided into pieces of a given size and then assigned to threads. If the size is not specified, the iterations are, if possible, evenly divided contiguously among the threads. This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.
- *hpx::execution::dynamic\_chunk\_size*: Loop iterations are divided into pieces of a given size and then dynamically scheduled among the cores; when a core finishes one chunk, it is dynamically assigned another. If the size is not specified, the default chunk size is 1. This executor parameter type is equivalent to OpenMP's DYNAMIC scheduling directive.
- *hpx::execution::guided\_chunk\_size*: Iterations are dynamically assigned to cores in blocks as cores request them until no blocks remain to be assigned. This is similar to *dynamic\_chunk\_size* except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to *number\_of\_iterations / number\_of\_cores*. Subsequent blocks are proportional to *number\_of\_iterations\_remaining / number\_of\_cores*. The optional chunk size parameter defines the minimum block size. The default minimal chunk size is 1. This executor parameter type is equivalent to OpenMP's GUIDED scheduling directive.

## Using task blocks

The `define_task_block`, `run` and the `wait` functions implemented based on N4411<sup>126</sup> are based on the `task_block` concept that is a part of the common subset of the Microsoft Parallel Patterns Library (PPL)<sup>127</sup> and the Intel Threading Building Blocks (TBB)<sup>128</sup> libraries.

These implementations adopt a simpler syntax than exposed by those libraries—one that is influenced by language-based concepts, such as `spawn` and `sync` from Cilk++<sup>129</sup> and `async` and `finish` from X10<sup>130</sup>. They improve on existing practice in the following ways:

- The exception handling model is simplified and more consistent with normal C++ exceptions.
- Most violations of strict fork-join parallelism can be enforced at compile time (with compiler assistance, in some cases).
- The syntax allows scheduling approaches other than child stealing.

Consider an example of a parallel traversal of a tree, where a user-provided function `compute` is applied to each node of the tree, returning the sum of the results:

```
template <typename Func>
int traverse(node& n, Func && compute)
{
    int left = 0, right = 0;
    define_task_block(
        [&](task_block<>& tr) {
            if (n.left)
                tr.run([&] { left = traverse(*n.left, compute); });
            if (n.right)
                tr.run([&] { right = traverse(*n.right, compute); });
        });

    return compute(n) + left + right;
}
```

<sup>126</sup> <http://wg21.link/n4411>

<sup>127</sup> <https://msdn.microsoft.com/en-us/library/dd492418.aspx>

<sup>128</sup> <https://www.threadingbuildingblocks.org/>

<sup>129</sup> <https://software.intel.com/en-us/articles/intel-cilk-plus/>

<sup>130</sup> <https://x10-lang.org/>

The example above demonstrates the use of two of the functions, `hpx::parallel::define_task_block` and the `hpx::parallel::task_block::run` member function of a `hpx::parallel::task_block`.

The `task_block` function delineates a region in a program code potentially containing invocations of threads spawned by the `run` member function of the `task_block` class. The `run` function spawns an *HPX* thread, a unit of work that is allowed to execute in parallel with respect to the caller. Any parallel tasks spawned by `run` within the task block are joined back to a single thread of execution at the end of the `define_task_block`. `run` takes a user-provided function object `f` and starts it asynchronously—i.e., it may return before the execution of `f` completes. The *HPX* scheduler may choose to run `f` immediately or delay running `f` until compute resources become available.

A `task_block` can be constructed only by `define_task_block` because it has no public constructors. Thus, `run` can be invoked directly or indirectly only from a user-provided function passed to `define_task_block`:

```
void g();

void f(task_block<>& tr)
{
    tr.run(g);           // OK, invoked from within task_block in h
}

void h()
{
    define_task_block(f);
}

int main()
{
    task_block<> tr;    // Error: no public constructor
    tr.run(g);           // No way to call run outside of a define_task_block
    return 0;
}
```

## Extensions for task blocks

### Using execution policies with task blocks

*HPX* implements some extensions for `task_block` beyond the actual standards proposal N4411<sup>131</sup>. The main addition is that a `task_block` can be invoked with an execution policy as its first argument, very similar to the parallel algorithms.

An execution policy is an object that expresses the requirements on the ordering of functions invoked as a consequence of the invocation of a task block. Enabling passing an execution policy to `define_task_block` gives the user control over the amount of parallelism employed by the created `task_block`. In the following example the use of an explicit `par` execution policy makes the user's intent explicit:

```
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par,           // execution::parallel_policy
```

(continues on next page)

<sup>131</sup> <http://wg21.link/n4411>

(continued from previous page)

```
[&](task_block<>& tb) {
    if (n->left)
        tb.run([&] { left = traverse(n->left, compute); });
    if (n->right)
        tb.run([&] { right = traverse(n->right, compute); });
};

return compute(n) + left + right;
}
```

This also causes the `hpx::parallel::v2::task_block` object to be a template in our implementation. The template argument is the type of the execution policy used to create the task block. The template argument defaults to `hpx::execution::parallel_policy`.

HPX still supports calling `hpx::parallel::v2::define_task_block` without an explicit execution policy. In this case the task block will run using the `hpx::execution::parallel_policy`.

HPX also adds the ability to access the execution policy that was used to create a given `task_block`.

## Using executors to run tasks

Often, users want to be able to not only define an execution policy to use by default for all spawned tasks inside the task block, but also to customize the execution context for one of the tasks executed by `task_block::run`. Adding an optionally passed executor instance to that function enables this use case:

```
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par, // execution::parallel_policy
        [&](auto& tb) {
            if (n->left)
            {
                // use explicitly specified executor to run this task
                tb.run(my_executor(), [&] { left = traverse(n->left, compute); });
            }
            if (n->right)
            {
                // use the executor associated with the par execution policy
                tb.run([&] { right = traverse(n->right, compute); });
            }
        });
    return compute(n) + left + right;
}
```

HPX still supports calling `hpx::parallel::v2::task_block::run` without an explicit executor object. In this case the task will be run using the executor associated with the execution policy that was used to call `hpx::parallel::v2::define_task_block`.

## 2.3.9 Writing distributed HPX applications

This section focuses on the features of *HPX* needed to write distributed applications, namely the *Active Global Address Space* (*AGAS*), remotely executable functions (i.e., *actions*), and distributed objects (i.e., *components*).

### Global names

*HPX* implements an *Active Global Address Space* (*AGAS*) which exposes a single uniform address space spanning all localities an application runs on. *AGAS* is a fundamental component of the *ParalleX* execution model. Conceptually, there is no rigid demarcation of local or global memory in *AGAS*; all available memory is a part of the same address space. *AGAS* enables named objects to be moved (migrated) across localities without having to change the object's name; i.e., no references to migrated objects have to be ever updated. This feature has significance for dynamic load balancing and in applications where the workflow is highly dynamic, allowing work to be migrated from heavily loaded nodes to less loaded nodes. In addition, immutability of names ensures that *AGAS* does not have to keep extra indirections ("bread crumbs") when objects move, hence, minimizing complexity of code management for system developers as well as minimizing overheads in maintaining and managing aliases.

The *AGAS* implementation in *HPX* does not automatically expose every local address to the global address space. It is the responsibility of the programmer to explicitly define which of the objects have to be globally visible and which of the objects are purely local.

In *HPX* global addresses (global names) are represented using the `hpx::id_type` data type. This data type is conceptually very similar to `void*` pointers as it does not expose any type information of the object it is referring to.

The only predefined global addresses are assigned to all localities. The following *HPX* API functions allow one to retrieve the global addresses of localities:

- `hpx::find_here`: retrieves the global address of the *locality* this function is called on.
- `hpx::find_all_localities`: retrieves the global addresses of all localities available to this application (including the *locality* the function is being called on).
- `hpx::find_remote_localities`: retrieves the global addresses of all remote localities available to this application (not including the *locality* the function is being called on).
- `hpx::get_num_localities`: retrieves the number of localities available to this application.
- `hpx::find_locality`: retrieves the global address of any *locality* supporting the given component type.
- `hpx::get_colocation_id`: retrieves the global address of the *locality* currently hosting the object with the given global address.

Additionally, the global addresses of localities can be used to create new instances of components using the following *HPX* API function:

- `hpx::components::new_`: Creates a new instance of the given Component type on the specified *locality*.

---

**Note:** *HPX* does not expose any functionality to delete component instances. All global addresses (as represented using `hpx::id_type`) are automatically garbage collected. When the last (global) reference to a particular component instance goes out of scope, the corresponding component instance is automatically deleted.

## Applying actions

### Action type definition

Actions are special types used to describe possibly remote operations. For every global function and every member function which has to be invoked distantly, a special type must be defined. For any global function the special macro `HPX_PLAIN_ACTION` can be used to define the action type. Here is an example demonstrating this:

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // This will define the action type 'some_global_action' which represents
    // the function 'app::some_global_function'.
    HPX_PLAIN_ACTION(app::some_global_function, some_global_action);
```

---

**Important:** The macro `HPX_PLAIN_ACTION` has to be placed in global namespace, even if the wrapped function is located in some other namespace. The newly defined action type is placed in the global namespace as well.

---

If the action type should be defined somewhere not in global namespace, the action type definition has to be split into two macro invocations (`HPX_DEFINE_PLAIN_ACTION` and `HPX_REGISTER_ACTION`) as shown in the next example:

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // On conforming compilers the following macro expands to:
    //
    //     typedef hpx::actions::make_action<
    //         decltype(&some_global_function), &some_global_function
    //     >::type some_global_action;
    //
    // This will define the action type 'some_global_action' which represents
    // the function 'some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}

// The following macro expands to a series of definitions of global objects
// which are needed for proper serialization and initialization support
// enabling the remote invocation of the function ``some_global_function``
HPX_REGISTER_ACTION(app::some_global_action, app_some_global_action);
```

The shown code defines an action type `some_global_action` inside the namespace `app`.

---

**Important:** If the action type definition is split between two macros as shown above, the name of the action type to

---

create has to be the same for both macro invocations (here `some_global_action`).

---

**Important:** The second argument passed to `HPX_REGISTER_ACTION` (`app_some_global_action`) has to comprise a globally unique C++ identifier representing the action. This is used for serialization purposes.

---

For member functions of objects which have been registered with AGAS (e.g., ‘components’), a different registration macro `HPX_DEFINE_COMPONENT_ACTION` has to be utilized. Any component needs to be declared in a header file and have some special support macros defined in a source file. Here is an example demonstrating this. The first snippet has to go into the header file:

```
namespace app
{
    struct some_component
        : hpx::components::component_base<some_component>
    {
        int some_member_function(std::string s)
        {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function,
            some_member_action);
    };
}

// Note: The second argument to the macro below has to be systemwide-unique
//        C++ identifiers
HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_component_
    ↪some_action);
```

The next snippet belongs in a source file (e.g., the main application source file) in the simplest case:

```
typedef hpx::components::component<app::some_component> component_type;
typedef app::some_component some_component;

HPX_REGISTER_COMPONENT(component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation above
typedef some_component::some_member_action some_component_some_action;
HPX_REGISTER_ACTION(some_component_some_action);
```

While these macro invocations are a bit more complex than those for simple global functions, they should still be manageable.

The most important macro invocation is the `HPX_DEFINE_COMPONENT_ACTION` in the header file as this defines the action type we need to invoke the member function. For a complete example of a simple component action see `component_in_executable.cpp`.

## Action invocation

The process of invoking a global function (or a member function of an object) with the help of the associated action is called ‘applying the action’. Actions can have arguments, which will be supplied while the action is applied. At the minimum, one parameter is required to apply any action - the id of the *locality* the associated function should be invoked on (for global functions), or the id of the component instance (for member functions). Generally, *HPX* provides several ways to apply an action, all of which are described in the following sections.

Generally, *HPX* actions are very similar to ‘normal’ C++ functions except that actions can be invoked remotely. Fig. 2.8 below shows an overview of the main API exposed by *HPX*. This shows the function invocation syntax as defined by the C++ language (dark gray), the additional invocation syntax as provided through C++ Standard Library features (medium gray), and the extensions added by *HPX* (light gray) where:

- f function to invoke,
- p...: (optional) arguments,
- R: return type of f,
- action: action type defined by, `HPX_DEFINE_PLAIN_ACTION` or `HPX_DEFINE_COMPONENT_ACTION` encapsulating f,
- a: an instance of the type `action,
- id: the global address the action is applied to.

R f(p...)	Synchronous Execution (returns R)	Asynchronous Execution (returns <code>future&lt;R&gt;</code> )	Fire & Forget Execution (returns <code>void</code> )
Functions (direct invocation)	<code>f(p...)</code>  C++	<code>async(f, p...)</code>	<code>apply(f, p...)</code>
Functions (lazy invocation)	<code>bind(f, p...)(...)</code>	<code>async(bind(f, p...), ...)</code>  C++ Standard Library	<code>apply(bind(f, p...), ...)</code>
Actions (direct invocation)	<code>HPX_ACTION(f, action)</code> <code>a(id, p...)</code>	<code>HPX_ACTION(f, action)</code> <code>async(a, id, p...)</code>	<code>HPX_ACTION(f, action)</code> <code>apply(a, id, p...)</code>
Actions (lazy invocation)	<code>HPX_ACTION(f, action)</code> <code>bind(a, id, p...)(...)</code>	<code>HPX_ACTION(f, action)</code> <code>async(bind(a, id, p...), ...)</code>	<code>HPX_ACTION(f, action)</code> <code>apply(bind(a, id, p...), ...)</code>  HPX

Fig. 2.8: Overview of the main API exposed by *HPX*.

This figure shows that *HPX* allows the user to apply actions with a syntax similar to the C++ standard. In fact, all action types have an overloaded function operator allowing to synchronously apply the action. Further, *HPX* implements `hpx::async` which semantically works similar to the way `std::async` works for plain C++ function.

---

**Note:** The similarity of applying an action to conventional function invocations extends even further. *HPX* implements `hpx::bind` and `hpx::function` two facilities which are semantically equivalent to the `std::bind` and `std::function` types as defined by the C++11 Standard. While `hpx::async` extends beyond the conventional semantics by supporting actions and conventional C++ functions, the *HPX* facilities `hpx::bind` and `hpx::function` extend beyond the conventional standard facilities too. The *HPX* facilities not only support conventional functions, but can be used for actions as well.

---

Additionally, *HPX* exposes `hpx::apply` and `hpx::async_continue` both of which refine and extend the standard C++ facilities.

The different ways to invoke a function in *HPX* will be explained in more detail in the following sections.

## Applying an action asynchronously without any synchronization

This method ('fire and forget') will make sure the function associated with the action is scheduled to run on the target *locality*. Applying the action does not wait for the function to start running, instead it is a fully asynchronous operation. The following example shows how to apply the action as defined *in the previous section* on the local *locality* (the *locality* this code runs on):

```
some_global_action act;      // define an instance of some_global_action
hpx::apply(act, hpx::find_here(), 2.0);
```

(the function `hpx::find_here()` returns the id of the local *locality*, i.e. the *locality* this code executes on).

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```
some_component_action act;      // define an instance of some_component_action
hpx::apply(act, id, "42");
```

In this case any value returned from this action (e.g. in this case the integer 42 is ignored. Please look at *Action type definition* for the code defining the component action `some_component_action` used.

## Applying an action asynchronously with synchronization

This method will make sure the action is scheduled to run on the target *locality*. Applying the action itself does not wait for the function to start running or to complete, instead this is a fully asynchronous operation similar to using `hpx::apply` as described above. The difference is that this method will return an instance of a `hpx::future<>` encapsulating the result of the (possibly remote) execution. The future can be used to synchronize with the asynchronous operation. The following example shows how to apply the action from above on the local *locality*:

```
some_global_action act;      // define an instance of some_global_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), 2.0);
//
// ... other code can be executed here
//
f.get();      // this will possibly wait for the asynchronous operation to 'return'
```

(as before, the function `hpx::find_here()` returns the id of the local *locality* (the *locality* this code is executed on)).

---

**Note:** The use of a `hpx::future<void>` allows the current thread to synchronize with any remote operation not returning any value.

---

---

**Note:** Any `std::future<>` returned from `std::async()` is required to block in its destructor if the value has not been set for this future yet. This is not true for `hpx::future<>` which will never block in its destructor, even if the value has not been returned to the future yet. We believe that consistency in the behavior of futures is more important than standards conformance in this case.

---

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```
some_component_action act;      // define an instance of some_component_action
hpx::future<int> f = hpx::async(act, id, "42");
// ...
// ... other code can be executed here
//
cout << f.get();    // this will possibly wait for the asynchronous operation to 'return'
                    ↵42
```

---

**Note:** The invocation of `f.get()` will return the result immediately (without suspending the calling thread) if the result from the asynchronous operation has already been returned. Otherwise, the invocation of `f.get()` will suspend the execution of the calling thread until the asynchronous operation returns its result.

---

## Applying an action synchronously

This method will schedule the function wrapped in the specified action on the target `locality`. While the invocation appears to be synchronous (as we will see), the calling thread will be suspended while waiting for the function to return. Invoking a plain action (e.g. a global function) synchronously is straightforward:

```
some_global_action act;      // define an instance of some_global_action
act(hpx::find_here(), 2.0);
```

While this call looks just like a normal synchronous function invocation, the function wrapped by the action will be scheduled to run on a new thread and the calling thread will be suspended. After the new thread has executed the wrapped global function, the waiting thread will resume and return from the synchronous call.

Equivalently, any action wrapping a component member function can be invoked synchronously as follows:

```
some_component_action act;      // define an instance of some_component_action
int result = act(id, "42");
```

The action invocation will either schedule a new thread locally to execute the wrapped member function (as before, `id` is the global address of the component instance the member function should be invoked on), or it will send a parcel to the remote `locality` of the component causing a new thread to be scheduled there. The calling thread will be suspended until the function returns its result. This result will be returned from the synchronous action invocation.

It is very important to understand that this ‘synchronous’ invocation syntax in fact conceals an asynchronous function call. This is beneficial as the calling thread is suspended while waiting for the outcome of a potentially remote operation. The *HPX* thread scheduler will schedule other work in the meantime, allowing the application to make further progress while the remote result is computed. This helps overlapping computation with communication and hiding communication latencies.

---

**Note:** The syntax of applying an action is always the same, regardless whether the target `locality` is remote to the invocation `locality` or not. This is a very important feature of *HPX* as it frees the user from the task of keeping track what actions have to be applied locally and which actions are remote. If the target for applying an action is local, a new thread is automatically created and scheduled. Once this thread is scheduled and run, it will execute the function encapsulated by that action. If the target is remote, *HPX* will send a parcel to the remote `locality` which encapsulates the action and its parameters. Once the parcel is received on the remote `locality` *HPX* will create and schedule a new thread there. Once this thread runs on the remote `locality`, it will execute the function encapsulated by the action.

---

## Applying an action with a continuation but without any synchronization

This method is very similar to the method described in section [Applying an action asynchronously without any synchronization](#). The difference is that it allows the user to chain a sequence of asynchronous operations, while handing the (intermediate) results from one step to the next step in the chain. Where `hpx::apply` invokes a single function using ‘fire and forget’ semantics, `hpx::apply_continue` asynchronously triggers a chain of functions without the need for the execution flow ‘to come back’ to the invocation site. Each of the asynchronous functions can be executed on a different *locality*.

## Applying an action with a continuation and with synchronization

This method is very similar to the method described in section [Applying an action asynchronously with synchronization](#). In addition to what `hpx::async` can do, the functions `hpx::async_continue` takes an additional function argument. This function will be called as the continuation of the executed action. It is expected to perform additional operations and to make sure that a result is returned to the original invocation site. This method chains operations asynchronously by providing a continuation operation which is automatically executed once the first action has finished executing.

As an example we chain two actions, where the result of the first action is forwarded to the second action and the result of the second action is sent back to the original invocation site:

```
// first action
std::int32_t action1(std::int32_t i)
{
    return i+1;
}
HPX_PLAIN_ACTION(action1);      // defines action1_type

// second action
std::int32_t action2(std::int32_t i)
{
    return i*2;
}
HPX_PLAIN_ACTION(action2);      // defines action2_type

// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;      // define an instance of 'action1_type'
action2_type act2;      // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2),
        hpx::find_here(), 42);
hpx::cout << f.get() << "\n";  // will print: 86 ((42 + 1) * 2)
```

By default, the continuation is executed on the same *locality* as `hpx::async_continue` is invoked from. If you want to specify the *locality* where the continuation should be executed, the code above has to be written as:

```
// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;      // define an instance of 'action1_type'
action2_type act2;      // define an instance of 'action2_type'
hpx::future<int> f =
```

(continues on next page)

(continued from previous page)

```
hpx::async_continue(act1, hpx::make_continuation(act2, hpx::find_here()),
    hpx::find_here(), 42);
hpx::cout << f.get() << "\n"; // will print: 86 ((42 + 1) * 2)
```

Similarly, it is possible to chain more than 2 operations:

```
action1_type act1;      // define an instance of 'action1_type'
action2_type act2;      // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1,
        hpx::make_continuation(act2, hpx::make_continuation(act1)),
        hpx::find_here(), 42);
hpx::cout << f.get() << "\n"; // will print: 87 ((42 + 1) * 2 + 1)
```

The function `hpx::make_continuation` creates a special function object which exposes the following prototype:

```
struct continuation
{
    template <typename Result>
    void operator()(hpx::id_type id, Result&& result) const
    {
        ...
    }
};
```

where the parameters passed to the overloaded function `operator()` are:

- the `id` is the global id where the final result of the asynchronous chain of operations should be sent to (in most cases this is the id of the `hpx::future` returned from the initial call to `hpx::async_continue`. Any custom continuation function should make sure this `id` is forwarded to the last operation in the chain.
- the `result` is the result value of the current operation in the asynchronous execution chain. This value needs to be forwarded to the next operation.

---

**Note:** All of those operations are implemented by the predefined continuation function object which is returned from `hpx::make_continuation`. Any (custom) function object used as a continuation should conform to the same interface.

---

## Action error handling

Like in any other asynchronous invocation scheme it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In *HPX* all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation *locality*, where it is rethrown during synchronization with the calling thread.

---

**Important:** Exceptions thrown during asynchronous execution can be transferred back to the invoking thread only for the synchronous and the asynchronous case with synchronization. Like with any other unhandled exception, any exception thrown during the execution of an asynchronous action *without* synchronization will result in calling `hpx::terminate` causing the running application to exit immediately.

---

---

**Note:** Even if error handling internally relies on exceptions, most of the API functions exposed by HPX can be used without throwing an exception. Please see [Working with exceptions](#) for more information.

---

As an example, we will assume that the following remote function will be executed:

```
namespace app
{
    void some_function_with_error(int arg)
    {
        if (arg < 0) {
            HPX_THROW_EXCEPTION(bad_parameter, "some_function_with_error",
                "some really bad error happened");
        }
        // do something else...
    }

    // This will define the action type 'some_error_action' which represents
    // the function 'app::some_function_with_error'.
    HPX_PLAIN_ACTION(app::some_function_with_error, some_error_action);
}
```

The use of `HPX_THROW_EXCEPTION` to report the error encapsulates the creation of a `hpx::exception` which is initialized with the error code `hpx::bad_parameter`. Additionally it carries the passed strings, the information about the file name, line number, and call stack of the point the exception was thrown from.

We invoke this action using the synchronous syntax as described before:

```
// note: wrapped function will throw hpx::exception
some_error_action act;           // define an instance of some_error_action
try {
    act(hpx::find_here(), -3);   // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

If this action is invoked asynchronously with synchronization, the exception is propagated to the waiting thread as well and is re-thrown from the future's function `get()`:

```
// note: wrapped function will throw hpx::exception
some_error_action act;           // define an instance of some_error_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), -3);
try {
    f.get();                   // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

For more information about error handling please refer to the section [Working with exceptions](#). There we also explain how to handle error conditions without having to rely on exception.

## Writing components

A component in *HPX* is a C++ class which can be created remotely and for which its member functions can be invoked remotely as well. The following sections highlight how components can be defined, created, and used.

### Defining components

In order for a C++ class type to be managed remotely in *HPX*, the type must be derived from the `hpx::components::component_base` template type. We call such C++ class types ‘components’.

Note that the component type itself is passed as a template argument to the base class:

```
// header file some_component.hpp

#include <hpx/include/components.hpp>

namespace app
{
    // Define a new component type 'some_component'
    struct some_component
        : hpx::components::component_base<some_component>
    {
        // This member function is has to be invoked remotely
        int some_member_function(std::string const& s)
        {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function, some_member_
        ->action);
    };
}

// This will generate the necessary boiler-plate code for the action allowing
// it to be invoked remotely. This declaration macro has to be placed in the
// header file defining the component itself.
//
// Note: The second argument to the macro below has to be systemwide-unique
//       C++ identifiers
//
HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_component_
->some_action);
```

There is more boiler plate code which has to be placed into a source file in order for the component to be usable. Every component type is required to have macros placed into its source file, one for each component type and one macro for each of the actions defined by the component type.

For instance:

```
// source file some_component.cpp
```

(continues on next page)

(continued from previous page)

```
#include "some_component.hpp"

// The following code generates all necessary boiler plate to enable the
// remote creation of 'app::some_component' instances with 'hpx::new<>()'
//
using some_component = app::some_component;
using some_component_type = hpx::components::component<some_component>;

// Please note that the second argument to this macro must be a
// (system-wide) unique C++-style identifier (without any namespaces)
//
HPX_REGISTER_COMPONENT(some_component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation in the corresponding
// header file.
//
// Please note that the second argument to this macro must be a
// (system-wide) unique C++-style identifier (without any namespaces)
//
HPX_REGISTER_ACTION(app::some_component::some_member_action, some_component_some_action);
```

## Defining client side representation classes

Often it is very convenient to define a separate type for a component which can be used on the client side (from where the component is instantiated and used). This step might seem as unnecessary duplicating code, however it significantly increases the type safety of the code.

A possible implementation of such a client side representation for the component described in the previous section could look like:

```
#include <hpx/include/components.hpp>

namespace app
{
    // Define a client side representation type for the component type
    // 'some_component' defined in the previous section.
    //
    struct some_component_client
        : hpx::components::client_base<some_component_client, some_component>
    {
        using base_type = hpx::components::client_base<
            some_component_client, some_component>;

        some_component_client(hpx::future<hpx::id_type> && id)
            : base_type(std::move(id))
        {}

        hpx::future<int> some_member_function(std::string const& s)
        {
            some_component::some_member_action act;
```

(continues on next page)

(continued from previous page)

```

        return hpx::async(act, get_id(), s);
    }
};

}

```

A client side object stores the global id of the component instance it represents. This global id is accessible by calling the function `client_base<>::get_id()`. The special constructor which is provided in the example allows to create this client side object directly using the API function `hpx::new_`.

### Creating component instances

Instances of defined component types can be created in two different ways. If the component to create has a defined client side representation type, then this can be used, otherwise use the server type.

The following examples assume that `some_component_type` is the type of the server side implementation of the component to create. All additional arguments (see , ... notation below) are passed through to the corresponding constructor calls of those objects:

```

// create one instance on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = find_here();
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
hpx::future<std::vector<hpx::id_type>> f = hpx::new_<some_component_type[]>(
    hpx::binpacking(hpx::find_all_localities()), num, ...);

```

The examples below demonstrate the use of the same API functions for creating client side representation objects (instead of just plain ids). These examples assume that `client_type` is the type of the client side representation of the component type to create. As above, all additional arguments (see , ... notation below) are passed through to the corresponding constructor calls of the server side implementation objects corresponding to the `client_type`:

```

// create one instance on the given locality
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(hpx::colocated(here), ...);

```

(continues on next page)

(continued from previous page)

```
// create multiple instances on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<std::vector<client_type>> f =
    hpx::new_<client_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
hpx::future<std::vector<client_type>> f = hpx::new_<client_type[]>(
    hpx::binpacking(hpx::find_all_localities()), num, ...);
```

## Using component instances

### Segmented containers

In parallel programming, there is now a plethora of solutions aimed at implementing “partially contiguous” or segmented data structures, whether on shared memory systems or distributed memory systems. *HPX* implements such structures by drawing inspiration from Standard C++ containers.

### Using segmented containers

A segmented container is a template class that is described in the namespace `hpx`. All segmented containers are very similar semantically to their sequential counterpart (defined in namespace `std` but with an additional template parameter named `DistPolicy`). The distribution policy is an optional parameter that is passed last to the segmented container constructor (after the container size when no default value is given, after the default value if not). The distribution policy describes the manner in which a container is segmented and the placement of each segment among the available runtime localities.

However, only a part of the `std` container member functions were reimplemented:

- (constructor), (destructor), `operator=`
- `operator[]`
- `begin`, `cbegin`, `end`, `cend`
- `size`

An example of how to use the `partitioned_vector` container would be:

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

// By default, the number of segments is equal to the current number of
// localities
//
hpx::partitioned_vector<double> va(50);
hpx::partitioned_vector<double> vb(50, 0.0);
```

An example of how to use the `partitioned_vector` container with distribution policies would be:

```
#include <hpx/include/partitioned_vector.hpp>
#include <hpx/runtime_distributed/find_localities.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

std::size_t num_segments = 10;
std::vector<hpx::id_type> locs = hpx::find_all_localities()

auto layout =
    hpx::container_layout( num_segments, locs );

// The number of segments is 10 and those segments are spread across the
// localities collected in the variable locs in a Round-Robin manner
//
hpx::partitioned_vector<double> va(50, layout);
hpx::partitioned_vector<double> vb(50, 0.0, layout);
```

By definition, a segmented container must be accessible from any thread although its construction is synchronous only for the thread who has called its constructor. To overcome this problem, it is possible to assign a symbolic name to the segmented container:

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

hpx::future<void> fserver = hpx::async(
    [](){
        hpx::partitioned_vector<double> v(50);

        // Register the 'partitioned_vector' with the name "some_name"
        //
        v.register_as("some_name");

        /* Do some code */
    });

hpx::future<void> fclient =
    hpx::async(
        [](){
            // Naked 'partitioned_vector'
            //
            hpx::partitioned_vector<double> v;

            // Now the variable v points to the same 'partitioned_vector' that has
            // been registered with the name "some_name"
            //
        });

```

(continues on next page)

(continued from previous page)

```
v.connect_to("some_name");

/* Do some code */
});
```

## Segmented containers

HPX provides the following segmented containers:

Table 2.21: Sequence containers

Name	Description	In header	Class page at cppreference.com
hpx::partitioned_vector	Dynamic segmented contiguous array.	<hpx/include/partitioned_vector.hpp>	vector <sup>132</sup>

Table 2.22: Unordered associative containers

Name	Description	In header	Class page at cppreference.com
hpx::unordered_map	Segmented collection of key-value pairs, hashed by keys, keys are unique.	<hpx/include/unordered_map.hpp>	unordered_map <sup>133</sup>

## Segmented iterators and segmented iterator traits

The basic iterator used in the STL library is only suitable for one-dimensional structures. The iterators we use in HPX must adapt to the segmented format of our containers. Our iterators are then able to know when incrementing themselves if the next element of type T is in the same data segment or in another segment. In this second case, the iterator will automatically point to the beginning of the next segment.

---

**Note:** Note that the dereference operation operator \* does not directly return a reference of type T& but an intermediate object wrapping this reference. When this object is used as an l-value, a remote write operation is performed; When this object is used as an r-value, implicit conversion to T type will take care of performing remote read operation.

It is sometimes useful not only to iterate element by element, but also segment by segment, or simply get a local iterator in order to avoid additional construction costs at each dereferencing operations. To mitigate this need, the hpx::traits::segmented\_iterator\_traits are used.

With segmented\_iterator\_traits users can uniformly get the iterators which specifically iterates over segments (by providing a segmented iterator as a parameter), or get the local begin/end iterators of the nearest local segment (by providing a per-segment iterator as a parameter):

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
```

(continues on next page)

<sup>132</sup> <http://en.cppreference.com/w/cpp/container/vector>

<sup>133</sup> [http://en.cppreference.com/w/cpp/container/unordered\\_map](http://en.cppreference.com/w/cpp/container/unordered_map)

(continued from previous page)

```
//  
HPX_REGISTER_PARTITIONED_VECTOR(double);  
  
using iterator = hpx::partitioned_vector<T>::iterator;  
using traits = hpx::traits::segmented_iterator_traits<iterator>;  
  
hpx::partitioned_vector<T> v;  
std::size_t count = 0;  
  
auto seg_begin = traits::segment(v.begin());  
auto seg_end = traits::segment(v.end());  
  
// Iterate over segments  
for (auto seg_it = seg_begin; seg_it != seg_end; ++seg_it)  
{  
    auto loc_begin = traits::begin(seg_it);  
    auto loc_end = traits::end(seg_it);  
  
    // Iterate over elements inside segments  
    for (auto lit = loc_begin; lit != loc_end; ++lit, ++count)  
    {  
        *lit = count;  
    }  
}
```

Which is equivalent to:

```
hpx::partitioned_vector<T> v;  
std::size_t count = 0;  
  
auto begin = v.begin();  
auto end = v.end();  
  
for (auto it = begin; it != end; ++it, ++count)  
{  
    *it = count;  
}
```

## Using views

The use of multidimensional arrays is quite common in the numerical field whether to perform dense matrix operations or to process images. It exist many libraries which implement such object classes overloading their basic operators (e.g. `^`, `+`, `-`, `*`, `( )`, etc.). However, such operation becomes more delicate when the underlying data layout is segmented or when it is mandatory to use optimized linear algebra subroutines (i.e. BLAS subroutines).

Our solution is thus to relax the level of abstraction by allowing the user to work not directly on n-dimensionnal data, but on “n-dimensionnal collections of 1-D arrays”. The use of well-accepted techniques on contiguous data is thus preserved at the segment level, and the composability of the segments is made possible thanks to multidimensional array-inspired access mode.

## Preface: Why SPMD?

Although *HPX* refutes by design this programming model, the *locality* plays a dominant role when it comes to implement vectorized code. To maximize local computations and avoid unneeded data transfers, a parallel section (or Single Programming Multiple Data section) is required. Because the use of global variables is prohibited, this parallel section is created via the RAII idiom.

To define a parallel section, simply write an action taking a `spmd_block` variable as a first parameter:

```
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */)
{
    // Parallel section

    /* Do some code */
}
HPC_PLAIN_ACTION(bulk_function, bulk_action);
```

---

**Note:** In the following paragraphs, we will use the term “image” several times. An image is defined as a lightweight process whose entry point is a function provided by the user. It’s an “image of the function”.

---

The `spmd_block` class contains the following methods:

- [def Team information] `get_num_images`, `this_image`, `images_per_locality`
- [def Control statements] `sync_all`, `sync_images`

Here is a sample code summarizing the features offered by the `spmd_block` class:

```
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */)
{
    std::size_t num_images = block.get_num_images();
    std::size_t this_image = block.this_image();
    std::size_t images_per_locality = block.images_per_locality();

    /* Do some code */

    // Synchronize all images in the team
    block.sync_all();

    /* Do some code */

    // Synchronize image 0 and image 1
    block.sync_images(0,1);

    /* Do some code */

    std::vector<std::size_t> vec_images = {2,3,4};

    // Synchronize images 2, 3 and 4
    block.sync_images(vec_images);
```

(continues on next page)

(continued from previous page)

```

// Alternative call to synchronize images 2, 3 and 4
block.sync_images(vec_images.begin(), vec_images.end());

/* Do some code */

// Non-blocking version of sync_all()
hpx::future<void> event =
    block.sync_all(hpx::launch::async);

// Callback waiting for 'event' to be ready before being scheduled
hpx::future<void> cb =
    event.then(
        [] (hpx::future<void>)
    {

/* Do some code */

    });

// Finally wait for the execution tree to be finished
cb.get();
}

HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);

```

Then, in order to invoke the parallel section, call the function `define_spmd_block` specifying an arbitrary symbolic name and indicating the number of images per *locality* to create:

```

void bulk_function(hpx::lcos::spmd_block block, /* , arg0, arg1, ... */)
{
}

HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);

int main()
{
    /* std::size_t arg0, arg1, ...; */

    bulk_action act;
    std::size_t images_per_locality = 4;

    // Instantiate the parallel section
    hpx::lcos::define_spmd_block(
        "some_name", images_per_locality, std::move(act) /*, arg0, arg1, ... */);

    return 0;
}

```

---

**Note:** In principle, the user should never call the `spmd_block` constructor. The `define_spmd_block` function is responsible of instantiating `spmd_block` objects and broadcasting them to each created image.

---

## SPMD multidimensional views

Some classes are defined as “container views” when the purpose is to observe and/or modify the values of a container using another perspective than the one that characterizes the container. For example, the values of an `std::vector` object can be accessed via the expression `[i]`. Container views can be used, for example, when it is desired for those values to be “viewed” as a 2D matrix that would have been flattened in a `std::vector`. The values would be possibly accessible via the expression `vv(i, j)` which would call internally the expression `v[k]`.

By default, the `partitioned_vector` class integrates 1-D views of its segments:

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<double>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<double> v;

// Create a 1-D view of the vector of segments
auto vv = traits::segment(v.begin());

// Access segment i
std::vector<double> v = vv[i];
```

Our views are called “multidimensional” in the sense that they generalize to N dimensions the purpose of `segmented_iterator_traits::segment()` in the 1-D case. Note that in a parallel section, the 2-D expression `a(i, j) = b(i, j)` is quite confusing because without convention, each of the images invoked will race to execute the statement. For this reason, our views are not only multidimensional but also “spmd-aware”.

---

**Note:** SPMD-awareness: The convention is simple. If an assignment statement contains a view subscript as an l-value, it is only and only the image holding the r-value who is evaluating the statement. (In MPI sense, it is called a Put operation).

---

## Subscript-based operations

Here are some examples of using subscripts in the 2-D view case:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using Vec = hpx::partitioned_vector<double>;
using View_2D = hpx::partitioned_vector_view<double, 2>;
```

(continues on next page)

(continued from previous page)

```

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t height, width;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {height, width});

    // The l-value is a view subscript, the image that owns vv(1,0)
    // evaluates the assignment.
    vv(0,1) = vv(1,0);

    // The l-value is a view subscript, the image that owns the r-value
    // (result of expression 'std::vector<double>(4,1.0)') evaluates the
    // assignment : oops! race between all participating images.
    vv(2,3) = std::vector<double>(4,1.0);
}

```

## Iterator-based operations

Here are some examples of using iterators in the 3-D view case:

```

#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(int);

using Vec = hpx::partitioned_vector<int>;
using View_3D = hpx::partitioned_vector_view<int,3>;

/* Do some code */

Vec v1, v2;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t size_x, size_y, size_z;

    // Instantiate the views
    View_3D vv1(block, v1.begin(), v1.end(), {size_x, size_y, size_z});
    View_3D vv2(block, v2.begin(), v2.end(), {size_x, size_y, size_z});

    // Save previous segments covered by vv1 into segments covered by vv2
    auto vv2_it = vv2.begin();

```

(continues on next page)

(continued from previous page)

```

auto vv1_it = vv1.cbegin();

for(; vv2_it != vv2.end(); vv2_it++, vv1_it++)
{
    // It's a Put operation
    *vv2_it = *vv1_it;
}

// Ensure that all images have performed their Put operations
block.sync_all();

// Ensure that only one image is putting updated data into the different
// segments covered by vv1
if(block.this_image() == 0)
{
    int idx = 0;

    // Update all the segments covered by vv1
    for(auto i = vv1.begin(); i != vv1.end(); i++)
    {
        // It's a Put operation
        *i = std::vector<float>(elt_size, idx++);
    }
}
}

```

Here is an example that shows how to iterate only over segments owned by the current image:

```

#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/components/containers/partitioned_vector/partitioned_vector_local_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_1D = hpx::partitioned_vector_view<float,1>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t num_segments;

    // Instantiate the view
    View_1D vv(block, v.begin(), v.end(), {num_segments});

    // Instantiate the local view from the view

```

(continues on next page)

(continued from previous page)

```

auto local_vv = hpx::local_view(vv);

for ( auto i = local_vv.begin(); i != local_vv.end(); i++ )
{
    std::vector<float> & segment = *i;

    /* Do some code */
}

}

```

## Instantiating sub-views

It is possible to construct views from other views: we call it sub-views. The constraint nevertheless for the subviews is to retain the dimension and the value type of the input view. Here is an example showing how to create a sub-view:

```

#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_2D = hpx::partitioned_vector_view<float,2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t N = 20;
    std::size_t tilesize = 5;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {N,N});

    // Instantiate the subview
    View_2D svv(
        block,&vv(tilesize,0),&vv(2*tilesize-1,tilesize-1),{tilesize,tilesize},{N,N});

    if(block.this_image() == 0)
    {
        // Equivalent to 'vv(tilesize,0) = 2.0f'
        svv(0,0) = 2.0f;

        // Equivalent to 'vv(2*tilesize-1,tilesize-1) = 3.0f'
        svv(tilesize-1,tilesize-1) = 3.0f;
    }
}

```

(continues on next page)

(continued from previous page)

}

**Note:** The last parameter of the subview constructor is the size of the original view. If one would like to create a subview of the subview and so on, this parameter should stay unchanged. {N,N} for the above example).

## C++ co-arrays

Fortran has extended its scalar element indexing approach to reference each segment of a distributed array. In this extension, a segment is attributed a ?co-index? and lives in a specific *locality*. A co-index provides the application with enough information to retrieve the corresponding data reference. In C++, containers present themselves as a ?smarter? alternative of Fortran arrays but there are still no corresponding standardized features similar to the Fortran co-indexing approach. We present here an implementation of such features in *HPX*.

### Preface: co-array, a segmented container tied to a SPMD multidimensional views

As mentioned before, a co-array is a distributed array whose segments are accessible through an array-inspired access mode. We have previously seen that it is possible to reproduce such access mode using the concept of views. Nevertheless, the user must pre-create a segmented container to instantiate this view. We illustrate below how a single constructor call can perform those two operations:

```
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'
//
HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height=32, width=4, segment_size=10;

    hpx::coarray<double,3> a(block, "a", {height,width,_}, segment_size);

    /* Do some code */
}
```

Unlike segmented containers, a co-array object can only be instantiated within a parallel section. Here is the description of the parameters to provide to the coarray constructor:

Table 2.23: Parameters of coarray constructor

Parameter	Description
<code>block</code>	Reference to a <code>spmd_block</code> object
<code>"a"</code>	Symbolic name of type <code>std::string</code>
<code>{height, width, _}</code>	Dimensions of the coarray object
<code>segment_size</code>	Size of a co-indexed element (i.e. size of the object referenced by the expression <code>a(i, j, k)</code> )

Note that the “last dimension size” cannot be set by the user. It only accepts the `constexpr` variable `hpx::container::placeholders::_`. This size, which is considered private, is equal to the number of current images (value returned by `block.get_num_images()`).

---

**Note:** An important constraint to remember about coarray objects is that all segments sharing the same “last dimension index” are located in the same image.

---

## Using co-arrays

The member functions owned by the coarray objects are exactly the same as those of spmd multidimensional views. These are:

- \* Subscript-based operations
- \* Iterator-based operations

However, one additional functionality is provided. Knowing that the element `a(i, j, k)` is in the memory of the `k`th image, the use of local subscripts is possible.

---

**Note:** For spmd multidimensional views, subscripts are only global as it still involves potential remote data transfers.

---

Here is an example of using local subscripts:

```
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'
// 
HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height=32, width=4, segment_size=10;

    hpx::coarray<double,3> a(block, "a", {height,width,_}, segment_size);

    double idx = block.this_image()*height*width;

    for (std::size_t j = 0; j<width; j++)

```

(continues on next page)

(continued from previous page)

```

for (std::size_t i = 0; i<height; i++)
{
    // Local write operation performed via the use of local subscript
    a(i,j,...) = std::vector<double>(elt_size, idx);
    idx++;
}

block.sync_all();
}

```

**Note:** When the “last dimension index” of a subscript is equal to `hpx::container::placeholders::_`, local subscript (and not global subscript) is used. It is equivalent to a global subscript used with a “last dimension index” equal to the value returned by `block.this_image()`.

### 2.3.10 Running on batch systems

This section walks you through launching *HPX* applications on various batch systems.

#### How to use *HPX* applications with PBS

Most *HPX* applications are executed on parallel computers. These platforms typically provide integrated job management services that facilitate the allocation of computing resources for each parallel program. *HPX* includes support for one of the most common job management systems, the Portable Batch System (PBS).

All PBS jobs require a script to specify the resource requirements and other parameters associated with a parallel job. The PBS script is basically a shell script with PBS directives placed within commented sections at the beginning of the file. The remaining (not commented-out) portions of the file executes just like any other regular shell script. While the description of all available PBS options is outside the scope of this tutorial (the interested reader may refer to in-depth documentation<sup>134</sup> for more information), below is a minimal example to illustrate the approach. The following test application will use the multithreaded `hello_world_distributed` program, explained in the section *Remote execution with actions*.

```

#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

**Caution:** If the first application specific argument (inside `$APP_OPTIONS`) is a non-option (i.e., does not start with a `-` or a `--`), then the argument has to be placed before the option `--hpx:nodes`, which, in this case, should be the last option on the command line.

Alternatively, use the option `--hpx:endnodes` to explicitly mark the end of the list of node names:

```
$ pbsdsh -u $APP_PATH --hpx:nodes`cat $PBS_NODEFILE` --hpx:endnodes $APP_OPTIONS
```

<sup>134</sup> <http://www.clusterresources.com/torquedocs21/>

The `#PBS -l nodes=2:ppn=4` directive will cause two compute nodes to be allocated for the application, as specified in the option `nodes`. Each of the nodes will dedicate four cores to the program, as per the option `ppn`, short for “processors per node” (PBS does not distinguish between processors and cores). Note that requesting more cores per node than physically available is pointless and may prevent PBS from accepting the script.

On newer PBS versions the PBS command syntax might be different. For instance, the PBS script above would look like:

```
#!/bin/bash
#
#PBS -l select=2:ncpus=
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=
pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:node=cat $PBS_NODEFILE`
```

`APP_PATH` and `APP_OPTIONS` are shell variables that respectively specify the correct path to the executable (`hello_world_distributed` in this case) and the command line options. Since the `hello_world_distributed` application doesn’t need any command line options, `APP_OPTIONS` has been left empty. Unlike in other execution environments, there is no need to use the `--hpx:threads` option to indicate the required number of OS threads per node; the `HPX` library will derive this parameter automatically from PBS.

Finally, `pbsdsh` is a PBS command that starts tasks to the resources allocated to the current job. It is recommended to leave this line as shown and modify only the PBS options and shell variables as needed for a specific application.

---

**Important:** A script invoked by `pbsdsh` starts in a very basic environment: the user’s `$HOME` directory is defined and is the current directory, the `LANG` variable is set to C and the `PATH` is set to the basic `/usr/local/bin:/usr/bin:/bin` as defined in a system-wide file `pbs_environment`. Nothing that would normally be set up by a system shell profile or user shell profile is defined, unlike the environment for the main job script.

---

Another choice is for the `pbsdsh` command in your main job script to invoke your program via a shell, like `sh` or `bash`, so that it gives an initialized environment for each instance. Users can create a small script `runme.sh`, which is used to invoke the program:

```
#!/bin/bash
# Small script which invokes the program based on what was passed on its
# command line.
#
# This script is executed by the bash shell which will initialize all
# environment variables as usual.
$@
```

Now, the script is invoked using the `pbsdsh` tool:

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=
```

(continues on next page)

(continued from previous page)

```
pbsdsh -u runme.sh $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

All that remains now is submitting the job to the queuing system. Assuming that the contents of the PBS script were saved in the file `pbs_hello_world.sh` in the current directory, this is accomplished by typing:

```
$ qsub ./pbs_hello_world_pbs.sh
```

If the job is accepted, `qsub` will print out the assigned job ID, which may look like:

```
$ 42.supercomputer.some.university.edu
```

To check the status of your job, issue the following command:

```
$ qstat 42.supercomputer.some.university.edu
```

and look for a single-letter job status symbol. The common cases include:

- *Q* - signifies that the job is queued and awaiting its turn to be executed.
- *R* - indicates that the job is currently running.
- *C* - means that the job has completed.

The example `qstat` output below shows a job waiting for execution resources to become available:

Job id	Name	User	Time Use S Queue
42.supercomputer	...ello_world.sh	joe_user	0 Q batch

After the job completes, PBS will place two files, `pbs_hello_world.sh.o42` and `pbs_hello_world.sh.e42`, in the directory where the job was submitted. The first contains the standard output and the second contains the standard error from all the nodes on which the application executed. In our example, the error output file should be empty and the standard output file should contain something similar to:

```
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 1
hello world from OS-thread 2 on locality 1
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 1
```

Congratulations! You have just run your first distributed *HPX* application!

## How to use HPX applications with SLURM

Just like PBS (described in section [How to use HPX applications with PBS](#)), SLURM is a job management system which is widely used on large supercomputing systems. Any *HPX* application can easily be run using SLURM. This section describes how this can be done.

The easiest way to run an *HPX* application using SLURM is to utilize the command line tool `srun`, which interacts with the SLURM batch scheduling system:

```
$ srun -p <partition> -N <number-of-nodes> hpx-application <application-arguments>
```

Here, `<partition>` is one of the node partitions existing on the target machine (consult the machine's documentation to get a list of existing partitions) and `<number-of-nodes>` is the number of compute nodes that should be used. By default, the *HPX* application is started with one *locality* per node and uses all available cores on a node. You can change the number of localities started per node (for example, to account for NUMA effects) by specifying the `-n` option of `srun`. The number of cores per *locality* can be set by `-c`. The `<application-arguments>` are any application specific arguments that need to be passed on to the application.

---

**Note:** There is no need to use any of the *HPX* command line options related to the number of localities, number of threads, or related to networking ports. All of this information is automatically extracted from the SLURM environment by the *HPX* startup code.

---

**Important:** The `srun` documentation explicitly states: "If `-c` is specified without `-n`, as many tasks will be allocated per node as possible while satisfying the `-c` restriction. For instance on a cluster with 8 CPUs per node, a job request for 4 nodes and 3 CPUs per task may be allocated 3 or 6 CPUs per node (1 or 2 tasks per node) depending upon resource consumption by other jobs." For this reason, it's recommended to always specify `-n <number-of-instances>`, even if `<number-of-instances>` is equal to one (1).

---

## Interactive shells

To get an interactive development shell on one of the nodes, users can issue the following command:

```
$ srun -p <node-type> -N <number-of-nodes> --pty /bin/bash -l
```

After the shell has been opened, users can run their *HPX* application. By default, it uses all available cores. Note that if you requested one node, you don't need to do `srun` again. However, if you requested more than one node, and want to run your distributed application, you can use `srun` again to start up the distributed *HPX* application. It will use the resources that have been requested for the interactive shell.

## Scheduling batch jobs

The above mentioned method of running *HPX* applications is fine for development purposes. The disadvantage that comes with `srun` is that it only returns once the application is finished. This might not be appropriate for longer-running applications (for example, benchmarks or larger scale simulations). In order to cope with that limitation, users can use the `sbatch` command.

The `sbatch` command expects a script that it can run once the requested resources are available. In order to request resources, users need to add `#SBATCH` comments in their script or provide the necessary parameters to `sbatch` directly. The parameters are the same as with `run`. The commands you need to execute are the same you would need to start your application as if you were in an interactive shell.

### 2.3.11 Debugging HPX applications

#### Using a debugger with HPX applications

Using a debugger such as `gdb` with *HPX* applications is no problem. However, there are some things to keep in mind to make the experience somewhat more productive.

Call stacks in *HPX* can often be quite unwieldy as the library is heavily templated and the call stacks can be very deep. For this reason it is sometimes a good idea compile *HPX* in `RelWithDebInfo` mode, which applies some optimizations but keeps debugging symbols. This can often compress call stacks significantly. On the other hand, stepping through the code can also be more difficult because of statements being reordered and variables being optimized away. Also, note that because *HPX* implements user-space threads and context switching, call stacks may not always be complete in a debugger.

*HPX* launches not only worker threads but also a few helper threads. The first thread is the main thread, which typically does no work in an *HPX* application, except at startup and shutdown. If using the default settings, *HPX* will spawn six additional threads (used for service thread pools). The first worker thread is usually the eighth thread, and most user codes will be run on these worker threads. The last thread is a helper thread used for *HPX* shutdown.

Finally, since *HPX* is a multi-threaded runtime, the following `gdb` options can be helpful:

```
set pagination off
set non-stop on
```

Non-stop mode allows users to have a single thread stop on a breakpoint without stopping all other threads as well.

#### Using sanitizers with HPX applications

**Warning:** Not all parts of *HPX* are sanitizer clean. This means that users may end up with false positives from *HPX* itself when using sanitizers for their applications.

To use sanitizers with *HPX*, turn on `HPX_WITH_SANITIZERS` and turn off `HPX_WITH_STACKOVERFLOW_DETECTION` during CMake configuration. It's recommended to also build Boost with the same sanitizers that will be used for *HPX*. The appropriate sanitizers can then be enabled using CMake by appending `-fsanitize=address -fno-omit-frame-pointer` to `CMAKE_CXX_FLAGS` and `-fsanitize=address` to `CMAKE_EXE_LINKER_FLAGS`. Replace `address` with the sanitizer that you want to use.

#### Debugging applications using core files

For *HPX* to generate useful core files, *HPX* has to be compiled without signal and exception handlers `HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`. If this option is not specified, the signal handlers change the application state. For example, after a segmentation fault the stack trace will show the signal handler. Similarly, unhandled exceptions are also caught by these handlers and the stack trace will not point to the location where the unhandled exception was thrown.

In general, core files are a helpful tool to inspect the state of the application at the moment of the crash (post-mortem debugging), without the need of attaching a debugger beforehand. This approach to debugging is especially useful if the error cannot be reliably reproduced, as only a single crashed application run is required to gain potentially helpful information like a stacktrace.

To debug with core files, the operating system first has to be told to actually write them. On most Unix systems this can be done by calling:

```
$ ulimit -c unlimited
```

in the shell. Now the debugger can be started up with:

```
$ gdb <application> <core file name>
```

The debugger should now display the last state of the application. The default file name for core files is `core`.

### 2.3.12 Optimizing HPX applications

#### Performance counters

Performance counters in *HPX* are used to provide information as to how well the runtime system or an application is performing. The counter data can help determine system bottlenecks, and fine-tune system and application performance. The *HPX* runtime system, its networking, and other layers provide counter data that an application can consume to provide users with information about how well the application is performing.

Applications can also use counter data to determine how much system resources to consume. For example, an application that transfers data over the network could consume counter data from a network switch to determine how much data to transfer without competing for network bandwidth with other network traffic. The application could use the counter data to adjust its transfer rate as the bandwidth usage from other network traffic increases or decreases.

Performance counters are *HPX* parallel processes that expose a predefined interface. *HPX* exposes special API functions that allow one to create, manage, and read the counter data, and release instances of performance counters. Performance Counter instances are accessed by name, and these names have a predefined structure which is described in the section [Performance counter names](#). The advantage of this is that any Performance Counter can be accessed remotely (from a different *locality*) or locally (from the same *locality*). Moreover, since all counters expose their data using the same API, any code consuming counter data can be utilized to access arbitrary system information with minimal effort.

Counter data may be accessed in real time. More information about how to consume counter data can be found in the section [Consuming performance counter data](#).

All *HPX* applications provide command line options related to performance counters, such as the ability to list available counter types, or periodically query specific counters to be printed to the screen or save them in a file. For more information, please refer to the section [HPX Command Line Options](#).

#### Performance counter names

All Performance Counter instances have a name uniquely identifying each instance. This name can be used to access the counter, retrieve all related meta data, and to query the counter data (as described in the section [Consuming performance counter data](#)). Counter names are strings with a predefined structure. The general form of a countername is:

```
/objectname{full_instancename}/countername@parameters
```

where `full_instancename` could be either another (full) counter name or a string formatted as:

```
parentinstancename#parentindex/instancename#instanceindex
```

Each separate part of a countername (e.g., `objectname`, `countername` `parentinstancename`, `instancename`, and `parameters`) should start with a letter ('a'... 'z', 'A'... 'Z') or an underscore character ('\_'), optionally followed by letters, digits ('0'... '9'), hyphen ('-'), or underscore characters. Whitespace is not allowed inside a counter name. The characters '/', '{', '}', '#' and '@' have a special meaning and are used to delimit the different parts of the counter name.

The parts `parentinstanceindex` and `instanceindex` are integers. If an index is not specified, *HPX* will assume a default of -1.

## Two counter name examples

This section gives examples of both simple counter names and aggregate counter names. For more information on simple and aggregate counter names, please see [Performance counter instances](#).

An example of a well-formed (and meaningful) simple counter name would be:

```
/threads{locality#0/total}/count/cumulative
```

This counter returns the current cumulative number of executed (retired) *HPX* threads for the `locality` 0. The counter type of this counter is `/threads/count/cumulative` and the full instance name is `locality#0/total`. This counter type does not require an `instanceindex` or `parameters` to be specified.

In this case, the `parentindex` (the '0') designates the `locality` for which the counter instance is created. The counter will return the number of *HPX* threads retired on that particular `locality`.

Another example for a well formed (aggregate) counter name is:

```
/statistics{/threads{locality#0/total}/count/cumulative}/average@500
```

This counter takes the simple counter from the first example, samples its values every 500 milliseconds, and returns the average of the value samples whenever it is queried. The counter type of this counter is `/statistics/average` and the instance name is the full name of the counter for which the values have to be averaged. In this case, the `parameters` (the '500') specify the sampling interval for the averaging to take place (in milliseconds).

## Performance counter types

Every performance counter belongs to a specific performance counter type which classifies the counters into groups of common semantics. The type of a counter is identified by the `objectname` and the `countername` parts of the name.

```
/objectname/countername
```

When an application starts *HPX* will register all available counter types on each of the localities. These counter types are held in a special performance counter registration database, which can be used to retrieve the meta data related to a counter type and to create counter instances based on a given counter instance name.

## Performance counter instances

The `full_instanceName` distinguishes different counter instances of the same counter type. The formatting of the `full_instanceName` depends on the counter type. There are two types of counters: simple counters, which usually generate the counter values based on direct measurements, and aggregate counters, which take another counter and transform its values before generating their own counter values. An example for a simple counter is given [above](#): counting retired *HPX* threads. An aggregate counter is shown as an example [above](#) as well: calculating the average of the underlying counter values sampled at constant time intervals.

While simple counters use instance names formatted as `parentinstancename#parentindex/instancename#instanceindex`, most aggregate counters have the full counter name of the embedded counter as their instance name.

Not all simple counter types require specifying all four elements of a full counter instance name; some of the parts (`parentinstancename`, `parentindex`, `instancename`, and `instanceindex`) are optional for specific counters.

Please refer to the documentation of a particular counter for more information about the formatting requirements for the name of this counter (see [Existing HPX performance counters](#)).

The parameters are used to pass additional information to a counter at creation time. They are optional, and they fully depend on the concrete counter. Even if a specific counter type allows additional parameters to be given, those usually are not required as sensible defaults will be chosen. Please refer to the documentation of a particular counter for more information about what parameters are supported, how to specify them, and what default values are assumed (see also [Existing HPX performance counters](#)).

Every *locality* of an application exposes its own set of performance counter types and performance counter instances. The set of exposed counters is determined dynamically at application start based on the execution environment of the application. For instance, this set is influenced by the current hardware environment for the *locality* (such as whether the *locality* has access to accelerators), and the software environment of the application (such as the number of OS threads used to execute *HPX* threads).

## Using wildcards in performance counter names

It is possible to use wildcard characters when specifying performance counter names. Performance counter names can contain two types of wildcard characters:

- Wildcard characters in the performance counter type
- Wildcard characters in the performance counter instance name

A wildcard character has a meaning which is very close to usual file name wildcard matching rules implemented by common shells (like bash).

Table 2.24: Wildcard characters in the performance counter type

Wild-card	Description
*	This wildcard character matches any number (zero or more) of arbitrary characters.
?	This wildcard character matches any single arbitrary character.
[...]	This wildcard character matches any single character from the list of specified within the square brackets.

Table 2.25: Wildcard characters in the performance counter instance name

Wild-card	Description
*	This wildcard character matches any <i>locality</i> or any thread, depending on whether it is used for <i>locality#*</i> or <i>worker-thread#*</i> . No other wildcards are allowed in counter instance names.

## Consuming performance counter data

You can consume performance data using either the command line interface, the *HPX* application or the *HPX* API. The command line interface is easier to use, but it is less flexible and does not allow one to adjust the behaviour of your application at runtime. The command line interface provides a convenience abstraction but simplified abstraction for querying and logging performance counter data for a set of performance counters.

## Consuming performance counter data from the command line

HPX provides a set of predefined command line options for every application that uses `hpx::init` for its initialization. While there are many more command line options available (see [HPX Command Line Options](#)), the set of options related to performance counters allows one to list existing counters, and query existing counters once at application termination or repeatedly after a constant time interval.

The following table summarizes the available command line options:

Table 2.26: HPX Command Line Options Related to Performance Counters

Command line option	Description
<code>--hpx:print</code>	Prints the specified performance counter either repeatedly and/or at the times specified by <code>--hpx:print-counter-at</code> (see also option <code>--hpx:print-counter-interval</code> ).
<code>--hpx:print</code>	Prints the specified performance counter either repeatedly and/or at the times specified by <code>--hpx:print-counter-at</code> . Reset the counter after the value is queried (see also option <code>--hpx:print-counter-interval</code> ).
<code>--hpx:print</code>	Prints the performance counter(s) specified with <code>--hpx:print-counter</code> repeatedly after the time interval (specified in milliseconds) (default: 0 which means print once at shutdown).
<code>--hpx:print</code>	Prints the performance counter(s) specified with <code>--hpx:print-counter</code> to the given file (default: console).
<code>--hpx:list</code>	Lists the names of all registered performance counters.
<code>--hpx:list</code>	Lists the description of all registered performance counters.
<code>--hpx:print</code>	Prints the performance counter(s) specified with <code>--hpx:print-counter</code> . Possible formats in CSV format with header or without any header (see option <code>--hpx:no-csv-header</code> ), possible values: <code>csv</code> (prints counter values in CSV format with full names as header) <code>csv-short</code> (prints counter values in CSV format with shortnames provided with <code>--hpx:print-counter</code> as <code>--hpx:print-counter shortname,full-countername</code> ).
<code>--hpx:no-csv-header</code>	Prints the performance counter(s) specified with <code>--hpx:print-counter</code> and <code>csv</code> or <code>csv-short</code> format specified with <code>--hpx:print-counter-format</code> without header.
<code>--hpx:print</code>	Prints the <code>at</code> performance counter(s) specified with <code>--hpx:print-counter</code> (or arg <code>--hpx:print-counter-reset</code> ) at the given point in time. Possible argument values: <code>startup</code> , <code>shutdown</code> (default), <code>noshutdown</code> .
<code>--hpx:reset</code>	Resets the performance counter(s) specified with <code>--hpx:print-counter</code> after they have been evaluated.
<code>--hpx:print</code>	Appends the <code>type</code> description to generated output.
<code>--hpx:print</code>	Prints locally its own local counters.

While the options `--hpx:list-counters` and `--hpx:list-counter-infos` give a short list of all available counters, the full documentation for those can be found in the section [Existing HPX performance counters](#).

## A simple example

All of the commandline options mentioned above can be tested using the `hello_world_distributed` example.

Listing all available counters `hello_world_distributed --hpx:list-counters` yields:

```
List of available counter instances (replace * below with the appropriate sequence number)
-----
/agas/count/allocate /agas/count/bind /agas/count/bind_gid
/agas/count/bind_name ... /threads{locality#*/allocator#*}/count/objects
/threads{locality#*/total}/count/stack-recycles
/threads{locality#*/total}/idle-rate
/threads{locality#*/worker-thread#*}/idle-rate
```

Providing more information about all available counters, `hello_world_distributed --hpx:list-counter-infos` yields:

```
Information about available counter instances (replace * below with the appropriate sequence number)
-----
fullname: /agas/count/allocate helptext: returns the number of invocations of the AGAS service 'allocate' type: counter_type::raw version: 1.0.0
-----
fullname: /agas/count/bind helptext: returns the number of invocations of the AGAS service 'bind' type: counter_type::raw version: 1.0.0
-----
fullname: /agas/count/bind_gid helptext: returns the number of invocations of the AGAS service 'bind_gid' type: counter_type::raw version: 1.0.0
-----
...
```

This command will not only list the counter names but also a short description of the data exposed by this counter.

---

**Note:** The list of available counters may differ depending on the concrete execution environment (hardware or software) of your application.

---

Requesting the counter data for one or more performance counters can be achieved by invoking `hello_world_distributed` with a list of counter names:

```
$ hello_world_distributed \
  --hpx:print-counter=/threads{locality#0/total}/count/cumulative \
  --hpx:print-counter=/agas{locality#0/total}/count/bind
```

which yields for instance:

```
hello world from OS-thread 0 on locality 0
/threads{locality#0/total}/count/cumulative,1,0.212527,[s],33
/agas{locality#0/total}/count/bind,1,0.212790,[s],11
```

The first line is the normal output generated by `hello_world_distributed` and has no relation to the counter data listed. The last two lines contain the counter data as gathered at application shutdown. These lines have six fields, the counter name, the sequence number of the counter invocation, the time stamp at which this information has been sampled, the unit of measure for the time stamp, the actual counter value and an optional unit of measure for the counter value.

---

**Note:** The command line option `--hpx:print-counter-types` will append a seventh field to the generated output. This field will hold an abbreviated counter type.

---

The actual counter value can be represented by a single number (for counters returning singular values) or a list of numbers separated by ':' (for counters returning an array of values, like for instance a histogram).

---

**Note:** The name of the performance counter will be enclosed in double quotes "" if it contains one or more commas ','.

---

Requesting to query the counter data once after a constant time interval with this command line:

```
$ hello_world_distributed \
  --hpx:print-counter=/threads{locality#0/total}/count/cumulative \
  --hpx:print-counter=/agas{locality#0/total}/count/bind \
  --hpx:print-counter-interval=20
```

yields for instance (leaving off the actual console output of the `hello_world_distributed` example for brevity):

```
threads{locality#0/total}/count/cumulative,1,0.002409,[s],22
agas{locality#0/total}/count/bind,1,0.002542,[s],9
threads{locality#0/total}/count/cumulative,2,0.023002,[s],41
agas{locality#0/total}/count/bind,2,0.023557,[s],10
threads{locality#0/total}/count/cumulative,3,0.037514,[s],46
agas{locality#0/total}/count/bind,3,0.038679,[s],10
```

The command `--hpx:print-counter-destination=<file>` will redirect all counter data gathered to the specified file name, which avoids cluttering the console output of your application.

The command line option `--hpx:print-counter` supports using a limited set of wildcards for a (very limited) set of use cases. In particular, all occurrences of `#*` as in `locality#*` and in `worker-thread#*` will be automatically expanded to the proper set of performance counter names representing the actual environment for the executed program. For instance, if your program is utilizing four worker threads for the execution of *HPX* threads (see command line option `--hpx:threads`) the following command line

```
$ hello_world_distributed \
  --hpx:threads=4 \
  --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative
```

will print the value of the performance counters monitoring each of the worker threads:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.0025214,[s],27
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.0025453,[s],33
```

(continues on next page)

(continued from previous page)

```
/threads{locality#0/worker-thread#2}/count/cumulative,1,0.0025683,[s],29
/threads{locality#0/worker-thread#3}/count/cumulative,1,0.0025904,[s],33
```

The command `--hpx:print-counter-format` takes values `csv` and `csv-short` to generate CSV formatted counter values with a header.

With format as csv:

```
$ hello_world_distributed \
--hpx:threads=2 \
--hpx:print-counter-format csv \
--hpx:print-counter /threads{locality#*/total}/count/cumulative \
--hpx:print-counter /threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the full countername as a header:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
/threads{locality#*/total}/count/cumulative,/threads{locality#*/total}/count/cumulative-
→phases
39,93
```

With format csv-short:

```
$ hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the short countername as a header:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
cumulative,phases
39,93
```

With format csv and csv-short when used with `--hpx:print-counter-interval`:

```
$ hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
--hpx:print-counter-interval 5
```

will print the header only once repeating the performance counter value(s) repeatedly:

```
cum,phases
25,42
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
44,95
```

The command `--hpx:no-csv-header` can be used with `--hpx:print-counter-format` to print performance counter values in CSV format without any header:

```
$ hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#/total}/count/cumulative-phases \
--hpx:no-csv-header
```

will print:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
37,91
```

## Consuming performance counter data using the HPX API

HPX provides an API that allows users to discover performance counters and to retrieve the current value of any existing performance counter from any application.

### Discover existing performance counters

#### Retrieve the current value of any performance counter

Performance counters are specialized HPX components. In order to retrieve a counter value, the performance counter needs to be instantiated. HPX exposes a client component object for this purpose:

```
hpx::performance_counters::performance_counter counter(std::string const& name);
```

Instantiating an instance of this type will create the performance counter identified by the given name. Only the first invocation for any given counter name will create a new instance of that counter. All following invocations for a given counter name will reference the initially created instance. This ensures that at any point in time there is never more than one active instance of any of the existing performance counters.

In order to access the counter value (or to invoke any of the other functionality related to a performance counter, like `start`, `stop` or `reset`) member functions of the created client component instance should be called:

```
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count(
    "/threads{locality#0/total}/count/cumulative");
hpx::cout << count.get_value<int>().get() << std::endl;
```

For more information about the client component type, see `hpx::performance_counters::performance_counter`

---

**Note:** In the above example `count.get_value()` returns a future. In order to print the result we must append `.get()` to retrieve the value. You could write the above example like this for more clarity:

```
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count(
    "/threads{locality#0/total}/count/cumulative");
```

(continues on next page)

(continued from previous page)

```
hpx::future<int> result = count.get_value<int>();
hpx::cout << result.get() << std::endl;
```

## Providing performance counter data

HPX offers several ways by which you may provide your own data as a performance counter. This has the benefit of exposing additional, possibly application-specific information using the existing Performance Counter framework, unifying the process of gathering data about your application.

An application that wants to provide counter data can implement a performance counter to provide the data. When a consumer queries performance data, the HPX runtime system calls the provider to collect the data. The runtime system uses an internal registry to determine which provider to call.

Generally, there are two ways of exposing your own performance counter data: a simple, function-based way and a more complex, but more powerful way of implementing a full performance counter. Both alternatives are described in the following sections.

### Exposing performance counter data using a simple function

The simplest way to expose arbitrary numeric data is to write a function which will then be called whenever a consumer queries this counter. Currently, this type of performance counter can only be used to expose integer values. The expected signature of this function is:

```
std::int64_t some_performance_data(bool reset);
```

The argument `bool reset` (which is supplied by the runtime system when the function is invoked) specifies whether the counter value should be reset after evaluating the current value (if applicable).

For instance, here is such a function returning how often it was invoked:

```
// The atomic variable 'counter' ensures the thread safety of the counter.
boost::atomic<std::int64_t> counter(0);

std::int64_t some_performance_data(bool reset)
{
    std::int64_t result = ++counter;
    if (reset)
        counter = 0;
    return result;
}
```

This example function exposes a linearly-increasing value as our performance data. The value is incremented on each invocation, i.e., each time a consumer requests the counter data of this performance counter.

The next step in exposing this counter to the runtime system is to register the function as a new raw counter type using the HPX API function `hpx::performance_counters::install_counter_type`. A counter type represents certain common characteristics of counters, like their counter type name and any associated description information. The following snippet shows an example of how to register the function `some_performance_data`, which is shown above, for a counter type named "/test/data". This registration has to be executed before any consumer instantiates, and queries an instance of this counter type:

```
#include <hpx/include/performance_counters.hpp>

void register_counter_type()
{
    // Call the HPX API function to register the counter type.
    hpx::performance_counters::install_counter_type(
        "/test/data",                                // counter type name
        &some_performance_data,                      // function providing counter
        ↪data                                         // description text (optional)
        "returns a linearly increasing counter value" // unit of measure (optional)
        );
}
```

Now it is possible to instantiate a new counter instance based on the naming scheme "/test{locality#/\*/total}/data" where \* is a zero-based integer index identifying the *locality* for which the counter instance should be accessed. The function `hpx::performance_counters::install_counter_type` enables users to instantiate exactly one counter instance for each *locality*. Repeated requests to instantiate such a counter will return the same instance, i.e., the instance created for the first request.

If this counter needs to be accessed using the standard *HPX* command line options, the registration has to be performed during application startup, before `hpx_main` is executed. The best way to achieve this is to register an *HPX* startup function using the API function `hpx::register_startup_function` before calling `hpx::init` to initialize the runtime system:

```
int main(int argc, char* argv[])
{
    // By registering the counter type we make it available to any consumer
    // who creates and queries an instance of the type "/test/data".
    //
    // This registration should be performed during startup. The
    // function 'register_counter_type' should be executed as an HPX thread right
    // before hpx_main is executed.
    hpx::register_startup_function(&register_counter_type);

    // Initialize and run HPX.
    return hpx::init(argc, argv);
}
```

Please see the code in `simplest_performance_counter.cpp` for a full example demonstrating this functionality.

### Implementing a full performance counter

Sometimes, the simple way of exposing a single value as a performance counter is not sufficient. For that reason, *HPX* provides a means of implementing full performance counters which support:

- Retrieving the descriptive information about the performance counter
- Retrieving the current counter value
- Resetting the performance counter (value)
- Starting the performance counter
- Stopping the performance counter

- Setting the (initial) value of the performance counter

Every full performance counter will implement a predefined interface:

    std::string const& name, error_code& ec = throws);
} } // namespace hpx::performance_counters

#include <hpx/config/warnings_suffix.hpp>

```

In order to implement a full performance counter, you have to create an *HPX* component exposing this interface. To simplify this task, *HPX* provides a ready-made base class which handles all the boiler plate of creating a component for you. The remainder of this section will explain the process of creating a full performance counter based on the Sine example, which you can find in the directory `examples/performance_counters/sine/`.

The base class is defined in the header file `base_performance_counter.cpp` as:

```

// Copyright (c) 2007-2018 Hartmut Kaiser
//
// SPDX-License-Identifier: BSL-1.0
// Distributed under the Boost Software License, Version 1.0. (See accompanying
// file LICENSE_1_0.txt or copy at http://www.boost.org/LICENSE_1_0.txt)

#pragma once

#include <hpx/config.hpp>

```

(continues on next page)

(continued from previous page)

```

#include <hpx/actions_base/component_action.hpp>
#include <hpx/components_base/component_type.hpp>
#include <hpx/components_base/server/component_base.hpp>

```

i.e., the type `sine_counter` is derived from the base class passing the type as a template argument (please see `simplest_performance_counter.cpp` for the full source code of the counter definition). For more information about this technique (called Curiously Recurring Template Pattern - CRTP), please see for instance the corresponding [Wikipedia article](#)<sup>135</sup>. This base class itself is derived from the `performance_counter` interface described above.

Additionally, a full performance counter implementation not only exposes the actual value but also provides information about:

- The point in time a particular value was retrieved.
- A (sequential) invocation count.
- The actual counter value.
- An optional scaling coefficient.
- Information about the counter status.

## Existing HPX performance counters

The `HPX` runtime system exposes a wide variety of predefined performance counters. These counters expose critical information about different modules of the runtime system. They can help determine system bottlenecks and fine-tune system and application performance.

Table 2.27: AGAS performance counters

Counter type	Counter instance formatting	Description	Parameters
/agas/count/<agas_service> ?? where: <agas_service> is one of the following: <i>primary namespace services</i> : route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, allocate, begin_migration, end_migration <i>component namespace services</i> : bind_prefix, bind_name, resolve_id, unbind_name, iterate_types, get_component_typename, num_localities_type <i>locality namespace services</i> : free, localities, num_localities, num_threads, resolve_locality, resolved_localities <i>symbol namespace services</i> : bind, resolve, unbind, iterate_names, on_symbol_namespace_event	<agas_instance>/total where: <agas_instance> is the name of the <b>AGAS</b> service to query. Currently, this value will be locality#0 where 0 is the root <i>locality</i> (the id of the locality hosting the <b>AGAS</b> service). The value for * can be any <i>locality</i> id for the following <agas_service>: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, bin, resolve, unbind, and iterate_names (only the primary and symbol <b>AGAS</b> service components live on all localities, whereas all other <b>AGAS</b> services are available on locality#0 only).	None	Returns the total number of invocations of the specified <b>AGAS</b> service since its creation.
/agas/<agas_service_category>/count ?? where: <agas_service_category> is one of the following: primary, locality, component or symbol	<agas_instance>/total where: <agas_instance> is the name of the <b>AGAS</b> service to query. Currently, this value will be locality#0 where 0 is the root <i>locality</i> (the id of the <i>locality</i> hosting the <b>AGAS</b> service). Except for <agas_service_category>, primary or symbol for which the value for * can be any <i>locality</i> id (only the primary and symbol <b>AGAS</b> service components live on all localities, whereas all other <b>AGAS</b> services are available on locality#0 only).	None	Returns the overall total number of invocations of all <b>AGAS</b> services provided by the given <b>AGAS</b> service category since its creation.
agas/time/<agas_service> ?? where: <agas_service> is one of the following: <i>primary namespace services</i> : route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, allocate, begin_migration, end_migration <i>component namespace services</i> : bind_prefix, bind_name, resolve_id, unbind_name, iterate_types, get_component_typename, num_localities_type <i>locality namespace services</i> : free, localities, num_localities, num_threads, resolve_locality, resolved_localities <i>symbol namespace services</i> : bind, resolve, unbind, iterate_names,	<agas_instance>/total where: <agas_instance> is the name of the <b>AGAS</b> service to query. Currently, this value will be locality#0 where 0 is the root <i>locality</i> (the id of the <i>locality</i> hosting the <b>AGAS</b> service). The value for * can be any <i>locality</i> id for the following <agas_service>: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, bin, resolve, unbind, and iterate_names (only the primary and symbol <b>AGAS</b> service components live on all localities, whereas all other <b>AGAS</b> services are available on locality#0 only).	None	Returns the overall execution time of the specified <b>AGAS</b> service since its creation (in nanoseconds).

Table 2.28: Parcel layer performance counters

Counter type	Counter instance formatting	Description	Parameters
/data/count/ <connection_type> <operation> ?? where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi	locality#*/ total where: * is the <i>locality</i> id of the <i>locality</i> the overall number of transmitted bytes should be queried for. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the overall number of raw (uncompressed) bytes sent or received (see <operation>, e.g. sent or received) for the specified <connection_type>. The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see <a href="#">CMake variables used to configure HPX</a> for more details.	None
/data/time/ <connection_type> <operation> ?? where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi	locality#*/ total where: * is the <i>locality</i> id of the <i>locality</i> the total transmission time should be queried for. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the total time (in nanoseconds) between the start of each asynchronous transmission operation and the end of the corresponding operation for the specified <connection_type> the given <i>locality</i> (see <operation>, e.g. sent or received). The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see <a href="#">CMake variables used to configure HPX</a> for more details.	None
/serialize/ count/ <connection_type> <operation> ?? where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi	locality#*/ total where: * is the <i>locality</i> id of the <i>locality</i> the overall number of transmitted bytes should be queried for. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the overall number of bytes transferred (see <operation>, e.g. sent or received possibly compressed) for the specified <connection_type> by the given <i>locality</i> . The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI.	If the configuration option -DHPX_WITH_PARCELPORT_ACTION was specified, this counter allows one to specify an optional action name as its parameter. In this case the counter will report the number of bytes transmitted for the given action only.
<b>2.3. Manual</b>	number identifying the <i>locality</i> .	Please see <a href="#">CMake variables used to configure HPX</a> for more details.	<b>173</b>
/serialize/	locality#*/	Returns the overall time spent performing outgoing data se-	If the configura-

Table 2.29: Thread manager performance counters

Counter type	Counter instance formatting	Description	Parameters
/threads/count/ cumulative ??	<p>locality#*/total or locality#*/ worker-thread#*</p> <p>or</p> <p>locality#*/pool#*/ worker-thread#*</p> <p>where:</p> <p>locality#* is defining the <i>locality</i> for which the overall number of retired HPX-threads should be queried for. The <i>locality</i> id (given by * is a (zero based) number identifying the <i>locality</i>.</p> <p><b>pool#*</b> is defining the pool for which the thread count is returned.</p> <p>idle-loop counter should be queried for.</p> <p><b>worker-thread#*</b> is defining the worker thread number (given by * is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option <code>--hpx:threads</code>. If no pool-name is specified the counter refers to the 'default' pool.</p>	<p>Returns the overall number of executed (retired) HPX-threads on the given <i>locality</i> since application start. If the instance name is <i>total</i> the counter returns the accumulated number of retired HPX-threads for all worker threads (cores) on that <i>locality</i>. If the instance name is <i>worker-thread#*</i> the counter will return the overall number of all worker threads separately. This counter is available only if the configuration <code>HPX_THREADS_CUMULATIVE_COUNTS</code> is set to ON (default: ON).</p>	None

Table 2.30: General performance counters exposing characteristics of localities

Counter type	Counter instance formatting	Description	Parameters
/runtime/count/component ??	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i> the number of components should be queried. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the overall number of currently active components of the specified type on the given <i>locality</i> .	The type of the component. This is the string which has been used while registering the component with <i>HPX</i> , e.g. which has been passed as the second parameter to the macro <i>HPX_REGISTER_COMPONENT</i> .
/runtime/count/action-invocation ??	locality#*/total where: * is the <i>locality</i> id of the locality the number of action invocations should be queried. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the overall (local) invocation count of the specified action type on the given <i>locality</i> .	The action type. This is the string which has been used while registering the action with <i>HPX</i> , e.g. which has been passed as the second parameter to the macro <i>HPX_REGISTER_ACTION</i> or <i>HPX_REGISTER_ACTION_ID</i> .
/runtime/count/remote-action-invocation ??	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i> the number of action invocations should be queried. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the overall (remote) invocation count of the specified action type on the given <i>locality</i> .	The action type. This is the string which has been used while registering the action with <i>HPX</i> , e.g. which has been passed as the second parameter to the macro <i>HPX_REGISTER_ACTION</i> or <i>HPX_REGISTER_ACTION_ID</i> .
/runtime/uptime ??	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i> the system uptime should be queried. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the overall time since application start on the given <i>locality</i> in nanoseconds.	None
/runtime/memory/virtual ??	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i> the allocated virtual memory should be queried. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the amount of virtual memory currently allocated by the referenced <i>locality</i> (in bytes).	None
/runtime/memory/resident ??	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i> the allocated resident memory should be queried. The <i>locality</i> id is a (zero based) number identifying the <i>locality</i> .	Returns the amount of resident memory currently allocated by the referenced <i>locality</i> (in bytes).	None
204	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i> identifying the <i>locality</i> .	<b>Chapter 2. What's so special about HPX?</b>	
/runtime/memory/total ??	locality#*/total where: * is the <i>locality</i> id of the <i>locality</i>	Returns the total available <i>locality</i> (in bytes). This counter is	None

Table 2.31: Performance counters exposing PAPI hardware counters

Counter type	Counter instance formatting	Description	Pa-ram-e-ters
/papi/<papi_event> ?? where: <papi_event> is the name of the PAPI event to expose as a performance counter (such as PAPI_SR_INS). Note that the list of available PAPI events changes depending on the used architecture. For a full list of available PAPI events and their (short) description use the --hpx:list-counters and --hpx:papi-event-info=all command line options.	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the <i>locality</i> for which the current accumulated value of all busy-loop counters of all worker threads should be queried. The <i>locality</i> id (given by *) is a (zero based) number identifying the <i>locality</i> . worker-thread#* is defining the worker thread for which the current value of the busy-loop counter should be queried for. The worker thread number (given by the *) is a (zero based) worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option <i>--hpx:threads</i> .	This counter returns the current count of occurrences of the specified PAPI event. This counter is available only if the configuration time constant HPX_WITH_PAPI is set to ON (default: OFF).	None

Table 2.32: Performance counters for general statistics

Counter type	Counter instance formatting	Description	Parameters
/ stat? ??	Any full performance counter average name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.	Returns the current average (mean) value calculated based on the values queried from the underlying counter (the one specified as the instance name).	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.
/ stat? ??	Any full performance counter rollingaverage The referenced performance counter is queried at fixed time intervals as specified by the first parameter.	Returns the current rolling average (mean) value calculated based on the values queried from the underlying counter (the one specified as the instance name).	Any parameter will be interpreted as a list of up to three comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value will be interpreted as the size of the rolling window (the number of latest values to use to calculate the rolling average). The default value for this is 10. The third value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.
/ stat? ??	Any full performance counter stddev name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.	Returns the current standard deviation (stddev) value calculated based on the values queried from the underlying counter (the one specified as the instance name).	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.
/ stat? ??	Any full performance counter rollingvariance The referenced performance counter is queried at fixed time intervals as specified by the first parameter.	Returns the current rolling variance (stddev) value calculated based on the values queried from the underlying counter (the one specified as the instance name).	Any parameter will be interpreted as a list of up to three comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value will be interpreted as the size of the rolling window (the number of latest values to use to calculate the rolling average). The default value for this is 10. The third value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.
/ stat? ??	Any full performance counter median name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.	Returns the current (statistically estimated) median value calculated based on the values queried from the underlying counter (the one specified as the instance name).	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.
206	queried at fixed time intervals as specified by the first parameter.	counter (the one specified as the instance name).	<b>Chapter 2. What's so special about HPX?</b>

Table 2.33: Performance counters for elementary arithmetic operations

Counter type	Counter instance formatting	Description	Parameters
/arithmetics/add ??	None	Returns the sum calculated based on the values queried from the underlying counters (the ones specified as the parameters).	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.
/arithmetics/subtract ??	None	Returns the difference calculated based on the values queried from the underlying counters (the ones specified as the parameters).	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.
/arithmetics/multiply ??	None	Returns the product calculated based on the values queried from the underlying counters (the ones specified as the parameters).	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.
/arithmetics/divide ??	None	Returns the result of division of the values queried from the underlying counters (the ones specified as the parameters).	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.
/arithmetics/mean ??	None	Returns the average value of all values queried from the underlying counters (the ones specified as the parameters).	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.
/arithmetics/variance ??	None	Returns the standard deviation of all values queried from the underlying counters (the ones specified as the parameters).	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.
<b>2.3. Manual</b>			207
/arithmetics/median ??	None	Returns the median value of all values queried from	The parameter will be interpreted as a comma sep-

---

**Note:** The `/arithmetics` counters can consume an arbitrary number of other counters. For this reason those have to be specified as parameters (a comma separated list of counters appended after a '@'). For instance:

```
$ ./bin/hello_world_distributed -t2 \
    --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative \
    --hpx:print-counter=/arithmetics/add@/threads{locality#0/worker-thread#*}/count/
    ↵cumulative
hello world from OS-thread 0 on locality 0
hello world from OS-thread 1 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.515640,[s],25
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.515520,[s],36
/arithmetics/add@/threads{locality#0/worker-thread#*}/count/cumulative,1,0.516445,[s],64
```

---

Since all wildcards in the parameters are expanded, this example is fully equivalent to specifying both counters separately to `/arithmetics/add`:

```
$ ./bin/hello_world_distributed -t2 \
    --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative \
    --hpx:print-counter=/arithmetics/add@
        /threads{locality#0/worker-thread#0}/count/cumulative, \
        /threads{locality#0/worker-thread#1}/count/cumulative
```

---

Table 2.34: Performance counters tracking parcel coalescing

Counter type	Description	Parameters
/ locality#*/coalescing/count/where: parcel's is the <i>locality</i> ? ??	Returns the number of parcels handled by the message handler associated with the action which is given by the counter parameter.	The action type. This is the string which has been used while registering the action with <i>HPX</i> , e.g. which has been passed as the second parameter to the macro <i>HPX_REGISTER_ACTION</i> or <i>HPX_REGISTER_ACTION_ID</i> .
/ locality#*/coalescing/count/where: message's is the <i>locality</i> ? ??	Returns the number of messages generated by the message handler associated with the action which is given by the counter parameter.	The action type. This is the string which has been used while registering the action with <i>HPX</i> , e.g. which has been passed as the second parameter to the macro <i>HPX_REGISTER_ACTION</i> or <i>HPX_REGISTER_ACTION_ID</i> .
/ locality#*/coalescing/count/where: average-parcels-per-message? ??	Returns the average number of parcels sent in a message generated by the message handler associated with the action which is given by the <i>message</i> parameter.	The action type. This is the string which has been used while registering the action with <i>HPX</i> , e.g. which has been passed as the second parameter to the macro <i>HPX_REGISTER_ACTION</i> or <i>HPX_REGISTER_ACTION_ID</i>
2.3. Manual locality#*/coalescing/time/where: average-parcel-karrival	Returns the average time between arriving parcels for the action which is given by the counter parameter.	The action type. This is the string which has been used while registering the action with <i>HPX</i> , e.g. which has been passed as the second parameter

---

**Note:** The performance counters related to *parcel* coalescing are available only if the configuration time constant `HPX_WITH_PARCEL_COALESCING` is set to ON (default: ON). However, even in this case it will be available only for actions that are enabled for parcel coalescing (see the macros `HPX_ACTIONUSES_MESSAGE_COALESCING` and `HPX_ACTIONUSES_MESSAGE_COALESCING_NOTHROW`).

---

## APEX integration

*HPX* provides integration with [APEX](#)<sup>137</sup>, which is a framework for application profiling using task timers and various performance counters Huck *et al.*<sup>140</sup>. It can be added as a git submodule by turning on the option `HPX_WITH_APEX:BOOL` during CMake configuration. [TAU](#)<sup>138</sup> is an optional dependency when using APEX.

To build *HPX* with APEX, add `HPX_WITH_APEX=ON`, and, optionally, `TAU_ROOT=$PATH_TO_TAU` to your CMake configuration. In addition, you can override the tag used for APEX with the `HPX_WITH_APEX_TAG` option. Please see the [APEX HPX documentation](#)<sup>139</sup> for detailed instructions on using APEX with *HPX*.

## References

### 2.3.13 *HPX* runtime and resources

#### *HPX* thread scheduling policies

The *HPX* runtime has five thread scheduling policies: local-priority, static-priority, local, static and abp-priority. These policies can be specified from the command line using the command line option `--hpx:queuing`. In order to use a particular scheduling policy, the runtime system must be built with the appropriate scheduler flag turned on (e.g. `cmake -DHPX_THREAD_SCHEDULERS=local`, see [CMake variables used to configure HPX](#) for more information).

#### Priority local scheduling policy (default policy)

The priority local scheduling policy maintains one queue per operating system (OS) thread. The OS thread pulls its work from this queue. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by any of the OS threads before any other work is executed. When a queue is empty, work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work.

For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on, work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler is enabled at build time by default using the FIFO (first-in-first-out) queing policy. This policy can be invoked using `--hpx:queuing=local-priority-fifo`. The scheduler can also be enabled using the LIFO (last-in-first-out) policy. This is not the default policy and must be invoked using the command line option `--hpx:queuing=local-priority-lifo`.

<sup>138</sup> <https://www.cs.uoregon.edu/research/tau/home.php>

<sup>139</sup> <https://uo-oaciss.github.io/apex/usage/#hpx-louisiana-state-university>

## Static priority scheduling policy

- invoke using: `--hpx:queuing=static-priority` (or `-qs`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static-priority`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

## Local scheduling policy

- invoke using: `--hpx:queuing=local` (or `-ql`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=local`

The local scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads).

## Static scheduling policy

- invoke using: `--hpx:queuing=static`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

## Priority ABP scheduling policy

- invoke using: `--hpx:queuing=abp-priority-fifo`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=abp-priority`

Priority ABP policy maintains a double ended lock free queue for each OS thread. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by the first OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work. For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). In order to use the LIFO policy use the command line option `--hpx:queuing=abp-priority-lifo`.

## The HPX resource partitioner

The *HPX* resource partitioner lets you take the execution resources available on a system—processing units, cores, and numa domains—and assign them to thread pools. By default *HPX* creates a single thread pool name `default`. While this is good for most use cases, the resource partitioner lets you create multiple thread pools with custom resources and options.

Creating custom thread pools is useful for cases where you have tasks which absolutely need to run without interference from other tasks. An example of this is when using [MPI](#)<sup>141</sup> for distribution instead of the built-in mechanisms in

---

<sup>141</sup> [https://en.wikipedia.org/wiki/Message\\_Passing\\_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

*HPX* (useful in legacy applications). In this case one can create a thread pool containing a single thread for MPI communication. MPI tasks will then always run on the same thread, instead of potentially being stuck in a queue behind other threads.

Note that *HPX* thread pools are completely independent from each other in the sense that task stealing will never happen between different thread pools. However, tasks running on a particular thread pool can schedule tasks on another thread pool.

---

**Note:** It is simpler in some situations to schedule important tasks with high priority instead of using a separate thread pool.

---

## Using the resource partitioner

The `hpx::resource::partitioner` is now created during *HPX* runtime initialization without explicit action needed from the user. To specify some of the initialization parameters you can use the `hpx::init_params`.

The resource partitioner callback is the interface to add thread pools to the *HPX* runtime and to assign resources to the thread pools. In order to create custom thread pools you can specify the resource partitioner callback `hpx::init_params::rp_callback` which will be called once the resource partitioner will be created , see the example below. You can also specify other parameters, see `hpx::init_params`.

To add a thread pool use the `hpx::resource::partitioner::create_thread_pool` method. If you simply want to use the default scheduler and scheduler options, it is enough to call `rp.create_thread_pool("my-thread-pool")`.

Then, to add resources to the thread pool you can use the `hpx::resource::partitioner::add_resource` method. The resource partitioner exposes the hardware topology retrieved using [Portable Hardware Locality \(HWLOC\)](#)<sup>142</sup> and lets you iterate through the topology to add the wanted processing units to the thread pool. Below is an example of adding all processing units from the first NUMA domain to a custom thread pool, unless there is only one NUMA domain in which case we leave the first processing unit for the default thread pool:

---

**Note:** Whatever processing units are not assigned to a thread pool by the time `hpx::init` is called will be added to the default thread pool. It is also possible to explicitly add processing units to the default thread pool, and to create the default thread pool manually (in order to e.g. set the scheduler type).

---

**Tip:** The command line option `--hpx:print-bind` is useful for checking that the thread pools have been set up the way you expect.

---

## Difference between the old and new version

In the old version, you had to create an instance of the `resource_partitioner` with `argc` and `argv`.

```
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    hpx::init();
}
```

---

<sup>142</sup> <https://www.open-mpi.org/projects/hwloc/>

From HPX 1.5.0 onwards, you just pass `argc` and `argv` to `hpx::init()` or `hpx::start()` for the binding options to be parsed by the resource partitioner.

```
int main(int argc, char** argv)
{
    hpx::init_params init_args;
    hpx::init(argc, argv, init_args);
}
```

In the old version, when creating a custom thread pool, you just called the utilities on the resource partitioner instantiated previously.

```
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);

    rp.create_thread_pool("my-thread-pool");

    bool one numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }

    hpx::init();
}
```

You now specify the resource partitioner callback which will tie the resources to the resource partitioner created during runtime initialization.

```
void init_resource_partitioner_handler(hpx::resource::partitioner& rp)
{
    rp.create_thread_pool("my-thread-pool");

    bool one numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
```

(continues on next page)

(continued from previous page)

```

for (const hpx::resource::pu& p : c.pus())
{
    if (one_numa_domain && !skipped_first_pu)
    {
        skipped_first_pu = true;
        continue;
    }

    rp.add_resource(p, "my-thread-pool");
}
}

int main(int argc, char* argv[])
{
    hpx::init_params init_args;
    init_args.rp_callback = &init_resource_partitioner_handler;

    hpx::init(argc, argv, init_args);
}

```

## Advanced usage

It is possible to customize the built in schedulers by passing scheduler options to `hpx::resource::partitioner::create_thread_pool`. It is also possible to create and use custom schedulers.

---

**Note:** It is not recommended to create your own scheduler. The *HPX* developers use this to experiment with new scheduler designs before making them available to users via the standard mechanisms of choosing a scheduler (command line options). If you would like to experiment with a custom scheduler the resource partitioner example `shared_priority_queue_scheduler.cpp` contains a fully implemented scheduler with logging, etc. to make exploration easier.

---

To choose a scheduler and custom mode for a thread pool, pass additional options when creating the thread pool like this:

```

rp.create_thread_pool("my-thread-pool",
    hpx::resource::policies::local_priority_lifo,
    hpx::policies::scheduler_mode(
        hpx::policies::scheduler_mode::default_ |
        hpx::policies::scheduler_mode::enable_elasticity));

```

The available schedulers are documented here: `hpx::resource::scheduling_policy`, and the available scheduler modes here: `hpx::threads::policies::scheduler_mode`. Also see the examples folder for examples of advanced resource partitioner usage: `simple_resource_partitioner.cpp` and `oversubscribing_resource_partitioner.cpp`.

## 2.3.14 Miscellaneous

### Error handling

Like in any other asynchronous invocation scheme, it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In *HPX* all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation *locality*, where it will be rethrown during synchronization with the calling thread.

The source code for this example can be found here: `error_handling.cpp`.

### Working with exceptions

For the following description assume that the function `raise_exception()` is executed by invoking the plain action `raise_exception_type`.

```
#include <hpx/iostream.hpp>
#include <hpx/modules/runtime_local.hpp>

//[error_handling_raise_exception
void raise_exception()
```

The exception is thrown using the macro `HPX_THROW_EXCEPTION`. The type of the thrown exception is `hpx::exception`. This associates additional diagnostic information with the exception, such as file name and line number, *locality* id and thread id, and stack backtrace from the point where the exception was thrown.

Any exception thrown during the execution of an action is transferred back to the (asynchronous) invocation site. It will be rethrown in this context when the calling thread tries to wait for the result of the action by invoking either `future<>::get()` or the synchronous action invocation wrapper as shown here:

```
{
    /////////////////////////////////
    // Error reporting using exceptions
    //#[exception_diagnostic_information
    hpx::cout << "Error reporting using exceptions\n";
    try
    {
        // invoke raise_exception() which throws an exception
        raise_exception_action do_it;
        do_it(hpx::find_here());
    }
    catch (hpx::exception const& e)
    {
        // Print just the essential error information.
        hpx::cout << "caught exception: " << e.what() << "\n\n";
```

---

**Note:** The exception is transferred back to the invocation site even if it is executed on a different *locality*.

---

Additionally, this example demonstrates how an exception thrown by an (possibly remote) action can be handled. It shows the use of `hpx::diagnostic_information`, which retrieves all available diagnostic information from the exception as a formatted string. This includes, for instance, the name of the source file and line number, the sequence number of the OS thread and the *HPX* thread id, the *locality* id and the stack backtrace of the point where the original exception was thrown.

Under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, *HPX* exposes a set of lower-level functions as demonstrated in the following code snippet:

```
}

hpx::cout << std::flush;
//]

// Detailed error reporting using exceptions
//[exception_diagnostic_elements
hpx::cout << "Detailed error reporting using exceptions\n";
try
{
    // Invoke raise_exception() which throws an exception.
    raise_exception_action do_it;
    do_it(hpx::find_here());
}
catch (hpx::exception const& e)
{
    // Print the elements of the diagnostic information separately.
    hpx::cout << "{what}: " << hpx::get_error_what(e) << "\n";
    hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(e)
        << "\n";
    hpx::cout << "{hostname}: " << hpx::get_error_host_name(e) << "\n";
    hpx::cout << "{pid}: " << hpx::get_error_process_id(e) << "\n";
    hpx::cout << "{function}: " << hpx::get_error_function_name(e)
        << "\n";
    hpx::cout << "{file}: " << hpx::get_error_file_name(e) << "\n";
    hpx::cout << "{line}: " << hpx::get_error_line_number(e) << "\n";
    hpx::cout << "{os-thread}: " << hpx::get_error_os_thread(e) << "\n";
```

## Working with error codes

Most of the API functions exposed by *HPX* can be invoked in two different modes. By default those will throw an exception on error as described above. However, sometimes it is desirable not to throw an exception in case of an error condition. In this case an object instance of the `hpx::error_code` type can be passed as the last argument to the API function. In case of an error, the error condition will be returned in that `hpx::error_code` instance. The following example demonstrates extracting the full diagnostic information without exception handling:

```
hpx::cout << "{stack-trace}: " << hpx::get_error_backtrace(e)
    << "\n";
    hpx::cout << "{env}: " << hpx::get_error_env(e) << "\n";
}

hpx::cout << std::flush;
//]

///////////////////////////////
// Error reporting using error code
{
    //[error_handling_diagnostic_information
    hpx::cout << "Error reporting using error code\n";

    // Create a new error_code instance.
```

(continues on next page)

(continued from previous page)

```

    hpx::error_code ec;

    // If an instance of an error_code is passed as the last argument while
    // invoking the action, the function will not throw in case of an error
    // but store the error information in this error_code instance instead.
    raise_exception_action do_it;
    do_it(hpx::find_here(), ec);

```

**Note:** The error information is transferred back to the invocation site even if it is executed on a different *locality*.

This example shows how an error can be handled without having to resolve to exceptions and that the returned `hpx::error_code` instance can be used in a very similar way as the `hpx::exception` type above. Simply pass it to the `hpx::diagnostic_information`, which retrieves all available diagnostic information from the error code instance as a formatted string.

As for handling exceptions, when working with error codes, under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, *HPX* exposes a set of lower-level functions usable with error codes as demonstrated in the following code snippet:

```

    // the exception.
    hpx::cout << "diagnostic information:"
                  << hpx::diagnostic_information(ec) << "\n";
}

hpx::cout << std::flush;
//]
}

// Detailed error reporting using error code
{
    //#[error_handling_diagnostic_elements
    hpx::cout << "Detailed error reporting using error code\n";

    // Create a new error_code instance.
    hpx::error_code ec;

    // If an instance of an error_code is passed as the last argument while
    // invoking the action, the function will not throw in case of an error
    // but store the error information in this error_code instance instead.
    raise_exception_action do_it;
    do_it(hpx::find_here(), ec);

    if (ec)
    {
        // Print the elements of the diagnostic information separately.
        hpx::cout << "{what}: " << hpx::get_error_what(ec) << "\n";
        hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(ec)
                  << "\n";
        hpx::cout << "{hostname}: " << hpx::get_error_host_name(ec)
                  << "\n";
        hpx::cout << "{pid}: " << hpx::get_error_process_id(ec) << "\n";
    }
}

```

(continues on next page)

<code>hpx::cout &lt;&lt; "{function}: " &lt;&lt; hpx::get_error_function_name(ec)</code>
--

For more information please refer to the documentation of `hpx::get_error_what`, `hpx::get_error_locality_id`, `hpx::get_error_host_name`, `hpx::get_error_process_id`, `hpx::get_error_function_name`, `hpx::get_error_file_name`, `hpx::get_error_line_number`, `hpx::get_error_os_thread`, `hpx::get_error_thread_id`, `hpx::get_error_thread_description`, `hpx::get_error_backtrace`, `hpx::get_error_env`, and `hpx::get_error_state`.

## Lightweight error codes

Sometimes it is not desirable to collect all the ambient information about the error at the point where it happened as this might impose too much overhead for simple scenarios. In this case, *HPX* provides a lightweight error code facility that will hold the error code only. The following snippet demonstrates its use:

```

        hpx::cout << "{thread-id}: " << std::hex
                    << hpx::get_error_thread_id(ec) << "\n";
        hpx::cout << "{thread-description}: "
                    << hpx::get_error_thread_description(ec) << "\n\n";
        hpx::cout << "{state}: " << std::hex << hpx::get_error_state(ec)
                    << "\n";
        hpx::cout << "{stack-trace}: " << hpx::get_error_backtrace(ec)
                    << "\n";
        hpx::cout << "{env}: " << hpx::get_error_env(ec) << "\n";
    }

    hpx::cout << std::flush;
    //]
}

// Error reporting using lightweight error code
{
    //[[lightweight_error_handling_diagnostic_information
    hpx::cout << "Error reporting using an lightweight error code\n";

    // Create a new error_code instance.
}

```

All functions that retrieve other diagnostic elements from the `hpx::error_code` will fail if called with a lightweight `error_code` instance.

## Utilities in HPX

In order to ease the burden of programming, *HPX* provides several utilities to users. The following section documents those facilities.

### Checkpoint

See *checkpoint*.

### The HPX I/O-streams component

The *HPX* I/O-streams subsystem extends the standard C++ output streams `std::cout` and `std::cerr` to work in the distributed setting of an *HPX* application. All of the output streamed to `hpx::cout` will be dispatched to `std::cout` on the console *locality*. Likewise, all output generated from `hpx::cerr` will be dispatched to `std::cerr` on the console *locality*.

---

**Note:** All existing standard manipulators can be used in conjunction with `hpx::cout` and `hpx::cerr`.

---

In order to use either `hpx::cout` or `hpx::cerr`, application codes need to `#include <hpx/include/iostreams.hpp>`. For an example, please see the following ‘Hello world’ program:

```
// Copyright (c) 2007-2012 Hartmut Kaiser
//
// SPDX-License-Identifier: BSL-1.0
// Distributed under the Boost Software License, Version 1.0. (See accompanying
// file LICENSE_1_0.txt or copy at http://www.boost.org/LICENSE_1_0.txt)

///////////////////////////////
// The purpose of this example is to execute a HPX-thread printing
// "Hello World!" once. That's all.

//[hello_world_1_getting_started
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
//]
```

Additionally, those applications need to link with the `iostreams` component. When using CMake this can be achieved by using the `COMPONENT_DEPENDENCIES` parameter; for instance:

```
include(HPX_AddExecutable)

add_hpx_executable(
```

(continues on next page)

(continued from previous page)

```
hello_world
SOURCES hello_world.cpp
COMPONENT_DEPENDENCIES iostreams
)
```

**Note:** The `hpx::cout` and `hpx::cerr` streams buffer all output locally until a `std::endl` or `std::flush` is encountered. That means that no output will appear on the console as long as either of these is explicitly used.

## 2.3.15 Troubleshooting

### Common issues

This section contains commonly encountered problems when compiling or using HPX.

See also the closed issues on [GitHub<sup>143</sup>](#) to find out how other people resolved a similar problem. If nothing of that works, you can also open a new issue on [GitHub<sup>144</sup>](#) or contact us using one the options found in [Support for deploying and using HPX<sup>145</sup>](#).

#### Undefined reference to `hpx::cout`

You may see a linker error message that looks a bit like this:

```
hello_world.cpp:(.text+0x5aa): undefined reference to `hpx::cout'
```

This usually happens if you are trying to use *HPX* iostreams functionality such as `hpx::cout` but are not linking against it. The iostreams functionality is not part of the core *HPX* library, and must be linked to explicitly. Typically this can be solved by adding `COMPONENT_DEPENDENCIES iostreams` to a call to `add_hpx_library/add_hpx_executable/hpx_setup_target` if using CMake. See [Creating HPX projects](#) for more details.

#### Fail compiling for examples with `hpx::future` and `co_await`

You may see an error message that looks a bit like this:

```
error: coroutines require a traits template; cannot find 'std::coroutine_traits'
```

This can be resolved by using `-DHFX_WITH_CXX_STANDARD=20` to the `cmake` command line. Note that a compiler that supports C++20 is needed.

See also the corresponding closed Issue #[5784<sup>146</sup>](#).

<sup>143</sup> <https://github.com/STELLAR-GROUP/hpx/issues?q=is%3Aissue+is%3Aclosed>

<sup>144</sup> <https://github.com/STELLAR-GROUP/hpx/issues>

<sup>145</sup> <https://github.com/STELLAR-GROUP/hpx/blob/master/.github/SUPPORT.md>

<sup>146</sup> <https://github.com/STELLAR-GROUP/hpx/issues/5784>

## Build fails with ASIO error

You may see an error message that looks a bit like this:

```
Cannot open include file asio/io_context.hpp
```

This can be resolved by using `-DHPX_WITH_FETCH_ASIO=ON` to the cmake command line.

See also the corresponding closed Issue #5404<sup>147</sup> for more information.

## Build fails with TCMalloc error

You may see an error message that looks a bit like this:

```
Could NOT find TCMalloc (missing: TCMALLOC_LIBRARY TCMALLOC_INCLUDE_DIR)
ERROR: HPX_WITH_MALLOC was set to tcmalloc, but tcmalloc could not be
found. Valid options for HPX_WITH_MALLOC are: system, tcmalloc, jemalloc,
mimalloc, tbbmalloc, and custom
```

This can be resolved either by defining `HPX_WITH_MALLOC=system` or by installing TCMalloc. This error occurs when users don't specify an option for `HPX_WITH_MALLOC`; in that case, `HPX` will be looking `tcmalloc`, which is the default value.

## Useful suggestions

### Reducing compilation time

If you want to significantly reduce compilation time, you can just use the local part of `HPX` for parallelism by disabling the distributed functionality. Moreover, you can avoid compiling examples. These can be done with the following flags:

```
-DHPX_WITH_NETWORKING=OFF
-DHPX_WITH_DISTRIBUTED_RUNTIME=OFF
-DHPX_WITH_EXAMPLES=OFF
-DHPX_WITH_TESTS=OFF
```

### Linking `HPX` to your application

If you want to avoid installing and linking `HPX`, you can just build `HPX` and then use the following flag on your `HPX` application CMake configuration:

```
-DHPX_DIR=<build_dir>/lib/cmake/HPX
```

---

**Note:** For this to work you need not to specify `-DCMAKE_INSTALL_PREFIX` when building `HPX`.

---

<sup>147</sup> <https://github.com/STELLAR-GROUP/hpx/issues/5404>

## HPX-application build type conformance

Your application's build type should align with the HPX build type. For example, if you specified `-DCMAKE_BUILD_TYPE=Debug` during the *HPX* compilation, then your application needs to be compiled with the same flag. We recommend keeping a separate build folder for different build types and just point accordingly to the type you want by using `-DHPX_DIR=<build_dir>/lib/cmake/HPX`.

## 2.4 Terminology

This section gives definitions for some of the terms used throughout the *HPX* documentation and source code.

**Locality** A locality in *HPX* describes a synchronous domain of execution, or the domain of bounded upper response time. This normally is just a single node in a cluster or a NUMA domain in a SMP machine.

### Active Global Address Space

**AGAS** *HPX* incorporates a global address space. Any executing thread can access any object within the domain of the parallel application with the caveat that it must have appropriate access privileges. The model does not assume that global addresses are cache coherent; all loads and stores will deal directly with the site of the target object. All global addresses within a Synchronous Domain are assumed to be cache coherent for those processor cores that incorporate transparent caches. The Active Global Address Space used by *HPX* differs from research PGAS<sup>148</sup> models. Partitioned Global Address Space is passive in their means of address translation. Copy semantics, distributed compound operations, and affinity relationships are some of the global functionality supported by AGAS.

**Process** The concept of the “process” in *HPX* is extended beyond that of either sequential execution or communicating sequential processes. While the notion of process suggests action (as do “function” or “subroutine”) it has a further responsibility of context, that is, the logical container of program state. It is this aspect of operation that process is employed in *HPX*. Furthermore, referring to “parallel processes” in *HPX* designates the presence of parallelism within the context of a given process, as well as the coarse grained parallelism achieved through concurrency of multiple processes of an executing user job. *HPX* processes provide a hierarchical name space within the framework of the active global address space and support multiple means of internal state access from external sources.

**Parcel** The Parcel is a component in *HPX* that communicates data, invokes an action at a distance, and distributes flow-control through the migration of continuations. Parcels bridge the gap of asynchrony between synchronous domains while maintaining symmetry of semantics between local and global execution. Parcels enable message-driven computation and may be seen as a form of “active messages”. Other important forms of message-driven computation predating active messages include dataflow tokens<sup>149</sup>, the J-machine’s<sup>150</sup> support for remote method instantiation, and at the coarse grained variations of Unix remote procedure calls, among others. This enables work to be moved to the data as well as performing the more common action of bringing data to the work. A parcel can cause actions to occur remotely and asynchronously, among which are the creation of threads at different system nodes or synchronous domains.

### Local Control Object

### Lightweight Control Object

**LCO** A local control object (sometimes called a lightweight control object) is a general term for the synchronization mechanisms used in *HPX*. Any object implementing a certain concept can be seen as an LCO. This concepts encapsulates the ability to be triggered by one or more events which when taking the object into a predefined state will cause a thread to be executed. This could either create a new thread or resume an existing thread.

<sup>148</sup> <https://www.pgas.org/>

<sup>149</sup> [http://en.wikipedia.org/wiki/Dataflow\\_architecture](http://en.wikipedia.org/wiki/Dataflow_architecture)

<sup>150</sup> <http://en.wikipedia.org/wiki/J%20Machine>

The LCO is a family of synchronization functions potentially representing many classes of synchronization constructs, each with many possible variations and multiple instances. The LCO is sufficiently general that it can subsume the functionality of conventional synchronization primitives such as spinlocks, mutexes, semaphores, and global barriers. However due to the rich concept an LCO can represent powerful synchronization and control functionality not widely employed, such as dataflow and futures (among others), which open up enormous opportunities for rich diversity of distributed control and operation.

See [Using LCOs](#) for more details on how to use LCOs in *HPX*.

**Action** An action is a function that can be invoked remotely. In *HPX* a plain function can be made into an action using a macro. See [Applying actions](#) for details on how to use actions in *HPX*.

**Component** A component is a C++ object which can be accessed remotely. A component can also contain member functions which can be invoked remotely. These are referred to as component actions. See [Writing components](#) for details on how to use components in *HPX*.

## 2.5 Why *HPX*?

Current advances in high performance computing (HPC) continue to suffer from the issues plaguing parallel computation. These issues include, but are not limited to, ease of programming, inability to handle dynamically changing workloads, scalability, and efficient utilization of system resources. Emerging technological trends such as multi-core processors further highlight limitations of existing parallel computation models. To mitigate the aforementioned problems, it is necessary to rethink the approach to parallelization models. ParalleX contains mechanisms such as multi-threading, *parcels*, *global name space* support, percolation and *local control objects (LCO)*. By design, ParalleX overcomes limitations of current models of parallelism by alleviating contention, latency, overhead and starvation. With ParalleX, it is further possible to increase performance by at least an order of magnitude on challenging parallel algorithms, e.g., dynamic directed graph algorithms and adaptive mesh refinement methods for astrophysics. An additional benefit of ParalleX is fine-grained control of power usage, enabling reductions in power consumption.

### 2.5.1 ParalleX—a new execution model for future architectures

ParalleX is a new parallel execution model that offers an alternative to the conventional computation models, such as message passing. ParalleX distinguishes itself by:

- Split-phase transaction model
- Message-driven
- Distributed shared memory (not cache coherent)
- Multi-threaded
- Futures synchronization
- *Local Control Objects (LCOs)*
- Synchronization for anonymous producer-consumer scenarios
- Percolation (pre-staging of task data)

The ParalleX model is intrinsically latency hiding, delivering an abundance of variable-grained parallelism within a hierarchical namespace environment. The goal of this innovative strategy is to enable future systems delivering very high efficiency, increased scalability and ease of programming. ParalleX can contribute to significant improvements in the design of all levels of computing systems and their usage from application algorithms and their programming languages to system architecture and hardware design together with their supporting compilers and operating system software.

## 2.5.2 What is HPX?

High Performance ParalleX (*HPX*) is the first runtime system implementation of the ParalleX execution model. The *HPX* runtime software package is a modular, feature-complete, and performance-oriented representation of the ParalleX execution model targeted at conventional parallel computing architectures, such as SMP nodes and commodity clusters. It is academically developed and freely available under an open source license. We provide *HPX* to the community for experimentation and application to achieve high efficiency and scalability for dynamic adaptive and irregular computational problems. *HPX* is a C++ library that supports a set of critical mechanisms for dynamic adaptive resource management and lightweight task scheduling within the context of a global address space. It is solidly based on many years of experience in writing highly parallel applications for HPC systems.

The two-decade success of the communicating sequential processes (CSP) execution model and its message passing interface (MPI) programming model have been seriously eroded by challenges of power, processor core complexity, multi-core sockets, and heterogeneous structures of GPUs. Both efficiency and scalability for some current (strong scaled) applications and future Exascale applications demand new techniques to expose new sources of algorithm parallelism and exploit unused resources through adaptive use of runtime information.

The ParalleX execution model replaces CSP to provide a new computing paradigm embodying the governing principles for organizing and conducting highly efficient scalable computations greatly exceeding the capabilities of today's problems. *HPX* is the first practical, reliable, and performance-oriented runtime system incorporating the principal concepts of the ParalleX model publicly provided in open source release form.

*HPX* is designed by the STE||AR<sup>151</sup> Group (Systems Technology, Emergent Parallelism, and Algorithm Research) at Louisiana State University (LSU)<sup>152</sup>'s Center for Computation and Technology (CCT)<sup>153</sup> to enable developers to exploit the full processing power of many-core systems with an unprecedented degree of parallelism. STE||AR<sup>154</sup> is a research group focusing on system software solutions and scientific application development for hybrid and many-core hardware architectures.

For more information about the STE||AR<sup>155</sup> Group, see *People*.

## 2.5.3 What makes our systems slow?

Estimates say that we currently run our computers at well below 100% efficiency. The theoretical peak performance (usually measured in FLOPS<sup>156</sup>—floating point operations per second) is much higher than any practical peak performance reached by any application. This is particularly true for highly parallel hardware. The more hardware parallelism we provide to an application, the better the application must scale in order to efficiently use all the resources of the machine. Roughly speaking, we distinguish two forms of scalability: strong scaling (see Amdahl's Law<sup>157</sup>) and weak scaling (see Gustafson's Law<sup>158</sup>). Strong scaling is defined as how the solution time varies with the number of processors for a fixed **total** problem size. It gives an estimate of how much faster we can solve a particular problem by throwing more resources at it. Weak scaling is defined as how the solution time varies with the number of processors for a fixed problem size **per processor**. In other words, it defines how much more data can we process by using more hardware resources.

In order to utilize as much hardware parallelism as possible an application must exhibit excellent strong and weak scaling characteristics, which requires a high percentage of work executed in parallel, i.e., using multiple threads of execution. Optimally, if you execute an application on a hardware resource with N processors it either runs N times faster or it can handle N times more data. Both cases imply 100% of the work is executed on all available processors in parallel. However, this is just a theoretical limit. Unfortunately, there are more things that limit scalability, mostly

---

<sup>151</sup> <https://stellar-group.org>

<sup>152</sup> <https://www.lsu.edu>

<sup>153</sup> <https://www.cct.lsu.edu>

<sup>154</sup> <https://stellar-group.org>

<sup>155</sup> <https://stellar-group.org>

<sup>156</sup> <http://en.wikipedia.org/wiki/FLOPS>

<sup>157</sup> [http://en.wikipedia.org/wiki/Amdahl%27s\\_law](http://en.wikipedia.org/wiki/Amdahl%27s_law)

<sup>158</sup> [http://en.wikipedia.org/wiki/Gustafson%27s\\_law](http://en.wikipedia.org/wiki/Gustafson%27s_law)

inherent to the hardware architectures and the programming models we use. We break these limitations into four fundamental factors that make our systems *SLOW*:

- Starvation occurs when there is insufficient concurrent work available to maintain high utilization of all resources.
- Latencies are imposed by the time-distance delay intrinsic to accessing remote resources and services.
- Overhead is work required for the management of parallel actions and resources on the critical execution path, which is not necessary in a sequential variant.
- Waiting for contention resolution is the delay due to the lack of availability of oversubscribed shared resources.

Each of those four factors manifests itself in multiple and different ways; each of the hardware architectures and programming models expose specific forms. However, the interesting part is that all of them are limiting the scalability of applications no matter what part of the hardware jungle we look at. Hand-helds, PCs, supercomputers, or the cloud, all suffer from the reign of the 4 horsemen: Starvation, Latency, Overhead, and Contention. This realization is very important as it allows us to derive the criteria for solutions to the scalability problem from first principles, and it allows us to focus our analysis on very concrete patterns and measurable metrics. Moreover, any derived results will be applicable to a wide variety of targets.

## 2.5.4 Technology demands new response

Today's computer systems are designed based on the initial ideas of John von Neumann<sup>159</sup>, as published back in 1945, and later extended by the Harvard architecture<sup>160</sup>. These ideas form the foundation, the execution model, of computer systems we use currently. However, a new response is required in the light of the demands created by today's technology.

So, what are the overarching objectives for designing systems allowing for applications to scale as they should? In our opinion, the main objectives are:

- Performance: as previously mentioned, scalability and efficiency are the main criteria people are interested in.
- Fault tolerance: the low expected mean time between failures (MTBF<sup>161</sup>) of future systems requires embracing faults, not trying to avoid them.
- Power: minimizing energy consumption is a must as it is one of the major cost factors today, and will continue to rise in the future.
- Generality: any system should be usable for a broad set of use cases.
- Programmability: for programmer this is a very important objective, ensuring long term platform stability and portability.

What needs to be done to meet those objectives, to make applications scale better on tomorrow's architectures? Well, the answer is almost obvious: we need to devise a new execution model—a set of governing principles for the holistic design of future systems—targeted at minimizing the effect of the outlined **SLOW** factors. Everything we create for future systems, every design decision we make, every criteria we apply, have to be validated against this single, uniform metric. This includes changes in the hardware architecture we prevalently use today, and it certainly involves new ways of writing software, starting from the operating system, runtime system, compilers, and at the application level. However, the key point is that all those layers have to be co-designed; they are interdependent and cannot be seen as separate facets. The systems we have today have been evolving for over 50 years now. All layers function in a certain way, relying on the other layers to do so. But we do not have the time to wait another 50 years for a new coherent system to evolve. The new paradigms are needed now—therefore, co-design is the key.

<sup>159</sup> <http://qss.stanford.edu/~godfrey/vonNeumann/vnedvac.pdf>

<sup>160</sup> [http://en.wikipedia.org/wiki/Harvard\\_architecture](http://en.wikipedia.org/wiki/Harvard_architecture)

<sup>161</sup> [http://en.wikipedia.org/wiki/Mean\\_time\\_between\\_failures](http://en.wikipedia.org/wiki/Mean_time_between_failures)

## 2.5.5 Governing principles applied while developing HPX

As it turns out, we do not have to start from scratch. Not everything has to be invented and designed anew. Many of the ideas needed to combat the 4 horsemen already exist, many for more than 30 years. All it takes is to gather them into a coherent approach. We'll highlight some of the derived principles we think to be crucial for defeating **SLOW**. Some of those are focused on high-performance computing, others are more general.

### Focus on latency hiding instead of latency avoidance

It is impossible to design a system exposing zero latencies. In an effort to come as close as possible to this goal many optimizations are mainly targeted towards minimizing latencies. Examples for this can be seen everywhere, such as low latency network technologies like InfiniBand<sup>162</sup>, caching memory hierarchies in all modern processors, the constant optimization of existing MPI<sup>163</sup> implementations to reduce related latencies, or the data transfer latencies intrinsic to the way we use GPGPUs<sup>164</sup> today. It is important to note that existing latencies are often tightly related to some resource having to wait for the operation to be completed. At the same time it would be perfectly fine to do some other, unrelated work in the meantime, allowing the system to hide the latencies by filling the idle-time with useful work. Modern systems already employ similar techniques (pipelined instruction execution in the processor cores, asynchronous input/output operations, and many more). What we propose is to go beyond anything we know today and to make latency hiding an intrinsic concept of the operation of the whole system stack.

### Embrace fine-grained parallelism instead of heavyweight threads

If we plan to hide latencies even for very short operations, such as fetching the contents of a memory cell from main memory (if it is not already cached), we need to have very lightweight threads with extremely short context switching times, optimally executable within one cycle. Granted, for mainstream architectures, this is not possible today (even if we already have special machines supporting this mode of operation, such as the Cray XMT<sup>165</sup>). For conventional systems, however, the smaller the overhead of a context switch and the finer the granularity of the threading system, the better will be the overall system utilization and its efficiency. For today's architectures we already see a flurry of libraries providing exactly this type of functionality: non-pre-emptive, task-queue based parallelization solutions, such as Intel Threading Building Blocks (TBB)<sup>166</sup>, Microsoft Parallel Patterns Library (PPL)<sup>167</sup>, Cilk++<sup>168</sup>, and many others. The possibility to suspend a current task if some preconditions for its execution are not met (such as waiting for I/O or the result of a different task), seamlessly switching to any other task which can continue, and to reschedule the initial task after the required result has been calculated, which makes the implementation of latency hiding almost trivial.

### Rediscover constraint-based synchronization to replace global barriers

The code we write today is riddled with implicit (and explicit) global barriers. By “global barriers,” we mean the synchronization of the control flow between several (very often all) threads (when using OpenMP<sup>169</sup>) or processes (MPI<sup>170</sup>). For instance, an implicit global barrier is inserted after each loop parallelized using OpenMP<sup>171</sup> as the system synchronizes the threads used to execute the different iterations in parallel. In MPI<sup>172</sup> each of the communication steps imposes an explicit barrier onto the execution flow as (often all) nodes have to be synchronized. Each of those barriers

<sup>162</sup> <http://en.wikipedia.org/wiki/InfiniBand>

<sup>163</sup> [https://en.wikipedia.org/wiki/Message\\_Passing\\_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

<sup>164</sup> <http://en.wikipedia.org/wiki/GPGPU>

<sup>165</sup> [http://en.wikipedia.org/wiki/Cray\\_XMT](http://en.wikipedia.org/wiki/Cray_XMT)

<sup>166</sup> <https://www.threadingbuildingblocks.org/>

<sup>167</sup> <https://msdn.microsoft.com/en-us/library/dd492418.aspx>

<sup>168</sup> <https://software.intel.com/en-us/articles/intel-cilk-plus/>

<sup>169</sup> <https://openmp.org/wp/>

<sup>170</sup> [https://en.wikipedia.org/wiki/Message\\_Passing\\_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

<sup>171</sup> <https://openmp.org/wp/>

<sup>172</sup> [https://en.wikipedia.org/wiki/Message\\_Passing\\_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

is like the eye of a needle the overall execution is forced to be squeezed through. Even minimal fluctuations in the execution times of the parallel threads (jobs) causes them to wait. Additionally, it is often only one of the executing threads that performs the actual reduce operation, which further impedes parallelism. A closer analysis of a couple of key algorithms used in science applications reveals that these global barriers are not always necessary. In many cases it is sufficient to synchronize a small subset of the threads. Any operation should proceed whenever the preconditions for its execution are met, and only those. Usually there is no need to wait for iterations of a loop to finish before you can continue calculating other things; all you need is to complete the iterations that produce the required results for the next operation. Good bye global barriers, hello constraint based synchronization! People have been trying to build this type of computing (and even computers) since the 1970s. The theory behind what they did is based on ideas around static and dynamic dataflow. There are certain attempts today to get back to those ideas and to incorporate them with modern architectures. For instance, a lot of work is being done in the area of constructing dataflow-oriented execution trees. Our results show that employing dataflow techniques in combination with the other ideas, as outlined herein, considerably improves scalability for many problems.

### Adaptive locality control instead of static data distribution

While this principle seems to be a given for single desktop or laptop computers (the operating system is your friend), it is everything but ubiquitous on modern supercomputers, which are usually built from a large number of separate nodes (i.e., Beowulf clusters), tightly interconnected by a high-bandwidth, low-latency network. Today's prevalent programming model for those is MPI, which does not directly help with proper data distribution, leaving it to the programmer to decompose the data to all of the nodes the application is running on. There are a couple of specialized languages and programming environments based on PGAS<sup>173</sup> (Partitioned Global Address Space) designed to overcome this limitation, such as Chapel<sup>174</sup>, X10<sup>175</sup>, UPC<sup>176</sup>, or Fortress<sup>177</sup>. However, all systems based on PGAS rely on static data distribution. This works fine as long as this static data distribution does not result in heterogeneous workload distributions or other resource utilization imbalances. In a distributed system these imbalances can be mitigated by migrating part of the application data to different localities (nodes). The only framework supporting (limited) migration today is Charm++<sup>178</sup>. The first attempts towards solving related problem go back decades as well, a good example is the Linda coordination language<sup>179</sup>. Nevertheless, none of the other mentioned systems support data migration today, which forces the users to either rely on static data distribution and live with the related performance hits or to implement everything themselves, which is very tedious and difficult. We believe that the only viable way to flexibly support dynamic and adaptive *locality* control is to provide a global, uniform address space to the applications, even on distributed systems.

### Prefer moving work to the data over moving data to the work

For the best performance it seems obvious to minimize the amount of bytes transferred from one part of the system to another. This is true on all levels. At the lowest level we try to take advantage of processor memory caches, thus, minimizing memory latencies. Similarly, we try to amortize the data transfer time to and from GPGPUs<sup>180</sup> as much as possible. At high levels we try to minimize data transfer between different nodes of a cluster or between different virtual machines on the cloud. Our experience (well, it's almost common wisdom) shows that the amount of bytes necessary to encode a certain operation is very often much smaller than the amount of bytes encoding the data the operation is performed upon. Nevertheless, we still often transfer the data to a particular place where we execute the operation just to bring the data back to where it came from afterwards. As an example let's look at the way we usually write our applications for clusters using MPI. This programming model is all about data transfer between nodes. MPI is the prevalent programming model for clusters, and it is fairly straightforward to understand and to use. Therefore,

<sup>173</sup> <https://www.pgas.org/>

<sup>174</sup> <https://chapel.cray.com/>

<sup>180</sup> <http://en.wikipedia.org/wiki/GPGPU>

we often write applications in a way that accommodates this model, centered around data transfer. These applications usually work well for smaller problem sizes and for regular data structures. The larger the amount of data we have to churn and the more irregular the problem domain becomes, the worse the overall machine utilization and the (strong) scaling characteristics become. While it is not impossible to implement more dynamic, data driven, and asynchronous applications using MPI, it is somewhat difficult to do so. At the same time, if we look at applications that prefer to execute the code close to the *locality* where the data was placed, i.e., utilizing active messages (for instance based on Charm++<sup>181</sup>), we see better asynchrony, simpler application codes, and improved scaling.

### Favor message driven computation over message passing

Today's prevalently used programming model on parallel (multi-node) systems is MPI. It is based on message passing, as the name implies, which means that the receiver has to be aware of a message about to come in. Both codes, the sender and the receiver, have to synchronize in order to perform the communication step. Even the newer, asynchronous interfaces require explicitly coding the algorithms around the required communication scheme. As a result, everything but the most trivial MPI applications spends a considerable amount of time waiting for incoming messages, thus, causing starvation and latencies to impede full resource utilization. The more complex and more dynamic the data structures and algorithms become, the larger the adverse effects. The community discovered message-driven and data-driven methods of implementing algorithms a long time ago, and systems such as Charm++<sup>182</sup> have already integrated active messages demonstrating the validity of the concept. Message-driven computation allows for sending messages without requiring the receiver to actively wait for them. Any incoming message is handled asynchronously and triggers the encoded action by passing along arguments and—possibly—continuations. HPX combines this scheme with work-queue based scheduling as described above, which allows the system to almost completely overlap any communication with useful work, thereby minimizing latencies.

## 2.7 Overview

HPX is organized into different sub-libraries and those in turn into modules. The libraries and modules are independent, with clear dependencies and no cycles. As an end-user, the use of these libraries is completely transparent. If you use e.g. `add_hpx_executable` to create a target in your project you will automatically get all modules as dependencies. See below for a list of the available libraries and modules. Currently these are nothing more than an internal grouping and do not affect usage. They cannot be consumed individually at the moment.

---

**Note:** There is a dependency report that displays useful information about the structure of the code. It is available for each commit at [HPX Dependency report](#).

---

### 2.7.1 Core modules

#### affinity

The affinity module contains helper functionality for mapping worker threads to hardware resources.

See the API reference of the module for more details.

#### algorithms

The algorithms module exposes the full set of algorithms defined by the C++ standard. There is also partial support for C++ ranges.

See the [API reference](#) of the module for more details.

#### allocator\_support

This module provides utilities for allocators. It contains `hpx::util::internal_allocator` which directly forwards allocation calls to `jemalloc`. This utility is mainly useful on Windows.

See the API reference of the module for more details.

#### asio

The asio module is a thin wrapper around the Boost.ASIO library, providing a few additional helper functions.

See the [API reference](#) of the module for more details.

#### assertion

The assertion library implements the macros `HPX_ASSERT` and `HPX_ASSERT_MSG`. Those two macros can be used to implement assertions which are turned off during a release build.

By default, the location and function where the assert has been called from are displayed when the assertion fires. This behavior can be modified by using `hpx::assertion::set_assertion_handler`. When HPX initializes, it uses this function to specify a more elaborate assertion handler. If your application needs to customize this, it needs to do so before calling `hpx::hpx_init`, `hpx::hpx_main` or using the C-main wrappers.

See the [API reference](#) of the module for more details.

## async\_base

The `async_base` module defines the basic functionality for spawning tasks on thread pools. This module does not implement any functionality on its own, but is extended by `async_local` and `modules_async_distributed` with implementations for the local and distributed cases.

See the [API reference](#) of this module for more details.

## async\_combinators

This module contains combinators for futures. The `when_*` functions allow you to turn multiple futures into a single future which is ready when all, any, some, or each of the given futures are ready. The `wait_*` combinators are equivalent to the `when_*` functions except that they do not return a future. Those wait for all futures to become ready before returning to the user. Note that the `wait_*` functions will rethrow one of the exceptions from exceptional futures. The `wait_*_nothrow` combinators are equivalent to the `wait_*` functions exception that they do not throw if one of the futures has become exceptional.

The `split_future` combinator takes a single future of a container (e.g. `tuple`) and turns it into a container of futures.

See `lcos_local`, `synchronization`, and `async` for other synchronization facilities.

See the [API reference](#) of this module for more details.

## async\_cuda

This library adds a simple API that enables the user to retrieve a future from a cuda stream. Typically, a user may launch one or more kernels and then get a future from the stream that will become ready when those kernels have completed. It is important to note that multiple kernels may be launched without fetching a future, and multiple futures may be obtained from the helper. Please refer to the unit tests and examples for further examples.

See the [API reference](#) of this module for more details.

## async\_local

This module extends `async_base` to provide local implementations of `hpx::async`, `hpx::apply`, `hpx::sync`, and `hpx::dataflow`.

See the API reference of this module for more details.

## async\_mpi

The MPI library is intended to simplify the process of integrating MPI based codes with the *HPX* runtime. Any MPI function that is asynchronous and uses an MPI\_Request may be converted into an `hpx::future`. The syntax is designed to allow a simple replacement of the MPI call with a futurized async version that accepts an executor instead of a communicator, and returns a future instead of assigning a request. Typically, an MPI call of the form

```
int MPI_Isend(buf, count, datatype, rank, tag, comm, request);
```

becomes

```
hpx::future<int> f = hpx::async(executor, MPI_Isend, buf, count, datatype, rank, tag);
```

When the MPI operation is complete, the future will become ready. This allows communication to integrated cleanly with the rest of HPX, in particular the continuation style of programming may be used to build up more complex code. Consider the following example, that chains user processing, sends and receives using continuations...

```

// create an executor for MPI dispatch
hpx::mpi::experimental::executor exec(MPI_COMM_WORLD);

// post an asynchronous receive using MPI_Irecv
hpx::future<int> f_recv = hpx::async(
    exec, MPI_Irecv, &data, rank, MPI_INT, rank_from, i);

// attach a continuation to run when the recv completes,
f_recv.then([=, &tokens, &counter](auto&&)
{
    // call an application specific function
    msg_recv(rank, size, rank_to, rank_from, tokens[i], i);

    // send a new message
    hpx::future<int> f_send = hpx::async(
        exec, MPI_Isend, &tokens[i], 1, MPI_INT, rank_to, i);

    // when that send completes
    f_send.then([=, &tokens, &counter](auto&&)
    {
        // call an application specific function
        msg_send(rank, size, rank_to, rank_from, tokens[i], i);
    });
}
}

```

The example above makes use of MPI\_Isend and MPI\_Irecv, but *any* MPI function that uses requests may be futurized in this manner. The following is a (non exhaustive) list of MPI functions that *should* be supported, though not all have been tested at the time of writing (please report any problems to the issue tracker).

```

int MPI_Isend(...);
int MPI_Ibsend(...);
int MPI_Issend(...);
int MPI_Irsend(...);
int MPI_Irecv(...);
int MPI_Imrecv(...);
int MPI_Ibarrier(...);
int MPI_Ibcast(...);
int MPI_Igather(...);
int MPI_Igatherv(...);
int MPI_Iscatter(...);
int MPI_Iscatterv(...);
int MPI_Iallgather(...);
int MPI_Iallgatherv(...);
int MPI_Ialltoall(...);
int MPI_Ialltoallv(...);
int MPI_Ialltoallw(...);
int MPI_Ireduce(...);
int MPI_Iallreduce(...);
int MPI_Ireduce_scatter(...);
int MPI_Ireduce_scatter_block(...);
int MPI_Iscan(...);
int MPI_Iexscan(...);
int MPI_Ineighbor_allgather(...);

```

(continues on next page)

(continued from previous page)

```
int MPI_Ineighbor_allgatherv(...);
int MPI_Ineighbor_alltoall(...);
int MPI_Ineighbor_alltoallv(...);
int MPI_Ineighbor_alltoallw(...);
```

Note that the *HPX* mpi futurization wrapper should work with *any* asynchronous *MPI* call, as long as the function signature has the last two arguments *MPI\_xxx(..., MPI\_Comm comm, MPI\_Request \*request)* - internally these two parameters will be substituted by the executor and future data parameters that are supplied by template instantiations inside the *hpx::mpi* code.

See the API reference of this module for more details.

## batch\_environments

This module allows for the detection of execution as batch jobs, a series of programs executed without user intervention. All data is preselected and will be executed according to preset parameters, such as date or completion of another task. Batch environments are especially useful for executing repetitive tasks.

*HPX* supports the creation of batch jobs through the Portable Batch System (PBS) and SLURM.

For more information on batch environments, see [Running on batch systems](#) and the API reference for the module.

## cache

This module provides two cache data structures:

- *hpx::util::cache::local\_cache*
- *hpx::util::cache::lru\_cache*

See the [API reference](#) of the module for more details.

## command\_line\_handling\_local

TODO: High-level description of the module.

See the API reference of this module for more details.

## compute\_local

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## concepts

This module provides helpers for emulating concepts. It provides the following macros:

- `HPX_CONCEPT_REQUIRES`
- `HPX_HAS_MEMBER_XXX_TRAIT_DEF`
- `HPX_HAS_XXX_TRAIT_DEF`

See the API reference of the module for more details.

## concurrency

This module provides concurrency primitives useful for multi-threaded programming such as:

- `hpx::util::barrier`
- `hpx::util::cache_line_data` and `hpx::util::cache_aligned_data`: wrappers for aligning and padding data to cache lines.
- various lockfree queue data structures

See the API reference of the module for more details.

## config

The config module contains various configuration options, typically hidden behind macros that choose the correct implementation based on the compiler and other available options.

See the [API reference](#) of the module for more details.

## config\_registry

The config\_registry module is a low level module providing helper functionality for registering configuration entries to a global registry from other modules. The `hpx::config_registry::add_module_config` function is used to add configuration options, and `hpx::config_registry::get_module_configs` can be used to retrieve configuration entries registered so far. `add_module_config_helper` can be used to register configuration entries through static global options.

See the API reference of this module for more details.

## coroutines

The coroutines module provides coroutine (user-space thread) implementations for different platforms.

See the [API reference](#) of the module for more details.

## datastructures

The datastructures module provides basic data structures (typically provided for compatibility with older C++ standards):

- `hpx::detail::small_vector`
- `hpx::util::basic_any`
- `hpx::util::member_pack`
- `hpx::optional`
- `hpx::util::tuple`
- `hpx::variant`

See the API reference of the module for more details.

## debugging

This module provides helpers for demangling symbol names.

See the [API reference](#) of the module for more details.

## errors

This module provides support for exceptions and error codes:

- `hpx::exception`
- `hpx::error_code`
- `hpx::error`

See the [API reference](#) of the module for more details.

## execution

This library implements executors and execution policies for use with parallel algorithms and other facilities related to managing the execution of tasks.

See the [API reference](#) of the module for more details.

## execution\_base

The basic execution module is the main entry point to implement parallel and concurrent operations. It is modeled after P0443<sup>190</sup> with some additions and implementations for the described concepts. Most notably, it provides an abstraction for execution resources, execution contexts and execution agents in such a way, that it provides customization points that those aforementioned concepts can be replaced and combined with ease.

For that purpose, three virtual base classes are provided to be able to provide implementations with different properties:

- **resource\_base:** This is the abstraction for execution resources, that is for example CPU cores or an accelerator.
- **context\_base:** An execution context uses execution resources and is able to spawn new execution agents, as new threads of executions on the available resources.

---

<sup>190</sup> <http://wg21.link/p0443>

- **agent\_base**: The execution agent represents the thread of execution, and can be used to yield, suspend, resume or abort a thread of execution.

## executors

The executors module exposes executors and execution policies. Most importantly, it exposes the following classes and constants:

- `hpx::execution::sequenced_executor`
- `hpx::execution::parallel_executor`
- `hpx::execution::sequenced_policy`
- `hpx::execution::parallel_policy`
- `hpx::execution::parallel_unsequenced_policy`
- `hpx::execution::sequenced_task_policy`
- `hpx::execution::parallel_task_policy`
- `hpx::execution::seq`
- `hpx::execution::par`
- `hpx::execution::par_unseq`
- `hpx::execution::task`

See the [API reference](#) of this module for more details.

## filesystem

This module provides a compatibility layer for the C++17 filesystem library. If the filesystem library is available this module will simply forward its contents into the `hpx::filesystem` namespace. If the library is not available it will fall back to Boost.Filesystem instead.

See the [API reference](#) of the module for more details.

## format

The format module exposes the `format` and `format_to` functions for formatting strings.

See the API reference of the module for more details.

## functional

This module provides function wrappers and helpers for managing functions and their arguments.

- `hpx::function`
- `hpx::function_ref_`
- `hpx::move_only_function`
- `hpx::bind`
- `hpx::bind_back`
- `hpx::bind_front`

- `hpx::util::deferred_call`
- `hpx::util::invoke`
- `hpx::util::invoke_fused`
- `hpx::util::mem_fn`
- `hpx::util::one_shot`
- `hpx::util::protect`
- `hpx::util::result_of`
- `hpx::placeholders::_1`
- `hpx::placeholders::_2`
- ...
- `hpx::placeholders::_9`

See the [API reference](#) of the module for more details.

## futures

This module defines the `hpx::future` and `hpx::shared_future` classes corresponding to the C++ standard library classes `std::future` and `std::shared_future`. Note that the specializations of `hpx::future::then` for executors and execution policies are defined in the [execution](#) module.

See the [API reference](#) of this module for more details.

## hardware

The hardware module abstracts away hardware specific details of timestamps and CPU features.

See the API reference of the module for more details.

## hashing

The hashing module provides two hashing implementations:

- `hpx::util::fibhash`
- `hpx::util::jenkins_hash`

See the API reference of the module for more details.

## include\_local

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together. This module provides local-only headers.

See the API reference of this module for more details.

## ini

TODO: High-level description of the module.

See the API reference of this module for more details.

## init\_runtime\_local

TODO: High-level description of the module.

See the API reference of this module for more details.

## io\_service

This module provides an abstraction over Boost.ASIO, combining multiple `asio::io_contexts` into a single pool. `hpx::util::io_service_pool` provides a simple pool of `asio::io_contexts` with an API similar to `asio::io_context`. `hpx::threads::detail::io_service_thread_pool` wraps `hpx::util::io_service_pool` into an interface derived from `hpx::threads::detail::thread_pool_base`.

See the [API reference](#) of this module for more details.

## iterator\_support

This module provides helpers for iterators. It provides `hpx::util::iterator_facade` and `hpx::util::iterator_adaptor` for creating new iterators, and the trait `hpx::util::is_iterator` along with more specific iterator traits.

See the API reference of the module for more details.

## itt\_notify

This module provides support for profiling with Intel VTune<sup>191</sup>.

See the API reference of this module for more details.

## lci\_base

This module provides helper functionality for detecting MPI environments.

See the API reference of this module for more details.

## lcos\_local

This module provides the following local *LCOs*:

- `hpx::lcos::local::and_gate`
- `hpx::lcos::local::channel`
- `hpx::lcos::local::one_element_channel`
- `hpx::lcos::local::receive_channel`
- `hpx::lcos::local::send_channel`

---

<sup>191</sup> <https://software.intel.com/content/www/us/en/develop/tools/vtune-profiler.html>

- `hpx::lcos::local::guard`
- `hpx::lcos::local::guard_set`
- `hpx::lcos::local::run_guarded`
- `hpx::lcos::local::conditional_trigger`
- `hpx::packaged_task`
- `hpx::promise`
- `hpx::lcos::local::receive_buffer`
- `hpx::lcos::local::trigger`

See `lcos_distributed` for distributed LCOs. Basic synchronization primitives for use in HPX threads can be found in `synchronization`. `async_combinators` contains useful utility functions for combining futures.

See the [API reference](#) of this module for more details.

## lock\_registration

This module contains functionality for registering locks to detect when they are locked and unlocked on different threads.

See the API reference of this module for more details.

## logging

This module provides useful macros for logging information.

See the API reference of the module for more details.

## memory

Part of this module is a forked version of `boost::intrusive_ptr` from `Boost.SmartPtr`.

See the API reference of the module for more details.

## mpi\_base

This module provides helper functionality for detecting MPI environments.

See the API reference of this module for more details.

## pack\_traversal

This module exposes the basic functionality for traversing various packs, both synchronously and asynchronously: `hpx::util::traverse_pack` and `hpx::util::traverse_pack_async`. It also exposes the higher level functionality of unwrapping nested futures: `hpx::util::unwrap` and its function object form `hpx::util::functional::unwrap`.

See the [API reference](#) of this module for more details.

## plugin

This module provides base utilities for creating plugins.

See the API reference of the module for more details.

## prefix

This module provides utilities for handling the prefix of an *HPX* application, i.e. the paths used for searching components and plugins.

See the API reference of this module for more details.

## preprocessor

This library contains useful preprocessor macros:

- *HPX\_PP\_CAT*
- *HPX\_PP\_EXPAND*
- *HPX\_PP\_NARGS*
- *HPX\_PP\_STRINGIZE*
- *HPX\_PP\_STRIP\_PARENS*

See the *API reference* of the module for more details.

## program\_options

The module `program_options` is a direct fork of the Boost.ProgramOptions library (Boost V1.70.0). For more information about this library please see [here<sup>192</sup>](#). In order to be included as an *HPX* module, the Boost.ProgramOptions library has been moved to the namespace `hpx::program_options`. We have also replaced all Boost facilities the library depends on with either the equivalent facilities from the standard library or from *HPX*. As a result, the *HPX* `program_options` module is fully interface compatible with Boost.ProgramOptions (sans the `hpx` namespace and the `#include <hpx/modules/program_options.hpp>` changes that need to be applied to all code relying on this library).

All credit goes to Vladimir Prus, the author of the excellent Boost.ProgramOptions library. All bugs have been introduced by us.

See the API reference of the module for more details.

## properties

This module implements the `prefer` customization point for properties in terms of [P2220<sup>193</sup>](#). This differs from [P1393<sup>194</sup>](#) in that it relies fully on `tag_invoke` overloads and fewer base customization points. Actual properties are defined in modules. All functionality is experimental and can be accessed through the `hpx::experimental` namespace.

See the API reference of this module for more details.

<sup>194</sup> [http://wg21.link/p1393](https://wg21.link/p1393)

## resiliency

In *HPX*, a program failure is a manifestation of a failing task. This module exposes several APIs that allow users to manage failing tasks in a convenient way by either replaying a failed task or by replicating a specific task.

Task replay is analogous to the Checkpoint/Restart mechanism found in conventional execution models. The key difference being localized fault detection. When the runtime detects an error, it replays the failing task as opposed to completely rolling back the entire program to the previous checkpoint.

Task replication is designed to provide reliability enhancements by replicating a set of tasks and evaluating their results to determine a consensus among them. This technique is most effective in situations where there are few tasks in the critical path of the DAG which leaves the system underutilized or where hardware or software failures may result in an incorrect result instead of an error. However, the drawback of this method is the additional computational cost incurred by repeating a task multiple times.

The following API functions are exposed:

- `hpx::resiliency::experimental::async_replay`: This version of task replay will catch user-defined exceptions and automatically reschedule the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception.
- `hpx::resiliency::experimental::async_replay_validate`: This version of replay adds an argument to async replay which receives a user-provided validation function to test the result of the task against. If the task's output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries has been exceeded.
- `hpx::resiliency::experimental::async_replicate`: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors.
- `hpx::resiliency::experimental::async_replicate_validate`: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned.
- `hpx::resiliency::experimental::async_replicate_vote`: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer.
- `hpx::resiliency::experimental::async_replicate_vote_validate`: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic.
- `hpx::resiliency::experimental::dataflow_replay`: This version of dataflow replay will catch user-defined exceptions and automatically reschedules the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- `hpx::resiliency::experimental::dataflow_replay_validate`: This version of replay adds an argument to dataflow replay which receives a user-provided validation function to test the result of the task against. If the task's output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries have been exceeded. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

- `hpx::resiliency::experimental::dataflow_replicate`: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- `hpx::resiliency::experimental::dataflow_replicate_validate`: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- `hpx::resiliency::experimental::dataflow_replicate_vote`: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- `hpx::resiliency::experimental::dataflow_replicate_vote_validate`: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

See the [API reference](#) of the module for more details.

### **resource\_partitioner**

The resource\_partitioner module defines `hpx::resource::partitioner`, the class used by the runtime and users to partition available hardware resources into thread pools. See [Using the resource partitioner](#) for more details on using the resource partitioner in applications.

See the API reference of this module for more details.

### **runtimme\_configuration**

This module handles the configuration options required by the runtime.

See the [API reference](#) of this module for more details.

### **runtimme\_local**

TODO: High-level description of the library.

See the [API reference](#) of this module for more details.

## schedulers

This module provides schedulers used by thread pools in the [thread\\_pools](#) module. There are currently three main schedulers:

- `hpx::threads::local_priority_queue_scheduler`
- `hpx::threads::static_priority_queue_scheduler`
- `hpx::threads::shared_priority_queue_scheduler`

Other schedulers are specializations or variations of the above schedulers. See the examples of the [resource\\_partitioner](#) module for examples of specifying a custom scheduler for a thread pool.

See the API reference of this module for more details.

## serialization

This module provides serialization primitives and support for all built-in types as well as all C++ Standard Library collection and utility types. This list is extended by *HPX* vocabulary types with proper support for global reference counting. *HPX*'s mode of serialization is derived from Boost's serialization model<sup>195</sup> and, as such, is mostly interface compatible with its Boost counterpart.

The purest form of serializing data is to copy the content of the payload bit by bit; however, this method is impractical for generic C++ types, which might be composed of more than just regular built-in types. Instead, *HPX*'s approach to serialization is derived from the Boost Serialization library, and is geared towards allowing the programmer of a given class explicit control and syntax of what to serialize. It is based on operator overloading of two special archive types that hold a buffer or stream to store the serialized data and is responsible for dispatching the serialization mechanism to the intrusive or non-intrusive version. The serialization process is recursive. Each member that needs to be serialized must be specified explicitly. The advantage of this approach is that the serialization code is written in C++ and leverages all necessary programming techniques. The generic, user-facing interface allows for effective application of the serialization process without obstructing the algorithms that need special code for packing and unpacking. It also allows for optimizations in the implementation of the archives.

See the [API reference](#) of the module for more details.

## static\_reinit

This module provides a simple wrapper around static variables that can be reinitialized.

See the [API reference](#) of this module for more details.

## string\_util

This module contains string utilities inspired by the Boost string algorithms library.

See the API reference of this module for more details.

---

<sup>195</sup> [https://www.boost.org/doc/libs/1\\_72\\_0/libs/serialization/doc/index.html](https://www.boost.org/doc/libs/1_72_0/libs/serialization/doc/index.html)

## synchronization

This module provides synchronization primitives that should be used rather than the C++ standard ones in *HPX* threads:

- `hpx::barrier`
- `hpx::binary_semaphore`
- `hpx::call_once`
- `hpx::condition_variable`
- `hpx::condition_variable_any`
- `hpx::counting_semaphore`
- `hpx::lcos::local::event`
- `hpx::latch`
- `hpx::mutex`
- `hpx::no_mutex`
- `hpx::once_flag`
- `hpx::recursive_mutex`
- `hpx::shared_mutex`
- `hpx::sliding_semaphore`
- `hpx::spinlock` (`std::mutex` compatible spinlock)
- `hpx::spinlock_no_backoff` (`boost::mutex` compatible spinlock)
- `hpx::spinlock_pool`
- `hpx::stop_callback`
- `hpx::stop_source`
- `hpx::stop_token`
- `hpx::in_place_stop_token`
- `hpx::timed_mutex`
- `hpx::upgrade_to_unique_lock`
- `hpx::upgrade_lock`

See `lcos_local`, `async_combinators`, and `async` for higher level synchronization facilities.

See the [API reference](#) of this module for more details.

## tag\_invoke

TODO: High-level description of the module.

See the API reference of this module for more details.

## testing

The testing module contains useful macros for testing. The results of tests can be printed with `hpx::util::report_errors`. The following macros are provided:

- `HPX_TEST`
- `HPX_TEST_MSG`
- `HPX_TEST_EQ`
- `HPX_TEST_NEQ`
- `HPX_TEST_LT`
- `HPX_TEST_LTE`
- `HPX_TEST_RANGE`
- `HPX_TEST_EQ_MSG`
- `HPX_TEST_NEQ_MSG`
- `HPX_SANITY`
- `HPX_SANITY_MSG`
- `HPX_SANITY_EQ`
- `HPX_SANITY_NEQ`
- `HPX_SANITY_LT`
- `HPX_SANITY_LTE`
- `HPX_SANITY_RANGE`
- `HPX_SANITY_EQ_MSG`

See the API reference of the module for more details.

## thread\_pool\_util

This module contains helper functions for asynchronously suspending and resuming thread pools and their worker threads.

See the [API reference](#) of this module for more details.

## thread\_pools

This module defines the thread pools and utilities used by the *HPX* runtime. The only thread pool implementation provided by this module is `hpx::threads::detail::scheduled_thread_pool`, which is derived from `hpx::threads::detail::thread_pool_base` defined in the [threading\\_base](#) module.

See the API reference of this module for more details.

## thread\_support

This module provides miscellaneous utilities for threading and concurrency.

See the API reference of the module for more details.

## threading

This module provides the equivalents of `std::thread` and `std::jthread` for lightweight *HPX* threads:

- `hpx::thread`
- `hpx::jthread`

See the API reference of this module for more details.

## threading\_base

This module contains the base class definition required for threads. The base class `hpx::threads::thread_data` is inherited by two specializations for stackful and stackless threads: `hpx::threads::thread_data_stackful` and `hpx::threads::thread_data_stackless`. In addition, the module defines the base classes for schedulers and thread pools: `hpx::threads::policies::scheduler_base` and `hpx::threads::thread_pool_base`.

See the API reference of this module for more details.

## thread\_manager

This module defines the `hpx::threads::threadmanager` class. This is used by the runtime to manage the creation and destruction of thread pools. The `resource_partitioner` module handles the partitioning of resources into thread pools, but not the creation of thread pools.

See the API reference of this module for more details.

## timed\_execution

This module provides extensions to the executor interfaces defined in the `execution` module that allow timed submission of tasks on thread pools (at or after a specified time).

See the `API reference` of this module for more details.

## timing

This module provides the timing utilities (clocks and timers).

See the API reference of the module for more details.

## topology

This module provides the class `hpx::threads::topology` which represents the hardware resources available on a node. The class is a light wrapper around the Portable Hardware Locality (HWLOC)<sup>196</sup> library. The `hpx::threads::cpu_mask` is a small companion class that represents a set of resources on a node.

See the [API reference](#) of the module for more details.

## type\_support

This module provides helper facilities related to types.

See the API reference of the module for more details.

## util

The util module provides miscellaneous standalone utilities.

See the [API reference](#) of the module for more details.

## version

This module macros and functions for accessing version information about *HPX* and its dependencies.

See the [API reference](#) of this module for more details.

## 2.7.2 Main HPX modules

### actions

TODO: High-level description of the library.

See the [API reference](#) of this module for more details.

### actions\_base

TODO: High-level description of the library.

See the [API reference](#) of this module for more details.

### agas

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

---

<sup>196</sup> <https://www.open-mpi.org/projects/hwloc/>

## agas\_base

This module holds the implementation of the four AGAS services: primary namespace, locality namespace, component namespace, and symbol namespace.

See the [API reference](#) of this module for more details.

## async\_colocated

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## async

This module contains functionality for asynchronously launching work on remote localities: `hpx::async`, `hpx::apply`. This module extends the local-only functions in `libs_async_local`.

See the API reference of this module for more details.

## checkpoint

A common need of users is to periodically backup an application. This practice provides resiliency and potential restart points in code. *HPX* utilizes the concept of a `checkpoint` to support this use case.

Found in `hpx/util/checkpoint.hpp`, `checkpoints` are defined as objects that hold a serialized version of an object or set of objects at a particular moment in time. This representation can be stored in memory for later use or it can be written to disk for storage and/or recovery at a later point. In order to create and fill this object with data, users must use a function called `save_checkpoint`. In code the function looks like this:

```
hpx::future<hpx::util::checkpoint> hpx::util::save_checkpoint(a, b, c, ...);
```

`save_checkpoint` takes arbitrary data containers, such as `int`, `double`, `float`, `vector`, and `future`, and serializes them into a newly created `checkpoint` object. This function returns a `future` to a `checkpoint` containing the data. Here's an example of a simple use case:

```
using hpx::util::checkpoint;
using hpx::util::save_checkpoint;

std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> save_checkpoint(vec);
```

Once the future is ready, the `checkpoint` object will contain the `vector` `vec` and its five elements.

`prepare_checkpoint` takes arbitrary data containers (same as for `save_checkpoint`), , such as `int`, `double`, `float`, `vector`, and `future`, and calculates the necessary buffer space for the `checkpoint` that would be created if `save_checkpoint` was called with the same arguments. This function returns a `future` to a `checkpoint` that is appropriately initialized. Here's an example of a simple use case:

```
using hpx::util::checkpoint;
using hpx::util::prepare_checkpoint;

std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> prepare_checkpoint(vec);
```

Once the future is ready, the checkpoint object will be initialized with an appropriately sized internal buffer.

It is also possible to modify the launch policy used by `save_checkpoint`. This is accomplished by passing a launch policy as the first argument. It is important to note that passing `hpx::launch::sync` will cause `save_checkpoint` to return a `checkpoint` instead of a `future` to a `checkpoint`. All other policies passed to `save_checkpoint` will return a `future` to a `checkpoint`.

Sometimes `checkpoint`s must be declared before they are used. `save_checkpoint` allows users to move pre-created `checkpoint`s into the function as long as they are the first container passing into the function (In the case where a launch policy is used, the `checkpoint` will immediately follow the launch policy). An example of these features can be found below:

```
char character = 'd';
int integer = 10;
float flt = 10.01f;
bool boolean = true;
std::string str = "I am a string of characters";
std::vector<char> vec(str.begin(), str.end());
checkpoint archive;

// Test 1
// test basic functionality
hpx::shared_future<checkpoint> f_archive = save_checkpoint(
    std::move(archive), character, integer, flt, boolean, str, vec);
```

Once users can create `checkpoints` they must now be able to restore the objects they contain into memory. This is accomplished by the function `restore_checkpoint`. This function takes a `checkpoint` and fills its data into the containers it is provided. It is important to remember that the containers must be ordered in the same way they were placed into the `checkpoint`. For clarity see the example below:

```
char character2;
int integer2;
float flt2;
bool boolean2;
std::string str2;
std::vector<char> vec2;

restore_checkpoint(data, character2, integer2, flt2, boolean2, str2, vec2);
```

The core utility of `checkpoint` is in its ability to make certain data persistent. Often, this means that the data needs to be stored in an object, such as a file, for later use. *HPX* has two solutions for these issues: stream operator overloads and access iterators.

*HPX* contains two stream overloads, `operator<<` and `operator>>`, to stream data out of and into `checkpoint`. Here is an example of the overloads in use below:

```
double a9 = 1.0, b9 = 1.1, c9 = 1.2;
std::ofstream test_file_9("test_file_9.txt");
hpx::future<checkpoint> f_9 = save_checkpoint(a9, b9, c9);
test_file_9 << f_9.get();
test_file_9.close();

double a9_1, b9_1, c9_1;
std::ifstream test_file_9_1("test_file_9.txt");
checkpoint archive9;
```

(continues on next page)

(continued from previous page)

```
test_file_9_1 >> archive9;
restore_checkpoint(archive9, a9_1, b9_1, c9_1);
```

This is the primary way to move data into and out of a `checkpoint`. It is important to note, however, that users should be cautious when using a stream operator to load data and another function to remove it (or vice versa). Both `operator<<` and `operator>>` rely on a `.write()` and a `.read()` function respectively. In order to know how much data to read from the `std::istream`, the `operator<<` will write the size of the `checkpoint` before writing the `checkpoint` data. Correspondingly, the `operator>>` will read the size of the stored data before reading the data into a new instance of `checkpoint`. As long as the user employs the `operator<<` and `operator>>` to stream the data, this detail can be ignored.

---

**Important:** Be careful when mixing `operator<<` and `operator>>` with other facilities to read and write to a `checkpoint`. `operator<<` writes an extra variable, and `operator>>` reads this variable back separately. Used together the user will not encounter any issues and can safely ignore this detail.

---

Users may also move the data into and out of a `checkpoint` using the exposed `.begin()` and `.end()` iterators. An example of this use case is illustrated below.

```
std::ofstream test_file_7("checkpoint_test_file.txt");
std::vector<float> vec7{1.02f, 1.03f, 1.04f, 1.05f};
hpx::future<checkpoint> fut_7 = save_checkpoint(vec7);
checkpoint archive7 = fut_7.get();
std::copy(archive7.begin(),      // Write data to ostream
          archive7.end(),       // ie. the file
          std::ostream_iterator<char>(test_file_7));
test_file_7.close();

std::vector<float> vec7_1;
std::vector<char> char_vec;
std::ifstream test_file_7_1("checkpoint_test_file.txt");
if (test_file_7_1)
{
    test_file_7_1.seekg(0, test_file_7_1.end);
    auto length = test_file_7_1.tellg();
    test_file_7_1.seekg(0, test_file_7_1.beg);
    char_vec.resize(length);
    test_file_7_1.read(char_vec.data(), length);
}
checkpoint archive7_1(std::move(char_vec));    // Write data to checkpoint
restore_checkpoint(archive7_1, vec7_1);
```

## Checkpointing components

`save_checkpoint` and `restore_checkpoint` are also able to store components inside checkpoints. This can be done in one of two ways. First a client of the component can be passed to `save_checkpoint`. When the user wishes to resurrect the component she can pass a client instance to `restore_checkpoint`.

This technique is demonstrated below:

```
// Try to checkpoint and restore a component with a client
std::vector<int> vec3{10, 10, 10, 10, 10};

// Create a component instance through client constructor
data_client D(hpx::find_here(), std::move(vec3));
hpx::future<checkpoint> f3 = save_checkpoint(D);

// Create a new client
data_client E;

// Restore server inside client instance
restore_checkpoint(f3.get(), E);
```

The second way a user can save a component is by passing a `shared_ptr` to the component to `save_checkpoint`. This component can be resurrected by creating a new instance of the component type and passing a `shared_ptr` to the new instance to `restore_checkpoint`.

This technique is demonstrated below:

```
// test checkpoint a component using a shared_ptr
std::vector<int> vec{1, 2, 3, 4, 5};
data_client A(hpx::find_here(), std::move(vec));

// Checkpoint Server
hpx::id_type old_id = A.get_id();

hpx::future<std::shared_ptr<data_server>> f_a_ptr =
    hpx::get_ptr<data_server>(A.get_id());
std::shared_ptr<data_server> a_ptr = f_a_ptr.get();
hpx::future<checkpoint> f = save_checkpoint(a_ptr);
auto&& data = f.get();

// test prepare_checkpoint API
checkpoint c = prepare_checkpoint(hpx::launch::sync, a_ptr);
HPX_TEST(c.size() == data.size());

// Restore Server
// Create a new server instance
std::shared_ptr<data_server> b_server;
restore_checkpoint(data, b_server);
```

## checkpoint\_base

The checkpoint\_base module contains lower level facilities that wrap simple check-pointing capabilities. This module does not implement special handling for futures or components, but simply serializes all arguments to or from a given container.

This module exposes the `hpx::util::save_checkpoint_data`, `hpx::util::restore_checkpoint_data`, and `hpx::util::prepare_checkpoint_data` APIs. These functions encapsulate the basic serialization functionalities necessary to save/restore a variadic list of arguments to/from a given data container.

See the [API reference](#) of this module for more details.

## collectives

The collectives module exposes a set of distributed collective operations. Those can be used to exchange data between participating sites in a coordinated way. At this point the module exposes the following collective primitives:

- `hpx::collectives::all_gather`: receives a set of values from all participating sites.
- `hpx::collectives::all_reduce`: performs a reduction on data from each participating site to each participating site.
- `hpx::collectives::all_to_all`: each participating site provides its element of the data to collect while all participating sites receive the data from every other site.
- `hpx::collectives::broadcast_to` and `hpx::collectives::broadcast_from`: performs a broadcast operation from a root site to all participating sites.
- `cpp:func:hpx::collectives::exclusive_scan` performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.
- `hpx::collectives::gather_here` and `hpx::collectives::gather_there`: gathers values from all participating sites.
- `cpp:func:hpx::collectives::inclusive_scan` performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.
- `hpx::collectives::reduce_here` and `hpx::collectives::reduce_there`: performs a reduction on data from each participating site to a root site.
- `hpx::collectives::scatter_to` and `hpx::collectives::scatter_from`: receives an element of a set of values operating on the given base name.
- `hpx::lcos::broadcast`: performs a given action on all given global identifiers.
- `hpx::distributed::barrier`: distributed barrier.
- `hpx::lcos::fold`: performs a fold with a given action on all given global identifiers.
- `hpx::distributed::latch`: distributed latch.
- `hpx::lcos::reduce`: performs a reduction on data from each given global identifiers.
- `hpx::lcos::spmd_block`: performs the same operation on a local image while providing handles to the other images.

See the [API reference](#) of the module for more details.

## **command\_line\_handling**

The command\_line\_handling module defines and handles the command-line options required by the *HPX* runtime, combining them with configuration options defined by the *runtime\_configuration* module. The actual parsing of command line options is handled by the *program\_options* module.

See the API reference of the module for more details.

## **components**

TODO: High-level description of the module.

See the *API reference* of this module for more details.

## **components\_base**

TODO: High-level description of the library.

See the *API reference* of this module for more details.

## **compute**

The compute module provides utilities for handling task and memory affinity on host systems.

See the *API reference* of the module for more details.

## **distribution\_policies**

TODO: High-level description of the module.

See the *API reference* of this module for more details.

## **executors\_distributed**

This module provides the executor `hpx::parallel::execution::distribution_policy_executor`. It allows one to create work that is implicitly distributed over multiple localities.

See the *API reference* of this module for more details.

## **include**

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together.

See the API reference of this module for more details.

## **init\_runtime**

TODO: High-level description of the library.

See the [API reference](#) of this module for more details.

## **lcos\_distributed**

This module contains distributed *LCOs*. Currently the only LCO provided is :cpp:class:`hpx::lcos::channel`, a construct for sending values from one *locality* to another. See `libs_lcos_local` for local LCOs.

See the API reference of this module for more details.

## **naming**

TODO: High-level description of the module.

See the API reference of this module for more details.

## **naming\_base**

This module provides a forward declaration of *address\_type*, *component\_type* and *invalid\_locality\_id*.

See the [API reference](#) of this module for more details.

## **parcelport\_lci**

TODO: High-level description of the module.

See the API reference of this module for more details.

## **parcelport\_libfabric**

TODO: High-level description of the module.

See the API reference of this module for more details.

## **parcelport\_mpi**

TODO: High-level description of the module.

See the API reference of this module for more details.

## **parcelport\_tcp**

TODO: High-level description of the module.

See the API reference of this module for more details.

## parcelset

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## parcelset\_base

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## performance\_counters

This module provides the basic functionality required for defining performance counters. See [Performance counters](#) for more information about performance counters.

See the [API reference](#) of this module for more details.

## plugin\_factories

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## resiliency\_distributed

Software resiliency features of HPX were introduced in the [resiliency module](#). This module extends the APIs to run on distributed-memory systems allowing the user to invoke the failing task on other localities at runtime. This is useful in cases where a node is identified to fail more often (e.g., for certain ALU computes) as the task can now be replayed or replicated among different localities. The API exposed allows for an easy integration with the local only resiliency APIs as well.

Distributed software resilience APIs have a similar function signature and lives under the same namespace of `hpx::resiliency::experimental`. The difference arises in the formal parameters where distributed APIs takes the localities as the first argument, and an action as opposed to a function or a function object. The localities signify the order in which the API will either schedule (in case of Task Replay) tasks in a round robin fashion or replicate the tasks onto the list of localities.

The list of APIs exposed by distributed resiliency modules is the same as those defined in [local resiliency module](#).

See the API reference of this module for more details.

## runtime\_components

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## runtime\_distributed

TODO: High-level description of the module.

See the [API reference](#) of this module for more details.

## segmented\_algorithms

Segmented algorithms extend the usual parallel *algorithms* by providing overloads that work with distributed containers, such as partitioned vectors.

See the [API reference](#) of the module for more details.

## statistics

This module provide some statistics utilities like rolling min/max and histogram.

See the API reference of the module for more details.

## 2.8 API reference

HPX follows a versioning scheme with three numbers: `major.minor.patch`. We guarantee no breaking changes in the API for patch releases. Minor releases may remove or break existing APIs, but only after a deprecation period of at least two minor releases. In rare cases do we outright remove old and unused functionality without a deprecation period.

We do not provide any ABI compatibility guarantees between any versions, debug and release builds, and builds with different C++ standards.

The public API of HPX is presented below. Clicking on a name brings you to the full documentation for the class or function. Including the header specified in a heading brings in the features listed under that heading.

---

**Note:** Names listed here are guaranteed stable with respect to semantic versioning. However, at the moment the list is incomplete and certain unlisted features are intended to be in the public API. While we work on completing the list, if you're unsure about whether a particular unlisted name is part of the public API you can get into contact with us or open an issue and we'll clarify the situation.

---

### 2.8.1 Public API

Our API is semantically conforming; hence, the reader is highly encouraged to refer to the corresponding facility in the [C++ Standard](#)<sup>197</sup> if needed. All names below are also available in the top-level `hpx` namespace unless otherwise noted. The names in `hpx` should be preferred. The names in sub-namespaces will eventually be removed.

---

<sup>197</sup> <https://en.cppreference.com/w/cpp/header>

## hpx/algorithm.hpp

The header `hpx/algorithm.hpp`<sup>198</sup> corresponds to the C++ standard library header `algorithm`<sup>199</sup>. See [Using parallel algorithms](#) for more information about the parallel algorithms.

### Classes

Table 2.35: Classes of header `hpx/algorithm.hpp`

Class	C++ standard
<code>hpx::experimental::reduction</code>	N4808 <sup>200</sup>
<code>hpx::experimental::induction</code>	N4808 <sup>201</sup>

### Functions

## hpx/any.hpp

The header `hpx/any.hpp`<sup>329</sup> corresponds to the C++ standard library header `any`<sup>330</sup>.

`hpx::any` is compatible with `std::any`.

### Classes

Table 2.38: Classes of header `hpx/any.hpp`

Class	C++ standard
<code>hpx::any</code>	<code>std::any</code> <sup>331</sup>
<code>hpx::any_nons</code>	
<code>hpx::bad_any_cast</code>	<code>std::bad_any_cast</code> <sup>332</sup>
<code>hpx::unique_any_nons</code>	

### Functions

Table 2.39: Functions of header `hpx/any.hpp`

Function	C++ standard
<code>hpx::any_cast</code>	<code>std::any_cast</code> <sup>333</sup>
<code>hpx::make_any</code>	<code>std::make_any</code> <sup>334</sup>
<code>hpx::make_any_nons</code>	
<code>hpx::make_unique_any_nons</code>	

## hpx/assert.hpp

The header `hpx/assert.hpp`<sup>335</sup> corresponds to the C++ standard library header `cassert`<sup>336</sup>.

`HPX_ASSERT` is the *HPX* equivalent to `assert` in `cassert`. `HPX_ASSERT` can also be used in CUDA device code.

### Macros

Table 2.40: Macros of header `hpx/assert.hpp`

Macro
<code>HPX_ASSERT</code>

p.set_value(123.45);
HPX_ASSERT(f4.is_ready());

hpx::packaged_task<int()> t([]() { return 43; });
hpx::future<int> f5 = t.get_future();
HPX_ASSERT(!f5.is_ready());
t();
HPX_ASSERT(f5.is_ready());

// Fire-and-forget
hpx::apply([]() {
    std::cout << "This will be printed later\n" << std::flush;
});

// Synchronous execution
hpx::sync([]() {
    std::cout << "This will be printed immediately\n" << std::flush;
});

// Combinators
hpx::future<double> f6 = hpx::async([]() { return 3.14; });
hpx::future<double> f7 = hpx::async([]() { return 42.0; });
std::cout
    << hpx::when_all(f6, f7)
        .then([](hpx::future<
            hpx::tuple<hpx::future<double>, hpx::future<double>>>
            f) {
            hpx::tuple<hpx::future<double>, hpx::future<double>> t =
                f.get();
            double pi = hpx::get<0>(t).get();
            double r = hpx::get<1>(t).get();
            return pi * r * r;
        })
        .get()
    << std::endl;

// Easier continuations with dataflow; it waits for all future or
// shared_future arguments before executing the continuation, and also
// accepts non-future arguments
hpx::future<double> f8 = hpx::async([]() { return 3.14; });
hpx::future<double> f9 = hpx::make_ready_future(42.0);
hpx::shared_future<double> f10 = hpx::async([]() { return 123.45; });
hpx::future<hpx::tuple<double, double>> f11 = hpx::dataflow(

```

(continues on next page)

(continued from previous page)

```

[] (hpx::future<double> a, hpx::future<double> b,
    hpx::shared_future<double> c, double d) {
    return hpx::make_tuple<>(a.get() + b.get(), c.get() / d);
},
f8, f9, f10, -3.9);

// split_future gives a tuple of futures from a future of tuple
hpx::tuple<hpx::future<double>, hpx::future<double>> f12 =
    hpx::split_future(std::move(f11));
std::cout << hpx::get<1>(f12).get() << std::endl;

return 0;
}

```

## hpx/init.hpp

The header `hpx/init.hpp`<sup>380</sup> contains functionality for starting, stopping, suspending, and resuming the *HPX* runtime. This is the main way to explicitly start the *HPX* runtime. See [Starting the HPX runtime](#) for more details on starting the *HPX* runtime.

### Classes

Table 2.56: Classes of header `hpx/init.hpp`

<code>hpx::ranges::transform_inclusive_scan</code>

## hpx/optional.hpp

The header `hpx/optional.hpp`<sup>423</sup> corresponds to the C++ standard library header `optional`<sup>424</sup>. `hpx::optional` is compatible with `std::optional`.

### Constants

- `hpx::nullopt`

### Classes

Table 2.66: Classes of header `hpx/optional.hpp`

Class	C++ standard
<code>hpx::optional</code>	<code>std::optional</code> <sup>425</sup>
<code>hpx::nullopt_t</code>	<code>std::nullopt_t</code> <sup>426</sup>
<code>hpx::bad_optional_access</code>	<code>std::bad_optional_access</code> <sup>427</sup>

## hpx/runtime.hpp

The header `hpx/runtime.hpp`<sup>428</sup> contains functions for accessing local and distributed runtime information.

### Typedefs

Table 2.67: Typedefs of header `hpx/runtime.hpp`

Typedef
<code>hpx::startup_function_type</code>
<code>hpx::shutdown_function_type</code>

<sup>423</sup> <http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/optional.hpp>

<sup>424</sup> <http://en.cppreference.com/w/cpp/header/optional>

<sup>425</sup> <http://en.cppreference.com/w/cpp/utility/optional>

<sup>426</sup> [http://en.cppreference.com/w/cpp/utility/nullopt\\_t](http://en.cppreference.com/w/cpp/utility/nullopt_t)

<code>hpx::register_startup_function</code>
<code>hpx::register_pre_shutdown_function</code>
<code>hpx::register_shutdown_function</code>
<code>hpx::get_num_localities</code>
<code>hpx::get_locality_name</code>

## `hpx/source_location.hpp`

The header `hpx/source_location.hpp`<sup>429</sup> corresponds to the C++ standard library header `source_location`<sup>430</sup>.

## Classes

Table 2.69: Classes of header `hpx/system_error.hpp`

Class	C++ standard
<code>hpx::source_location</code>	<code>std::source_location</code> <sup>431</sup>

## `hpx/system_error.hpp`

The header `hpx/system_error.hpp`<sup>432</sup> corresponds to the C++ standard library header `system_error`<sup>433</sup>.

<sup>429</sup> [http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/source\\_location.hpp](http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/source_location.hpp)

<sup>430</sup> [http://en.cppreference.com/w/cpp/header/source\\_location](http://en.cppreference.com/w/cpp/header/source_location)

<sup>431</sup> [http://en.cppreference.com/w/cpp/utility/source\\_location](http://en.cppreference.com/w/cpp/utility/source_location)

<sup>432</sup> [http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/system\\_error.hpp](http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/system_error.hpp)

<sup>433</sup> [http://en.cppreference.com/w/cpp/header/system\\_error](http://en.cppreference.com/w/cpp/header/system_error)

## Classes

Table 2.70: Classes of header `hpx/system_error.hpp`

Class	C++ standard
<code>hpx::error_code</code>	<code>std::error_code</code> <sup>434</sup>

## `hpx/task_block.hpp`

The header `hpx/task_block.hpp`<sup>435</sup> corresponds to the `task_block` feature in N4411<sup>436</sup>. See [Using task blocks](#) for more details on using task blocks.

## Classes

Table 2.71: Classes of header `hpx/task_block.hpp`

Class
<code>hpx::parallel::v2::task_canceled_exception</code>
<code>hpx::parallel::v2::task_block</code>

## Functions

Table 2.72: Functions of header `hpx/task_block.hpp`

Function
<code>hpx::parallel::v2::define_task_block</code>
<code>hpx::parallel::v2::define_task_block_restore_thread</code>

## `hpx/thread.hpp`

The header `hpx/thread.hpp`<sup>437</sup> corresponds to the C++ standard library header `thread`<sup>438</sup>. The functionality in this header is equivalent to the standard library thread functionality, with the exception that the *HPX* equivalents are implemented on top of lightweight threads and the *HPX* runtime.

<sup>434</sup> [http://en.cppreference.com/w/cpp/error/error\\_code](http://en.cppreference.com/w/cpp/error/error_code)

<sup>435</sup> [http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/task\\_block.hpp](http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/task_block.hpp)

<sup>438</sup> <http://en.cppreference.com/w/cpp/header/thread>

## Classes

Table 2.73: Classes of header hpx/thread.hpp

Class	C++ standard
hpx::thread	std::thread <sup>439</sup>
hpx::jthread	std::jthread <sup>440</sup>

## Functions

Table 2.74: Functions of header hpx/thread.hpp

Function
hpx::this_thread::yield
hpx::this_thread::get_id
hpx::this_thread::sleep_for
hpx::this_thread::sleep_until

## hpx/semaphore.hpp

The header `hpx/semaphore.hpp`<sup>441</sup> corresponds to the C++ standard library header `semaphore`<sup>442</sup>.

## Classes

Table 2.75: Classes of header hpx/semaphore.hpp

Class	C++ standard
hpx::binary_semaphore	std::counting_semaphore <sup>443</sup>
hpx::counting_semaphore	std::counting_semaphore <sup>444</sup>

## hpx/shared\_mutex.hpp

The header `hpx/shared_mutex.hpp`<sup>445</sup> corresponds to the C++ standard library header `shared_mutex`<sup>446</sup>.

<sup>439</sup> <http://en.cppreference.com/w/cpp/thread/thread>  
<sup>440</sup> <http://en.cppreference.com/w/cpp/thread/jthread>  
<sup>441</sup> <http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/semaphore.hpp>  
<sup>442</sup> <http://en.cppreference.com/w/cpp/header/semaphore>  
<sup>443</sup> [http://en.cppreference.com/w/cpp/thread/counting\\_semaphore](http://en.cppreference.com/w/cpp/thread/counting_semaphore)  
<sup>444</sup> [http://en.cppreference.com/w/cpp/thread/counting\\_semaphore](http://en.cppreference.com/w/cpp/thread/counting_semaphore)  
<sup>445</sup> [http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/shared\\_mutex.hpp](http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/shared_mutex.hpp)  
<sup>446</sup> [http://en.cppreference.com/w/cpp/header/shared\\_mutex](http://en.cppreference.com/w/cpp/header/shared_mutex)

## Classes

Table 2.76: Classes of header `hpx/shared_mutex.hpp`

Class	C++ standard
<code>hpx::shared_mutex</code>	<code>std::shared_mutex</code> <sup>447</sup>

## `hpx/stop_token.hpp`

The header `hpx/stop_token.hpp`<sup>448</sup> corresponds to the C++ standard library header `stop_token`<sup>449</sup>.

## Constants

Table 2.77: Constants of header `hpx/stop_token.hpp`

Constant	C++ standard
<code>hpx::nostopstate</code>	<code>std::nostopstate</code> <sup>450</sup>

## Classes

Table 2.78: Classes of header `hpx/stop_token.hpp`

Class	C++ standard
<code>hpx::stop_callback</code>	<code>std::stop_callback</code> <sup>451</sup>
<code>hpx::stop_source</code>	<code>std::stop_source</code> <sup>452</sup>
<code>hpx::stop_token</code>	<code>std::stop_token</code> <sup>453</sup>
<code>hpx::nostopstate_t</code>	<code>std::nostopstate_t</code> <sup>454</sup>

## `hpx/tuple.hpp`

The header `hpx/tuple.hpp`<sup>455</sup> corresponds to the C++ standard library header `tuple`<sup>456</sup>. `hpx::tuple` can be used in CUDA device code, unlike `std::tuple`.

<sup>447</sup> [http://en.cppreference.com/w/cpp/thread/shared\\_mutex](http://en.cppreference.com/w/cpp/thread/shared_mutex)

<sup>448</sup> [http://github.com/STEllAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/stop\\_token.hpp](http://github.com/STEllAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/stop_token.hpp)

<sup>449</sup> [http://en.cppreference.com/w/cpp/header/stop\\_token](http://en.cppreference.com/w/cpp/header/stop_token)

Function
<code>hpx::unwrap</code>
<code>hpx::unwrap_n</code>
<code>hpx::unwrap_all</code>
<code>hpx::unwrapping</code>
<code>hpx::unwrapping_n</code>
<code>hpx::unwrapping_all</code>

## `hpx/version.hpp`

The header `hpx/version.hpp`<sup>471</sup> provides version information about *HPX*.

<sup>468</sup> [http://en.cppreference.com/w/cpp/types/is\\_invocable](http://en.cppreference.com/w/cpp/types/is_invocable)

<sup>469</sup> [http://en.cppreference.com/w/cpp/types/is\\_invocable](http://en.cppreference.com/w/cpp/types/is_invocable)

<sup>470</sup> <http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/full/include/include/hpx/unwrap.hpp>

<sup>471</sup> <http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/libs/core/version/include/hpx/version.hpp>

## Macros

Table 2.85: Macros of header `hpx/version.hpp`

Macro
HPX_VERSION_MAJOR
HPX_VERSION_MINOR
HPX_VERSION_SUBMINOR
HPX_VERSION_FULL
HPX_VERSION_DATE
HPX_VERSION_TAG
HPX_AGAS_VERSION

## Functions

Table 2.86: Functions of header `hpx/version.hpp`

Function
<code>hpx::major_version</code>
<code>hpx::minor_version</code>
<code>hpx::subminor_version</code>
<code>hpx::full_version</code>
<code>hpx::full_version_as_string</code>
<code>hpx::tag</code>
<code>hpx::agas_version</code>
<code>hpx::build_type</code>
<code>hpx::build_date_time</code>

### `hpx/wrap_main.hpp`

The header `hpx/wrap_main.hpp`<sup>472</sup> does not provide any direct functionality but is used for implicitly using `main` as the runtime entry point. See [Re-use the `main\(\)` function as the main HPX entry point](#) for more details on implicitly starting the *HPX* runtime.

## 2.8.2 Full API

The full API of *HPX* is presented below. The listings for the public API above refer to the full documentation below.

---

**Note:** Most names listed in the full API reference are implementation details or considered unstable. They are listed mostly for completeness. If there is a particular feature you think deserves being in the public API we may consider promoting it. In general we prioritize making sure features corresponding to C++ standard library features are stable and complete.

---

<sup>472</sup> [http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/include/hpx/wrap\\_main.hpp](http://github.com/STELLAR-GROUP/hpx/blob/797c29fdce4df5b8051e633b8a24be94acd34bba/include/hpx/wrap_main.hpp)

## algorithms

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### `hpx/parallel/task_block.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parallel**

#### Functions

```
template<typename ExPolicy, typename F>
hpx::future<void> define_task_block(ExPolicy &&policy, F &&f)
```

Constructs a `task_block`, *tr*, using the given execution policy *policy*, and invokes the expression *f(tr)* on the user-provided object, *f*.

Postcondition: All tasks spawned from *f* have finished execution. A call to `define_task_block` may return on a different thread than that on which it was called.

---

**Note:** It is expected (but not mandated) that *f* will (directly or indirectly) call *tr.run(callable\_object)*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- **F** – The type of the user defined function to invoke inside the `define_task_block` (deduced). *F* shall be `MoveConstructible`.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **f** – The user defined function to invoke inside the task block. Given an lvalue *tr* of type `task_block`, the expression, (*void*)*f*(*tr*), shall be well-formed.

**Throws** An – `exception_list`, as specified in Exception Handling.

```
template<typename ExPolicy, typename F>
void define_task_block(ExPolicy &&policy, F &&f)
```

```
template<typename F>
void define_task_block(F &&f)
```

Constructs a `task_block`, *tr*, and invokes the expression *f(tr)* on the user-provided object, *f*. This version uses `parallel_policy` for task scheduling.

Postcondition: All tasks spawned from *f* have finished execution. A call to `define_task_block` may return on a different thread than that on which it was called.

---

**Note:** It is expected (but not mandated) that *f* will (directly or indirectly) call *tr.run(callable\_object)*.

---

**Template Parameters** **F** – The type of the user defined function to invoke inside the `define_task_block` (deduced). *F* shall be MoveConstructible.

**Parameters** **f** – The user defined function to invoke inside the task block. Given an lvalue *tr* of type `task_block`, the expression, `(void)f(tr)`, shall be well-formed.

**Throws** An `-exception_list`, as specified in Exception Handling.

```
template<typename ExPolicy, typename F>
util::detail::algorithm_result<ExPolicy>::type define_task_block_restore_thread(ExPolicy
    &&policy, F
    &&f)
```

Constructs a `task_block`, *tr*, and invokes the expression `f(tr)` on the user-provided object, *f*.

Postcondition: All tasks spawned from *f* have finished execution. A call to `define_task_block_restore_thread` always returns on the same thread as that on which it was called.

---

**Note:** It is expected (but not mandated) that *f* will (directly or indirectly) call `tr.run(callable_object)`.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- **F** – The type of the user defined function to invoke inside the `define_task_block` (deduced). *F* shall be MoveConstructible.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **f** – The user defined function to invoke inside the `define_task_block`. Given an lvalue *tr* of type `task_block`, the expression, `(void)f(tr)`, shall be well-formed.

**Throws** An `-exception_list`, as specified in Exception Handling.

```
template<typename F>
void define_task_block_restore_thread(F &&f)
```

Constructs a `task_block`, *tr*, and invokes the expression `f(tr)` on the user-provided object, *f*. This version uses `parallel_policy` for task scheduling.

Postcondition: All tasks spawned from *f* have finished execution. A call to `define_task_block_restore_thread` always returns on the same thread as that on which it was called.

---

**Note:** It is expected (but not mandated) that *f* will (directly or indirectly) call `tr.run(callable_object)`.

---

**Template Parameters** **F** – The type of the user defined function to invoke inside the `define_task_block` (deduced). *F* shall be MoveConstructible.

**Parameters** **f** – The user defined function to invoke inside the `define_task_block`. Given an lvalue *tr* of type `task_block`, the expression, `(void)f(tr)`, shall be well-formed.

**Throws** An `-exception_list`, as specified in Exception Handling.

namespace **v2**

```
template<typename ExPolicy = hpx::execution::parallel_policy>
```

```
class task_block
```

```
#include <task_block.hpp> The class task_block defines an interface for forking and joining paral-
```

lel tasks. The `define_task_block` and `define_task_block_restore_thread` function templates create an object of type `task_block` and pass a reference to that object to a user-provided callable object.

An object of class `task_block` cannot be constructed, destroyed, copied, or moved except by the implementation of the task region library. Taking the address of a `task_block` object via operator`&` or `addressof` is ill formed. The result of obtaining its address by any other means is unspecified.

A `task_block` is active if it was created by the nearest enclosing task block, where “task block” refers to an invocation of `define_task_block` or `define_task_block_restore_thread` and “nearest

enclosing” means the most recent invocation that has not yet completed. Code designated for execution in another thread by means other than the facilities in this section (e.g., using `thread` or `async`) are not enclosed in the task region and a `task_block` passed to (or captured by) such code is not active within that code. Performing any operation on a `task_block` that is not active results in undefined behavior.

The `task_block` that is active before a specific call to the `run` member function is not active within the asynchronous function that invoked `run`. (The invoked function should not, therefore, capture the `task_block` from the surrounding block.)

#### Example:

```
define_task_block([&](auto& tr) {
    tr.run([&] {
        tr.run([] { f(); });
    });
    ↪active
    define_task_block([&](auto& tr) {
        tr.run(f);
        // ...
    });
    // ...
});
```

**Template Parameters `ExPolicy`** – The execution policy an instance of a `task_block` was created with. This defaults to `parallel_policy`.

## Public Types

using `execution_policy` = `ExPolicy`

Refers to the type of the execution policy used to create the `task_block`.

## Public Functions

inline `execution_policy` const &`get_execution_policy`() const

Return the execution policy instance used to create this `task_block`

template<typename `F`, typename ...`Ts`>  
inline void `run`(`F` &&`f`, `Ts`&&... `ts`)

Causes the expression `f()` to be invoked asynchronously. The invocation of `f` is permitted to run on an unspecified thread in an unordered fashion relative to the sequence of operations following the call to `run(f)` (the continuation), or indeterminately sequenced within the same thread as the continuation.

The call to *run* synchronizes with the invocation of *f*. The completion of *f()* synchronizes with the next invocation of *wait* on the same *task\_block* or completion of the nearest enclosing task block (i.e., the *define\_task\_block* or *define\_task\_block\_restore\_thread* that created this task block).

Requires: *F* shall be MoveConstructible. The expression, *(void)f()*, shall be well-formed.

Precondition: this shall be the active *task\_block*.

Postconditions: A call to *run* may return on a different thread than that on which it was called.

---

**Note:** The call to *run* is sequenced before the continuation as if *run* returns on the same thread. The invocation of the user-supplied callable object *f* may be immediate or may be delayed until compute resources are available. *run* might or might not return before invocation of *f* completes.

---

**Throws** This – function may throw *task\_canceled\_exception*, as described in Exception Handling.

```
template<typename Executor, typename F, typename ...Ts>
inline void run(Executor &&exec, F &&f, Ts&&... ts)
```

Causes the expression *f()* to be invoked asynchronously using the given executor. The invocation of *f* is permitted to run on an unspecified thread associated with the given executor and in an unordered fashion relative to the sequence of operations following the call to *run(exec, f)* (the continuation), or indeterminately sequenced within the same thread as the continuation.

The call to *run* synchronizes with the invocation of *f*. The completion of *f()* synchronizes with the next invocation of *wait* on the same *task\_block* or completion of the nearest enclosing task block (i.e., the *define\_task\_block* or *define\_task\_block\_restore\_thread* that created this task block).

Requires: *Executor* shall be a type modeling the *Executor* concept. *F* shall be MoveConstructible. The expression, *(void)f()*, shall be well-formed.

Precondition: this shall be the active *task\_block*.

Postconditions: A call to *run* may return on a different thread than that on which it was called.

---

**Note:** The call to *run* is sequenced before the continuation as if *run* returns on the same thread. The invocation of the user-supplied callable object *f* may be immediate or may be delayed until compute resources are available. *run* might or might not return before invocation of *f* completes.

---

**Throws** This – function may throw *task\_canceled\_exception*, as described in Exception Handling. The function will also throw a *exception\_list* holding all exceptions that were caught while executing the tasks.

```
inline void wait()
```

Blocks until the tasks spawned using this *task\_block* have finished.

Precondition: this shall be the active *task\_block*.

Postcondition: All tasks spawned by the nearest enclosing task region have finished. A call to *wait* may return on a different thread than that on which it was called.

**Example:**

```
define_task_block([&](auto& tr) {
```

(continues on next page)

(continued from previous page)

```

    tr.run([&]{ process(a, w, x); });
    if (y < x) tr.wait(); // Wait if overlap between [w, x) and
    ↪ [y, z)
    process(a, y, z); // Process a[y] through a[z]
});

```

---

**Note:** The call to `wait` is sequenced before the continuation as if `wait` returns on the same thread.

---

**Throws** This – function may throw `task_canceled_exception`, as described in Exception Handling. The function will also throw a `exception_list` holding all exceptions that were caught while executing the tasks.

inline `ExPolicy &policy()`

Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active `task_block`.

inline `ExPolicy const &policy() const`

Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active `task_block`.

## hpx/parallel/algorithms/adjacent\_difference.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
inline std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>>::t
```

Assigns each value in the range given by `result` its corresponding element in the range `[first, last]` and the one preceding it except `*result`, which is assigned `*first`

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `op`.

**Note:** Complexity: Exactly  $(\text{last} - \text{first}) - 1$  application of the binary operator and  $(\text{last} - \text{first})$  assignments.

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  - **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of an forward iterator.
  - **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of an forward iterator.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
  - **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
  - **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
  - **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.

**Returns** The *adjacent\_difference* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The *adjacent\_find* algorithm returns an iterator to the last element in the output range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
inline std::enable_if_t<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>> t;
```

Assigns each value in the range given by `result` its corresponding element in the range [first, last] and the one preceding it except `*result`, which is assigned `*first`

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent\_difference* requires *Op* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

**Returns** The *adjacent\_difference* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *adjacent\_find* algorithm returns an iterator to the last element in the output range.

## hpx/parallel/algorithms/adjacent\_find.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename InIter, typename Pred = detail::equal_to>
InIter adjacent_find(InIter first, InIter last, Pred &&pred = Pred())
```

Searches the range [first, last) for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where *result* is the value returned

---

### Template Parameters

- **InIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename ExPolicy, typename FwdIter, typename Pred = detail::equal_to>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter>::type>::ty
```

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate *pred*

The comparison operations in the parallel *adjacent\_find* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *adjacent\_find* invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *adjacent\_find* is available if the user decides to provide their algorithm their own binary predicate *pred*.

---

**Note:** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where *result* is the value returned

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *adjacent\_find* algorithm returns a *hpx::future<InIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *InIter* otherwise. The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

## hpx/parallel/algorithms/all\_any\_none.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, FwdIter first, FwdIter last,
                                                               F &&f)
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *none\_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename InIter, typename F>
bool none_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *none\_of* algorithm returns a `bool`. The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, bool>::type any_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Checks if unary predicate *f* returns true for at least one element in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *any\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *any\_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `bool` otherwise. The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename InIter, typename F>
bool any_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate *f* returns true for at least one element in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *any\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `any_of` algorithm returns a `bool`. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, bool>::type all_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Checks if unary predicate `f` returns true for all elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `last - first` applications of the predicate `f`

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `all_of` requires `F` to meet the requirements of `CopyConstructible`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The *all\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename InIter, typename F>
bool all_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate *f* returns true for all elements in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *all\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *all\_of* algorithm returns a *bool*. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

## hpx/parallel/algorithms/copy.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy(ExPolicy &&policy, FwdIter1
first, FwdIter1 last, FwdIter2
dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Executed according to the policy.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2FwdIter2 copy(FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy* algorithm returns a *FwdIter2*. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy_n(ExPolicy &&policy, FwdIter1
first, Size count, FwdIter2
dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. Executed according to the policy.

The assignments in the parallel *copy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy\_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *copy\_n* algorithm returns Iterator in the destination range, pointing past the last element copied if *count*>0 or result otherwise.

---

```
template<typename FwdIter1, typename Size, typename FwdIter2FwdIter2 copy_n(FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range [*first*, *first* + *count*), starting from *first* and proceeding to *first* + *count* - 1., to another range beginning at *dest*.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy\_n* algorithm returns a *FwdIter2*. The *copy\_n* algorithm returns Iterator in the destination range, pointing past the last element copied if *count*>0 or result otherwise.

---

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Predhpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy_if(ExPolicy &&policy,
FwdIter1 first, FwdIter1 last,
FwdIter2 dest, Pred
&&pred)
```

Copies the elements in the range, defined by [*first*, *last*), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved. Executed according to the policy.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *f*.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *copy\_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *copy\_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename Pred>
FwdIter2 copy_if(FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.

## Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *copy\_if* algorithm returns a *FwdIter2*. The *copy\_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/count.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::difference_type>::type count(ExPolicy
    &&policy,
    FwdIter
    first,
    FwdIter
    last,
    T
    const
    &value)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*. Executed according to the policy.

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

---

**Note:** The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified

threads, and indeterminately sequenced within each thread.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to search for (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

**Returns** The `count` algorithm returns a `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIterB>::difference_type`. The `count` algorithm returns the number of elements satisfying the given criteria.

template<typename **InIter**, typename **T**>  
`std::iterator_traits<InIter>::difference_type count(InIter first, InIter last, T const &value)`

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given `value`.

---

**Note:** Complexity: Performs exactly `last - first` comparisons.

---

### Template Parameters

- **InIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

**Returns** The `count` algorithm returns a `difference_type` (where `difference_type` is defined by `std::iterator_traits<InIter>::difference_type`. The `count` algorithm returns the number of elements satisfying the given criteria.

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>

---

```
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::difference_type>::type count_if(ExPolicy
&&policy,
FwdIter first,
FwdIter last,
F
&&f)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true. Executed according to the policy.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

**bool pred(const Type &a);**

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *count\_if* algorithm returns *hpx::future<difference\_type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *std::iterator\_traits<FwdIter>::difference\_type*). The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename InIter, typename F>
std::iterator_traits<InIter>::difference_type count_if(InIter first, InIter last, F &&f)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **InIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *count\_if* algorithm returns *difference\_type* (where a *difference\_type* is defined by *std::iterator\_traits<InIter>::difference\_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

## hpx/parallel/algorithms/destroy.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type destroy(ExPolicy &&policy, FwdIter first, FwdIter last)
    Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last). Executed according to the policy.
```

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* operations.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *destroy* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename FwdIter>
void destroy(FwdIter first, FwdIter last)
    Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).
```

---

**Note:** Complexity: Performs exactly *last - first* operations.

---

**Template Parameters FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *destroy* algorithm returns a *void*

```
template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type destroy_n(ExPolicy &&policy, FwdIter first, Size count)
```

Destroys objects of type typename iterator\_traits<ForwardIt>::value\_type in the range [first, first + count). Executed according to the policy.

The operations in the parallel *destroy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* operations, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *destroy\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *destroy\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename FwdIter, typename Size>
FwdIter destroy_n(FwdIter first, Size count)
```

Destroys objects of type typename iterator\_traits<ForwardIt>::value\_type in the range [first, first + count).

---

**Note:** Complexity: Performs exactly *count* operations, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

## Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *destroy\_n* algorithm returns a *FwdIter*. The *destroy\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

## hpx/parallel/algorithms/ends\_with.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename InIter1, typename InIter2, typename Pred>
bool ends_with(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred)
```

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel *ends\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

## Template Parameters

- **InIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a input iterator.
- **Pred** – The binary predicate that compares the projected elements.

## Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Refers to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.

**Returns** The *ends\_with* algorithm returns *bool*. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &&policy, FwdIter1  
first1, FwdIter1 last1, FwdIter2  
first2, FwdIter2 last2, Pred  
&&pred)
```

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel `ends_with` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `ends_with` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear: at most  $\min(N_1, N_2)$  applications of the predicate and both projections.

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  - **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
  - **FwdIter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a forward iterator.
  - **Pred** – The binary predicate that compares the projected elements.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
  - **first1** – Refers to the beginning of the source range.
  - **last1** – Refers to the end of the source range.
  - **first2** – Refers to the beginning of the destination range.
  - **last2** – Refers to the end of the destination range.
  - **pred** – Specifies the binary predicate function (or function object) which will be invoked for

**Returns** The `ends_with` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `ends_with` algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

## hpx/parallel/algorithms/equal.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1
last1, FwdIter2 first2, FwdIter2 last2, Pred &&op
= Pred())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to the policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\min(last1 - first1, last2 - first2))$  applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1),  $*i$  equals  $*(first2 + (i - first1))$ . This overload of *equal* uses operator== to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

**Returns** The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1
last1, FwdIter2 first2, FwdIter2 last2)
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise. Executed according to policy.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\min(last1 - first1, last2 - first2))$  applications of the predicate `std::equal_to`.

---

---

**Note:** The two ranges are considered equal if, for every iterator `i` in the range `[first1, last1)`, `*i` equals `*(first2 + (i - first1))`. This overload of `equal` uses operator`==` to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1
last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\min(last1 - first1, last2 - first2))$  applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1),  $*i$  equals  $(first2 + (i - first1))$ . This overload of *equal* uses operator $\equiv$  to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

**Returns** The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1
last1, FwdIter2 first2)
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to policy.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $last1 - first1$  applications of the predicate `op`.

---

---

**Note:** The two ranges are considered equal if, for every iterator `i` in the range [first1, last1), `*i` equals `*(first2 + (i - first1))`. This overload of `equal` uses operator`==` to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

---

**Note:** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses operator== to determine if two elements are equal.

---

## Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

## Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

**Returns** The `equal` algorithm returns a `bool`. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```
template<typename FwdIter1, typename FwdIter2>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise.

---

**Note:** Complexity: At most `min(last1 - first1, last2 - first2)` applications of the predicate `std::equal_to`.

---

**Note:** The two ranges are considered equal if, for every iterator `i` in the range `[first1, last1)`, `*i` equals `*(first2 + (i - first1))`. This overload of `equal` uses operator`==` to determine if two elements are equal.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The `equal` algorithm returns a `bool`. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, first2 + (last1 - first1))`, and false otherwise.

---

**Note:** Complexity: At most `last1 - first1` applications of the predicate `op`.

---

---

**Note:** The two ranges are considered equal if, for every iterator i in the range [first1, last1), \*i equals \*(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

**Returns** The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

## hpx/parallel/algorithms/exclusive\_scan.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename InIter, typename OutIter, typename T>
OutIter exclusive_scan(InIter first, InIter last, OutIter dest, T init)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, init, \*first, ..., \*(first + (i - result) - 1))

The reduce operations in the parallel *exclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the  $i$ th input element in the  $i$ th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate `std::plus<T>`.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

**Returns** The *exclusive\_scan* algorithm returns *OutIter*. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type exclusive_scan(ExPolicy &&policy, FwdIter1
first, FwdIter1 last, FwdIter2 dest,
T init)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, init, \*first, ..., \*(first + (i - result) - 1))

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate `std::plus<T>`.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

**Returns** The *exclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **T**, typename **Op**>  
**OutIter** **exclusive\_scan**(*InIter* first, *InIter* last, *OutIter* dest, *T* init, *Op*  $\&\&op$ )

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*K), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*M, ..., *a*N)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The *exclusive\_scan* algorithm returns *OutIter*. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type exclusive_scan(ExPolicy &&policy, FwdIter1
first, FwdIter1 last, FwdIter2 dest,
T init, Op &&op)
```

---

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the  $i$ th input element in the  $i$ th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,  $a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
  - $\text{op}(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_1, \dots, a_K), \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_M, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `exclusive_scan` algorithm returns a `hpx::future<OutIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `OutIter` otherwise. The `exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/fill.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy>::type fill(ExPolicy &&policy, FwdIter first, FwdIter last, T value)
```

Assigns the given value to the elements in the range [first, last). Executed according to the policy.

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill* algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```
template<typename FwdIter, typename T>
void fill(FwdIter first, FwdIter last, T value)
```

Assigns the given value to the elements in the range [first, last).

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill* algorithm returns a `void`.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type fill_n(ExPolicy &&policy, FwdIter first, Size count,
                                                               T value)
```

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise. Executed according to the policy.

The comparisons in the parallel *fill\_n* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel *fill\_n* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, for count > 0.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill\_n* algorithm returns a `hpx::future<void>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *void*).

```
template<typename FwdIter, typename Size, typename T>
FwdIter fill_n(FwdIter first, Size count, T value)
```

Assigns the given value *value* to the first *count* elements in the range beginning at *first* if *count* > 0. Does nothing otherwise.

---

**Note:** Complexity: Performs exactly *count* assignments, for *count* > 0.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill\_n* algorithm returns a *FwdIter*.

## hpx/parallel/algorithms/find.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find(ExPolicy &&policy, FwdIter first, FwdIter last,
T const &val)
```

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the operator==().

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to find (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

**Returns** The *find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename InIter, typename T>
InIter find(InIter first, InIter last, T const &val)
```

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

**Note:** Complexity: At most last - first applications of the operator==().

### Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.

- **T** – The type of the value to find (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

**Returns** The *find* algorithm returns a *InIter*. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find_if(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range [first, last) for which predicate *f* returns true. Executed according to the policy.

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *find\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename InIter, typename F>
InIter find_if(InIter first, InIter last, F &&f)
```

Returns the first element in the range [first, last) for which predicate *f* returns true.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

### Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *find\_if* algorithm returns a *InIter*. The *find\_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find_if_not(ExPolicy &&policy, FwdIter first,
FwdIter last, F &&f)
```

Returns the first element in the range [first, last) for which predicate *f* returns false. Executed according to the policy.

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

`bool pred(const Type &a);`

The signature does not need to have **const** &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *find\_if\_not* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if\_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename FwdIter, typename F>
FwdIter find_if_not(FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range [first, last) for which predicate *f* returns false.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const `&`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `find_if_not` algorithm returns a `FwdIter`. The `find_if_not` algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_end(ExPolicy &&policy, FwdIter1 first1,
FwdIter1 last1, FwdIter2 first2, FwdIter2
last2, Pred &&op = Pred())
```

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate `op` to compare elements. Executed according to the policy.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

---

**Note:** Complexity: at most  $S*(N-S+1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

**Returns** The *find\_end* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence  $[first2, last2]$  in range  $[first, last]$ . If the length of the subsequence  $[first2, last2]$  is greater than the length of the range  $[first1, last1]$ , *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_end(ExPolicy &&policy, FwdIter1 first1,
                                                               FwdIter1 last1, FwdIter2 first2, FwdIter2
                                                               last2)
```

Returns the last subsequence of elements  $[first2, last2]$  found in the range  $[first, last]$ . Elements are compared using *operator==*. Executed according to the policy.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $S*(N-S+1)$  comparisons where  $S = \text{distance}(first2, last2)$  and  $N = \text{distance}(first1, last1)$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

**Returns** The *find\_end* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2] in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter1 find_end(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
    Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate op to compare elements.
```

This overload of *find\_end* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $S^*(N-S+1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

**Returns** The *find\_end* algorithm returns a *FwdIter1*. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2] in range [first, last). If the length of the subsequence [first2, last2] is greater than the length of the range [first1, last1], *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename FwdIter1, typename FwdIter2>
FwdIter1 find_end(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns the last subsequence of elements [first2, last2] found in the range [first, last). Elements are compared using *operator==*.

---

**Note:** Complexity: at most  $S*(N-S+1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

**Returns** The *find\_end* algorithm returns a *FwdIter1*. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2] in range [first, last). If the length of the subsequence [first2, last2] is greater than the length of the range [first1, last1], *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
```

---

```
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_first_of(ExPolicy &&policy, FwdIter1 first,
FwdIter1 last, FwdIter2 s_first,
FwdIter2 s_last, Pred &&op =
Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses binary predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `find_first_of` algorithm returns a `hpx::future<FwdIter1>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter1` otherwise. The `find_first_of` algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s\_first, s\_last). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, last is also returned.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_first_of(ExPolicy &&policy, FwdIter1 first,
                                                                     FwdIter1 last, FwdIter2 s_first,
                                                                     FwdIter2 s_last)
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Elements are compared using `operator==`. Executed according to the policy.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

**Returns** The *find\_first\_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter1* otherwise. The *find\_first\_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s\_first, s\_last). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, last is also returned.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter1 find_first_of(FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses binary predicate *op* to compare elements.

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

<code>bool pred(const Type1 &amp;a, const Type2 &amp;b);</code>
---

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and

*FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

**Returns** The *find\_first\_of* algorithm returns a *FwdIter1*. The *find\_first\_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s\_first, s\_last). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

```
template<typename FwdIter1, typename FwdIter2>
FwdIter1 find_first_of(FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last)
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Elements are compared using *operator==*.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

**Returns** The *find\_first\_of* algorithm returns a *FwdIter1*. The *find\_first\_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s\_first, s\_last). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

## hpx/parallel/algorithms/for\_each.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename InIter, typename F>
F for_each(InIter first, InIter last, F &&f)
```

Applies *f* to the result of dereferencing every iterator in the range [first, last).

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

---

**Note:** Complexity: Applies *f* exactly *last - first* times.

---

### Template Parameters

- **InIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). *F* must meet requirements of *MoveConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have *const&*. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** *f*.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, void>::type for_each(ExPolicy &&policy, FwdIter first, FwdIter last,
F &&f)
```

Applies *f* to the result of dereferencing every iterator in the range [first, last). Executed according to the policy.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies  $f$  exactly  $last - first$  times.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have *const&*. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *for\_each* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns void otherwise.

```
template<typename InIter, typename Size, typename F>
InIter for_each_n(InIter first, Size count, F &&f)
```

Applies *f* to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

---

**Note:** Complexity: Applies *f* exactly *count* times.

---

### Template Parameters

- **InIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply  $f$  to.
- **F** – The type of the function/function object to use (deduced). F must meet requirements of *MoveConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at  $first$  the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns**  $first + count$  for non-negative values of *count* and *first* for negative values.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename FExPolicy, FwdIter>::type for_each_n(ExPolicy &&policy, FwdIter first, Size count, F &&f)
```

Applies  $f$  to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1. Executed according to the policy.

If  $f$  returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator,  $f$  may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each\_n* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies  $f$  exactly *count* times.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply  $f$  to.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each_n` requires  $F$  to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The `for_each_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *first + count* for non-negative values of *count* and *first* for negative values.

## hpx/parallel/algorithms/for\_loop.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

### Functions

```
template<typename I, typename ...Args>
void for_loop(std::decay_t<I> first, I last, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the  $\text{args}$  parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the  $\text{args}$  parameter pack excluding  $f$ , an additional argument is passed to each application of  $f$  as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, std::decay_t<I> first, I
last, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires:  $I$  shall be an integral type or meet the requirements of an input iterator type. The  $\text{args}$  parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of *MoveConstructible*.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the  $\text{args}$  parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the  $\text{args}$  parameter pack excluding  $f$ , an additional argument is passed to each application of  $f$  as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The *for\_loop* algorithm returns a *hpx::future<void>* if the execution policy is of type *hpx::execution::sequenced\_task\_policy* or *hpx::execution::parallel\_task\_policy* and returns *void* otherwise.

```
template<typename I, typename S, typename ...Args>
void for_loop_strided(std::decay_t<I> first, I last, S stride, Args&&... args)
```

The *for\_loop\_strided* implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble *for\_each* from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of *for\_loop* without specifying an execution policy is equivalent to specifying *hpx::execution::seq* as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using *advance* and *distance*.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if  $I$  has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename S, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy &&policy, std::decay_t<I>
first, I last, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires:  $I$  shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of *MoveConstructible*.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding  $f$ , an additional argument is passed to each application of  $f$  as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The `for_loop_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```
template<typename I, typename Size, typename ...Args>
void for_loop_n(I first, Size size, Args&&... args)
```

The `for_loop_n` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop_n` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires:** *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

**Effects:** Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

#### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename Size, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_n(ExPolicy &&policy, I first, Size size,
                                                       Args&&... args)
```

The `for_loop_n` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires:  $I$  shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of `MoveConstructible`.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The `for_loop_n` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

template<typename I, typename Size, typename S, typename ...Args>

```
void for_loop_n_strided(I first, Size size, S stride, Args&&... args)
```

The `for_loop_n_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

#### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.

- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if *I* has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have *const&*. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename Size, typename S, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_n_strided(ExPolicy &&policy, I first, Size
size, S stride, Args&&... args)
```

The *for\_loop\_n\_strided* implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble *for\_each* from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using *advance* and *distance*.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The `for_loop_n_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

## hpx/parallel/algorithms/for\_loop\_induction.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

### Functions

```
template<typename T>
constexpr hpx::parallel::v2::detail::induction_stride_helper<T> induction(T &&value, std::size_t
                                                               stride)
```

The function template returns an induction object of unspecified type having a value type and encapsulating an initial value *value* of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence *S* computes an induction value from an induction variable and ordinal position *p* within *S* by the formula *i* + *p* \* *stride* if a stride was specified or *i* + *p* otherwise. This induction value is passed to the element access function.

If the *value* argument to *induction* is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of  $i + n * \text{stride}$  to the live-out object upon return, where  $n$  is the number of elements in the input range.

**Template Parameters** **T** – The value type to be used by the induction object.

**Parameters**

- **value** – [in] The initial value to use for the induction object
- **stride** – [in] The (optional) stride to use for the induction object (default: 1)

**Returns** This returns an induction object with value type *T*, initial value *value*, and (if specified) stride *stride*. If *T* is an lvalue of non-const type, *value* is used as the live-out object for the induction object; otherwise there is no live-out object.

namespace **parallel**

namespace **v2**

## **hpx/parallel/algorithms/for\_loop\_reduction.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

### Functions

```
template<typename T, typename Op>
constexpr hpx::parallel::v2::detail::reduction_helper<T, std::decay_t<Op>> reduction(T &var, T const
&identity, Op
&&combiner)
```

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the reduction object's combiner operation until a single value remains, which is then assigned back to the live-out object.

*T* shall meet the requirements of *CopyConstructible* and *MoveAssignable*. The expression

<code>var = combiner(var, var)</code>
---------------------------------------

shall be well formed.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is plus<T>, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

---

#### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

#### Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation.
- **combiner** – [in] The binary function (object) used to perform a pairwise reduction on the elements.

**Returns** This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

namespace **parallel**

namespace **v2**

## **hpx/parallel/algorithms/generate.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate(ExPolicy &&policy, FwdIter first, FwdIter
last, F &&f)
```

Assign each element in range [first, last) a value generated by the given function object *f*

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate_n(ExPolicy &&policy, FwdIter first, Size count, F &&f)
```

Assigns each element in range [first, first+count) a value generated by the given function object *g*.

The assignments in the parallel *generate\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *count* invocations of *f* and assignments, for *count* > 0.

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

## hpx/parallel/algorithms/includes.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, bool>::type::type includes(ExPolicy &&policy, FwdIter1 first1,
                                                               FwdIter1 last1, FwdIter2 first2, FwdIter2
                                                               last2, Pred &&op = Pred())
```

Returns true if every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** At most  $2*(N1+N2-1)$  comparisons, where  $N1 = \text{std::distance(first1, last1)}$  and  $N2 = \text{std::distance(first2, last2)}$ .

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

**Returns** The *includes* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *includes* algorithm returns true every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty.

## hpx/parallel/algorithms/inclusive\_scan.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename OutIter>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, \*first, ..., \*(first + (i - result))).

The reduce operations in the parallel *inclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *inclusive\_scan* algorithm returns *OutIter*. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type inclusive_scan(ExPolicy &&policy, FwdIter1
first, FwdIter1 last, FwdIter2
dest)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, \*first, ..., \*(first + (i - result))).

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *inclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename Op>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest, Op &&op)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM( $op, *first, \dots, *(first + (i - result))$ ).

The reduce operations in the parallel *inclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the  $i$ th input element in the  $i$ th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate  $op$ .

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)

- 
- GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The *inclusive\_scan* algorithm returns *OutIter*. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type inclusive_scan(ExPolicy &&policy, FwdIter1
                                                               first, FwdIter1 last, FwdIter2 dest,
                                                               Op &&op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(op, \*first, ..., \*(first + (i - result))).

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

---

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename T, typename Op>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest, Op &&op, T init)

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init,  $*first, \dots, *(first + (i - result))$ ).
```

The reduce operations in the parallel `inclusive_scan` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the  $i$ th input element in the  $i$ th sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as:

---

- *a*<sub>1</sub> when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>K</sub>), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>M</sub>, ..., *a*<sub>N</sub>)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The *inclusive\_scan* algorithm returns *OutIter*. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Op>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type inclusive_scan(ExPolicy &&policy, FwdIter1
first, FwdIter1 last, FwdIter2 dest,
T init, Op &&op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *init*, \**first*, ..., \*(*first* + (*i* - result))).

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,      *a*1,      ... ,      *a*K),      GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*M, ..., *a*N)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The *inclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/is\_heap.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, bool>::type is_heap(ExPolicy &&policy, RandIter first, RandIter
last, Comp &&comp = Comp())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator`<`).

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

**Returns** The *is\_heap* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *is\_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, RandIter>::type is_heap_until(ExPolicy &&policy, RandIter first,
RandIter last, Comp &&comp = Comp())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = *last - first*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to *bool*, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

**Returns** The *is\_heap\_until* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter* otherwise. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*) is a max heap.

## hpx/parallel/algorithms/is\_partitioned.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Pred>
bool is_partitioned(FwdIter first, FwdIter last, Pred &&pred)
```

Determines if the range [first, last) is partitioned.

---

**Note:** Complexity: at most ( $N$ ) predicate evaluations where  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *is\_partitioned* algorithm returns *bool*. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range [first, last) contains less than two elements, the function is always true.

```
template<typename ExPolicy, typename FwdIter, typename Pred>
util::detail::algorithm_result<ExPolicy, bool>::type is_partitioned(ExPolicy &&policy, FwdIter first,
FwdIter last, Pred &&pred)
```

Determines if the range [first, last) is partitioned.

The predicate operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most ( $N$ ) predicate evaluations where  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). *Pred* must be *CopyConstructible* when using a parallel policy.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *is\_partitioned* algorithm returns a `hpx::future<bool>` if the execution policy is of type *task\_execution\_policy* and returns `bool` otherwise. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range  $[\text{first}, \text{last})$  contains less than two elements, the function is always true.

## hpx/parallel/algorithms/is\_sorted.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
bool is_sorted(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is\_sorted* algorithm executes in sequential order in the calling thread.

---

**Note:** Complexity: at most ( $N+S-1$ ) comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .  $S = \text{number of partitions}$

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *is\_sorted* algorithm returns a *bool*. The *is\_sorted* algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_sorted(ExPolicy &&policy, FwdIter
first, FwdIter last, Pred
&&pred = Pred())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is\_sorted* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_sorted* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .  $S = \text{number of partitions}$

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is\_sorted* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *is\_sorted* algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The *is\_sorted* algorithm returns a `bool` if each element in the sequence  $[\text{first}, \text{last}]$  satisfies the predicate passed. If the range  $[\text{first}, \text{last}]$  contains less than two elements, the function always returns true.

```
template<typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
FwdIter is_sorted_until(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range  $[\text{first}, \text{last}]$  that is not sorted. Uses a predicate to compare elements or the `less` operator.

The comparison operations in the parallel *is\_sorted\_until* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .  $S = \text{number of partitions}$

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of an optional function/function object to use.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `is_sorted_until` algorithm returns a `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, `last` is returned.

```
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type is_sorted_until(ExPolicy &&policy,
                                    FwdIter first,
                                    FwdIter last, Pred
                                    &&pred = Pred())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the `<` operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{distance(first, last)}$ .  $S = \text{number of partitions}$

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, `last` is returned.

## hpx/parallel/algorithms/lexicographical\_compare.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

```
template<typename InIter1, typename InIter2, typename Pred>
bool lexicographical_compare(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred)
    Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a
    provided predicate to compare elements.
```

The comparison operations in the parallel `lexicographical_compare` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std}::\text{distance}(\text{first1}, \text{last})$  and  $N2 = \text{std}::\text{distance}(\text{first2}, \text{last2})$ .

---

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
- An empty range is lexicographically *less* than any non-empty range

- Two empty ranges are lexicographically *equal*
- 

### Template Parameters

- **InIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to

**Returns** The *lexicographically\_compare* algorithm returns a returns *bool* if the execution policy object is not passed in. The *lexicographically\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```
template<typename FwdIter1, typename FwdIter2, typename Pred>
util::detail::algorithm_result<ExPolicy, bool>::type lexicographical_compare(ExPolicy &&policy,
FwdIter1 first1, FwdIter1
last1, FwdIter2 first2,
FwdIter2 last2, Pred
&&pred)
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std::distance(first1, last)}$  and  $N2 = \text{std::distance(first2, last2)}$ .

---

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
  - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
  - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
  - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
  - An empty range is lexicographically *less* than any non-empty range
  - Two empty ranges are lexicographically *equal*
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to

**Returns** The *lexicographically\_compare* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *lexicographically\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

## hpx/parallel/algorithms/make\_heap.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename RndIter, typename Comp>
util::detail::algorithm_result<ExPolicy>::type make_heap(ExPolicy &&policy, RndIter first, RndIter last,
                                                       Comp &&comp)
```

Constructs a *max heap* in the range [first, last).

The predicate operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *sequential\_execution\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *parallel\_execution\_policy* or *parallel\_task\_execution\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (3\*N) comparisons where N = distance(first, last).

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```
bool comp(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *make\_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task\_execution\_policy* and returns *void* otherwise.

```
template<typename ExPolicy, typename RndIter>
```

---

`hpx::parallel::util::detail::algorithm_result<ExPolicy>::type make_heap(ExPolicy &&policy, RndIter first, RndIter last)`

Constructs a *max heap* in the range [first, last). Uses the operator < for comparisons.

The predicate operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *sequential\_execution\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *parallel\_execution\_policy* or *parallel\_task\_execution\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (3\*N) comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

**Returns** The *make\_heap* algorithm returns a `hpx::future<void>` if the execution policy is of type *task\_execution\_policy* and returns `void` otherwise.

## hpx/parallel/algorithms/merge.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename RandIter1, typename RandIter2, typename RandIter3,
typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, RandIter3>::type merge(ExPolicy &&policy, RandIter1 first1,
                                                               RandIter1 last1, RandIter2 first2, RandIter2
                                                               last2, RandIter3 dest, Comp &&comp =
                                                               Comp())
```

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(\text{first1}, \text{last1}) + \text{std}::\text{distance}(\text{first2}, \text{last2}))$  applications of the comparison *comp* and the each projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of an random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of an random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

**Returns** The *merge* algorithm returns a `hpx::future<RandIter3>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter3* otherwise. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = detail::less>

---

`util::detail::algorithm_result<ExPolicy>::type inplace_merge(ExPolicy &&policy, RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())`

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel *inplace\_merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *inplace\_merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs O(std::distance(first, last)) applications of the comparison *comp* and the each projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace\_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

**Returns** The *inplace\_merge* algorithm returns a `hpx::future<void>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `void` otherwise. The *in-place\_merge* algorithm returns the source iterator *last*

## hpx/parallel/algorithms/minmax.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename F>
FwdIter min_element(FwdIter first, FwdIter last, F &&f)
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *min\_element* algorithm returns *FwdIter*. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type min_element(ExPolicy &&policy, FwdIter first,
                                                               FwdIter last, F &&f)
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min\_element* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *min\_element* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename FwdIter, typename F>
FwdIter max_element(FwdIter first, FwdIter last, F &&f)
```

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *max\_element* algorithm returns *FwdIter*. The *max\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type max_element(ExPolicy &&policy, FwdIter first,
FwdIter last, F &&f)
```

Removes all elements satisfying specific criteria from the range Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *max\_element* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *max\_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *max\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename FwdIter, typename F>
minmax_element_result<FwdIter> minmax_element(FwdIter first, FwdIter last, F &&f)
```

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns** The *minmax\_element* algorithm returns a *minmax\_element\_result<FwdIter>*. The *minmax\_element* algorithm returns a pair consisting of an iterator to the smallest element as

the min element and an iterator to the largest element as the max element. Returns minmax\_element\_result<FwdIter>{first, first} if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, minmax_element_result<FwdIter>>::type minmax_element(ExPolicy
    &&policy,
    FwdIter
    first,
    FwdIter
    last, F
    &&f)
```

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *minmax\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *minmax\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to *std::less*. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `minmax_element` algorithm returns a `minmax_element_result<FwdIter><FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `minmax_element_result<FwdIter>` otherwise. The `minmax_element` algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns `std::make_pair(first, first)` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

## hpx/parallel/algorithms/mismatch.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy &&policy,
FwdIter1 first1,
FwdIter1 last1,
FwdIter2 first2,
FwdIter2 last2, Pred
&&op = Pred())
```

Returns true if the range [first1, last1) is mismatch to the range [first2, last2), and false otherwise.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate *f*. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no applications of the predicate *f* are made.

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range [first1, last1),  $*i$  mismatch  $*(\text{first2} + (\text{i} - \text{first1}))$ . This overload of `mismatch` uses operator`==` to determine if two elements are mismatch.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

**Returns** The *mismatch* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *mismatch* algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range [first1, last1) does not mismatch the length of the range [first2, last2), it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy &&policy,
FwdIter1 first1,
FwdIter1 last1,
FwdIter2 first2, Pred
&&op = Pred())
```

Returns std::pair with iterators to the first two non-equivalent elements.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *f*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

**Returns** The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `std::pair<FwdIter1, FwdIter2>` otherwise. The *mismatch* algorithm returns the first mismatching pair of elements from two ranges: one defined by  $[first1, last1)$  and another defined by  $[first2, last2)$ .

## hpx/parallel/algorithms/move.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type move(ExPolicy &&policy, FwdIter1 first, FwdIter1
last, FwdIter2 dest)
```

Moves the elements in the range [first, last), to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* move assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *move* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

## hpx/parallel/algorithms/nth\_element.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandomIt, typename Pred>
void nth_element(RandomIt first, RandomIt nth, RandomIt last, Pred &&pred)
```

`nth_element` is a partial sorting algorithm that rearranges elements in  $[first, last]$  such that the element pointed at by `nth` is changed to whatever element would occur in that position if  $[first, last]$  were sorted and all of the elements before this new `nth` element are less than or equal to the elements after the new `nth` element.

The comparison operations in the parallel `nth_element` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in `std::distance(first, last)` on average.  $O(N)$  applications of the predicate, and  $O(N \log N)$  swaps, where  $N = last - first$ .

---

#### Template Parameters

- **RandomIt** – The type of the source begin, `nth`, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to `std::less<>`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type must be such that an object of type `randomIt` can be dereferenced and then implicitly converted to `Type`. This defaults to `std::less<>`.

**Returns** The `nth_element` algorithms returns nothing.

```
template<typename ExPolicy, typename RandomIt, typename Pred>
```

```
void nth_element(ExPolicy &&policy, RandomIt first, RandomIt nth, RandomIt last, Pred &&pred)
```

*nth\_element* is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by *nth* is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element.

The comparison operations in the parallel *nth\_element* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source begin, *nth*, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to std::less<>.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

**Returns** The *nth\_element* algorithms returns nothing.

## hpx/parallel/algorithms/partial\_sort.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandIter, typename Comp>
void partial_sort(RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

---

**Note:** Complexity: Approximately (last - first) \* log(middle - first) comparisons.

---

#### Template Parameters

- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to `detail::less`.

**Returns** The `partial_sort` algorithm returns nothing.

```
template<typename ExPolicy, typename RandIter, typename Comp>
util::detail::algorithm_result_t<ExPolicy> partial_sort(ExPolicy &&policy, RandIter first, RandIter
                                                       middle, RandIter last, Comp &&comp = Comp())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

---

**Note:** Complexity: Approximately (last - first) \* log(middle - first) comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

**Returns** The *partial\_sort* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns void otherwise.

## [hpx/parallel/algorithms/partial\\_sort\\_copy.hpp](#)

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename RandIter, typename Comp>
RandIter partial_sort_copy(InIter first, InIter last, RandIter d_first, RandIter d_last, Comp &&comp = Comp())
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d\_first, d\_last). At most d\_last - d\_first of the elements are placed sorted to the range [d\_first, d\_first + n) where n is the number of elements to sort (n = min(last - first, d\_last - d\_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(Nlog(min(D,N))), where N = std::distance(first, last) and D = std::distance(d\_first, d\_last) comparisons.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **d\_first** – Refers to the beginning of the destination range.
- **d\_last** – Refers to the end of the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to `detail::less`.

**Returns** The `partial_sort_copy` algorithm returns a returns `RandomIt`. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. `d_first + min(last - first, d_last - d_first)`

```
template<typename ExPolicy, typename FwdIter, typename RandIter, typename Comp>
parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> partial_sort_copy(ExPolicy &&policy,
                                                                           FwdIter first, FwdIter
                                                                           last, RandIter d_first,
                                                                           RandIter d_last, Comp
                                                                           &&comp = Comp())
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d\_first, d\_last). At most `d_last - d_first` of the elements are placed sorted to the range [d\_first, `d_first + n`] where n is the number of elements to sort (`n = min(last - first, d_last - d_first)`).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(\min(D, N)))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  and  $D = \text{std}::\text{distance}(\text{d\_first}, \text{d\_last})$  comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **d\_first** – Refers to the beginning of the destination range.
- **d\_last** – Refers to the end of the destination range.
- **comp** – comp is a callable object. The return value of the(INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

**Returns** The *partial\_sort\_copy* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandomIt* otherwise. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e.  $d\_first + \min(last - first, d\_last - d\_first)$

## hpx/parallel/algorithms/partition.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Pred, typename Proj>
FwdIter partition(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, Proj &&proj)
Reorders the elements in the range [first, last) in such a way that all elements for which the predicate pred
returns true precede the elements for which the predicate pred returns false. Relative order of the elements
is not preserved.
```

The assignments in the parallel *partition* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $2 * (last - first)$  swaps. Exactly  $last - first$  applications of the predicate and projection.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition* algorithm returns *FwdIter*. The *partition* algorithm returns the iterator to the first element of the second group.

```
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj>
util::detail::algorithm_result_t<ExPolicy, FwdIter> partition(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, Proj &&proj)
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * (\text{last} - \text{first})$  swaps. Exactly *last - first* applications of the predicate and projection.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter* otherwise. The *partition* algorithm returns the iterator to the first element of the second group.

```
template<typename BidirIter, typename F, typename Proj>
BidirIter stable_partition(BidirIter first, BidirIter last, F &&f, Proj &&proj)
```

Permutates the elements in the range [first, last) such that there exists an iterator *i* such that for every iterator *j* in the range [first, *i*)  $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}$ , and for every iterator *k* in the range [*i*, last),  $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) = \text{false}$

The invocations of *f* in the parallel *stable\_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) * \log(\text{last} - \text{first})$  swaps, but only linear number of swaps if there is enough extra memory. Exactly *last - first* applications of the predicate and projection.

---

#### Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `BidirIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `stable_partition` algorithm returns an iterator *i* such that for every iterator *j* in the range [first, *i*),  $f(*j) \neq \text{false}$  `INVOKE(f, INVOKE(proj, *j)) \neq \text{false}`, and for every iterator *k* in the range [*i*, last),  $f(*k) == \text{false}$  `INVOKE(f, INVOKE(proj, *k)) == \text{false}. The relative order of the elements in both groups is preserved.`

```
template<typename ExPolicy, typename BidirIter, typename F, typename Proj>
util::detail::algorithm_result_t<ExPolicy, BidirIter> stable_partition(ExPolicy &&policy, BidirIter first,
BidirIter last, F &&f, Proj
&&proj)
```

Permutes the elements in the range [first, last) such that there exists an iterator *i* such that for every iterator *j* in the range [first, *i*) `INVOKE(f, INVOKE(proj, *j)) \neq \text{false}, and for every iterator k in the range [i, last), INVOKE(f, INVOKE(proj, *k)) == \text{false}`

The invocations of *f* in the parallel `stable_partition` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The invocations of *f* in the parallel `stable_partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) * \log(\text{last} - \text{first})$  swaps, but only linear number of swaps if there is enough extra memory. Exactly *last - first* applications of the predicate and projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `BidirIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

**Returns** The `stable_partition` algorithm returns an iterator `i` such that for every iterator `j` in the range `[first, i)`, `f(*j) != false` `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator `k` in the range `[i, last)`, `f(*k) == false` `INVOKE(f, INVOKE(proj, *k)) == false`. The relative order of the elements in both groups is preserved. If the execution policy is of type `parallel_task_policy` the algorithm returns a future<> referring to this iterator.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj>
std::pair<FwdIter2, FwdIter3> partition_copy(FwdIter1 first, FwdIter1 last, FwdIter2 dest_true, FwdIter3 dest_false, Pred &&pred, Proj &&proj)
```

Copies the elements in the range, defined by `[first, last)`, to two different ranges depending on the value returned by the predicate `pred`. The elements, that satisfy the predicate `pred` are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.

The assignments in the parallel `partition_copy` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `f`.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition\_copy* algorithm returns *std::pair<OutIter1, OutIter2>*. The *partition\_copy* algorithm returns the pair of the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj>
util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter2, FwdIter3>> partition_copy(ExPolicy
&&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2
dest_true,
FwdIter3
dest_false, Pred
&&pred, Proj
&&proj)
```

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred*, are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition\_copy* algorithm returns a *hpx::future<std::pair<OutIter1, OutIter2>>* if the execution policy is of type *parallel\_task\_policy* and returns *std::pair<OutIter1, OutIter2>* otherwise. The *partition\_copy* algorithm returns the pair of the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

## hpx/parallel/algorithms/reduce.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename T, typename F>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T
init, F &&f)
```

Returns GENERALIZED\_SUM(f, init, \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *f*.

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init)
```

Returns GENERALIZED\_SUM(+, init, \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity: O(*last - first*) applications of the operator+().

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
  - b1, ..., bN may be any permutation of a1, ..., aN and
  - 1 < K+1 = M <= N.

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

**Returns** The *reduce* algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator`+( )`) over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(ExPolicy
&&policy,
FwdIter
first,
FwdIter
last)
```

Returns GENERALIZED\_SUM(+, T(), \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the operator`+( )`.

---

---

**Note:** The type of the initial value (and the result type) `T` is determined from the `value_type` of the used `FwdIter`.

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *reduce* algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns T otherwise (where T is the `value_type` of `FwdIter`). The *reduce* algorithm returns the result of the generalized sum (applying operator`+`()) over the elements given by the input range [first, last).

## hpx/parallel/algorithms/reduce\_by\_key.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parallel**

### Functions

```
template<typename ExPolicy, typename RanIter, typename RanIter2, typename FwdIter1,
         typename FwdIter2, typename Compare = std::equal_to<typename
std::iterator_traits<RanIter>::value_type>, typename Func = std::plus<typename
std::iterator_traits<RanIter2>::value_type>>
```

```
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type reduce_by_key(ExPolicy
    &&policy,
    Ran-
    Iter
    key_first,
    Ran-
    Iter
    key_last,
    Ran-
    Iter2
    val-
    ues_first,
    FwdIter1
    keys_output,
    FwdIter2
    val-
    ues_output,
    Com-
    pare
    &&comp
    =
    Com-
    pare(),
    Func
    &&func
    =
    Func())
```

Reduce by Key performs an inclusive scan reduction operation on elements supplied in key/value pairs. The algorithm produces a single output value for each set of equal consecutive keys in [key\_first, key\_last). the value being the GENERALIZED\_NONCOMMUTATIVE\_SUM(op, init, \*first, ..., \*(first + (i - result))). for the run of consecutive matching keys. The number of keys supplied must match the number of values.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RanIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **RanIter2** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **FwdIter1** – The type of the iterator representing the destination key range (deduced).

This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the iterator representing the destination value range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Compare** – The type of the optional function/function object to use to compare keys (deduced). Assumed to be std::equal\_to otherwise.
- **Func** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **key\_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key\_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **values\_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to.
- **keys\_output** – Refers to the start output location for the keys produced by the algorithm.
- **values\_output** – Refers to the start output location for the values produced by the algorithm.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **func** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

**Returns** The *reduce\_by\_key* algorithm returns a *hpx::future<pair<Iter1,Iter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *pair<Iter1,Iter2>* otherwise.

namespace **v1**

## hpx/parallel/algorithms/remove.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename FwdIter, typename T>
FwdIter remove(FwdIter first, FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the operator==().

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

**Returns** The *remove* algorithm returns a *FwdIter*. The *remove* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type remove(ExPolicy &&policy, FwdIter first, FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the operator==().

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

**Returns** The *remove* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *remove* algorithm returns the iterator to the new end of the range.

```
template<typename FwdIter, typename Pred>
FwdIter remove_if(FwdIter first, FwdIter last, Pred &&pred)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true.

The assignments in the parallel *remove\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *remove\_if* algorithm returns a *FwdIter*. The *remove\_if* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename Pred>
util::detail::algorithm_result<ExPolicy, FwdIter>::type remove_if(ExPolicy &&policy, FwdIter first,
                                                               FwdIter last, Pred &&pred)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true.

The assignments in the parallel *remove\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *remove\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *remove\_if* algorithm returns the iterator to the new end of the range.

## hpx/parallel/algorithms/remove\_copy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename OutIter, typename T>
FwdIter remove_copy(InIter first, InIter last, OutIter dest, T const &value)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator *it* in the range [first,last) for which the following corresponding conditions do not hold: *\*it == value*

The assignments in the parallel *remove\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type that the result of dereferencing FwdIter1 is compared to.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **val** – Value to be removed.

**Returns** The *remove\_copy* algorithm returns an *OutIter*. The *remove\_copy* algorithm returns the iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
FwdIter remove_copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T const &val)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator *it* in the range [first,last) for which the following corresponding conditions do not hold: *\*it == value*

The assignments in the parallel *remove\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type that the result of dereferencing FwdIter1 is compared to.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **val** – Value to be removed.

**Returns** The *remove\_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *remove\_copy* algorithm returns the iterator to the element past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **Pred**>  
FwdIter **remove\_copy\_if**(*InIter* first, *InIter* last, *OutIter* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator *it* in the range [first, last) for which the following corresponding conditions do not hold: *INVOKED(pred, \*it) != false*.

The assignments in the parallel *remove\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced).
- **Pred** – The type of the function/function object to use (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *remove\_copy\_if* algorithm returns an *OutIter*. The *remove\_copy\_if* algorithm returns the iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
FwdIter remove_copy_if(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator *it* in the range [first, last) for which the following corresponding conditions do not hold: *INVOKE(pred, \*it) != false*.

The assignments in the parallel *remove\_copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_copy\_if* requires *Pred* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *remove\_copy\_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *remove\_copy\_if* algorithm returns the iterator to the element past the last element copied.

## hpx/parallel/algorithms/replace.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename T>
void replace(InIter first, InIter last, T const &old_value, T const &new_value)
    Replaces all elements satisfying specific criteria with new_value in the range [first, last).
    Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the
            following corresponding conditions hold: *it == old_value
```

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the old and new values to replace (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace* algorithm returns a *void*.

```
template<typename ExPolicy, typename FwdIter, typename T>
parallel::util::detail::algorithm_result<ExPolicy, void>::type replace(ExPolicy &&policy, FwdIter first,
                                                               FwdIter last, T const &old_value, T
                                                               const &new_value)
```

Replaces all elements satisfying specific criteria with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator *it* in the range [first, last) with *new\_value*, when the following corresponding conditions hold: *\*it == old\_value*

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the old and new values to replace (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename Iter, typename Pred, typename T>
void replace_if(Iter first, Iter last, Pred &&pred, T const &new_value)
```

Replaces all elements satisfying specific criteria (for which predicate *f* returns true) with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator *it* in the range [first, last) with *new\_value*, when the following corresponding conditions hold: *(INVOKE(f, \*it) != false*

The assignments in the parallel *replace\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace\_if* algorithm returns *void*.

```
template<typename ExPolicy, typename FwdIter, typename Pred, typename T>
parallel::util::detail::algorithm_result<ExPolicy, void>::type replace_if(ExPolicy &&policy, FwdIter first,
                                                               FwdIter last, Pred &&pred, T
                                                               const &new_value)
```

Replaces all elements satisfying specific criteria (for which predicate *f* returns true) with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator *it* in the range [first, last) with *new\_value*, when the following corresponding conditions hold: *(INVOKE(f, \*it) != false*

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace\_if* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename InIter, typename OutIter, typename T>
OutIter replace_copy(InIter first, InIter last, OutIter dest, T const &old_value, T const &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either *new\_value* or \*(first + (it - result)) depending on whether the following corresponding condition holds: \*(first + (i - result)) == *old\_value*

The assignments in the parallel *replace\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate. of the algorithm may be parallelized and the manner in which it executes the assignments.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the old and new values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace\_copy* algorithm returns an *OutIter*. The *replace\_copy* algorithm returns the Iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type replace_copy(ExPolicy &&policy,
FwdIter1 first, FwdIter1
last, FwdIter2 dest, T const
&old_value, T const
&new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either *new\_value* or \*(first + (it - result)) depending on whether the following corresponding condition holds: \*(first + (i - result)) == *old\_value*

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the old and new values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace\_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *replace\_copy* algorithm returns the Iterator to the element past the last element copied.

```
template<typename InIter, typename OutIter, typename Pred, typename T>
OutIter replace_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred, T const &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range [result, result + (last - first)) either *new\_value* or \*(first + (it - result)) depending on whether the following corresponding condition holds: *(INVOKE(f, \*(first + (i - result))) != false*

The assignments in the parallel *replace\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The `replace_copy_if` algorithm returns an `OutIter`. The `replace_copy_if` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred, typename T>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type replace_copy_if(ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last, FwdIter2
dest, Pred &&pred, T
const &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

**Effects:** Assigns to every iterator *it* in the range [*result*, *result* + (last - first)) either *new\_value* or \*(*first* + (*i* - *result*)) depending on whether the following corresponding condition holds: `INVOKE(f, *(first + (i - result))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

**Returns** The *replace\_copy\_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *replace\_copy\_if* algorithm returns the iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/reverse.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename BidirIter>
void reverse(BidirIter first, BidirIter last)
```

Reverses the order of the elements in the range [first, last). Behaves as if applying *std::iter\_swap* to every pair of iterators *first+i*, *(last-i)-1* for each non-negative *i < (last-first)/2*.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

**Template Parameters `BidirIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *reverse* algorithm returns a *void*.

```
template<typename ExPolicy, typename BidirIter>
parallel::util::detail::algorithm_result<ExPolicy, void>::type reverse(ExPolicy &&policy, BidirIter first,
BidirIter last)
```

Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter\_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *reverse* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename BidirIter, typename OutIter>
OutIter reverse_copy(BidirIter first, BidirIter last, OutIter dest)
```

Copies the elements from the range [first, last) to another range beginning at dest\_first in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment \*(dest\_first + (last - first) - 1 - i) = \*(first + i) once for each non-negative i < (last - first). If the source and destination ranges (that is, [first, last) and [dest\_first, dest\_first+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the begin of the destination range.

**Returns** The *reverse\_copy* algorithm returns an *OutIter*. The *reverse\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename BidirIter, typename FwdIter>
util::detail::algorithm_result<ExPolicy, FwdIter>::type reverse_copy(ExPolicy &&policy, BidirIter first,
                                                               BidirIter last, FwdIter dest_first)
```

Copies the elements from the range [first, last) to another range beginning at dest\_first in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment \*(dest\_first + (last - first) - 1 - i) = \*(first + i) once for each non-negative i < (last - first). If the source and destination ranges (that is, [first, last) and [dest\_first, dest\_first+(last-first)) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the begin of the destination range.

**Returns** The *reverse\_copy* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *reverse\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/rotate.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter>
FwdIter rotate(FwdIter first, FwdIter new_first, FwdIter last)
```

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element *new\_first* becomes the first element of the new range and *new\_first - 1* becomes the last element.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

**Template Parameters `FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to. The assignments in the parallel *rotate* algorithm execute in sequential order in the calling thread.

**Returns** The *rotate* algorithm returns a `FwdIter`. The *rotate* algorithm returns the iterator to the new location of the element pointed by `first`, equal to `first + (last - new_first)`.

```
template<typename ExPolicy, typename FwdIter>
```

```
util::detail::algorithm_result<ExPolicy, FwdIter>::type rotate(ExPolicy &&policy, FwdIter first, FwdIter  
new_first, FwdIter last)
```

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new\_first becomes the first element of the new range and new\_first - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *rotate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *rotate* algorithm returns the iterator equal to *first* + (*last* - *new\_first*).

```
template<typename FwdIter, typename OutIter>  
OutIter rotate_copy(FwdIter first, FwdIter new_first, FwdIter last, OutIter dest_first)
```

Copies the elements from the range [first, last), to another range beginning at *dest\_first* in such a way, that the element *new\_first* becomes the first element of the new range and *new\_first* - 1 becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

## Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **OutIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an output iterator.

## Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_first** – Refers to the begin of the destination range.

**Returns** The *rotate\_copy* algorithm returns a output iterator, The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type rotate_copy(ExPolicy &&policy, FwdIter1 first,
                                                               FwdIter1 new_first, FwdIter1 last,
                                                               FwdIter2 dest_first)
```

Copies the elements from the range [first, last), to another range beginning at *dest\_first* in such a way, that the element *new\_first* becomes the first element of the new range and *new\_first* - 1 becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm execute in sequential order in the calling thread.

The assignments in the parallel *rotate\_copy* algorithm execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_first** – Refers to the begin of the destination range.

**Returns** The *rotate\_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

## hpx/parallel/algorithms/search.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter search(FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

<b>bool pred(const Type1 &amp;a, const Type2 &amp;b);</b>
---

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

**Returns** The *search* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s\_first, s\_last) in range [first, last). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

```
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search(ExPolicy &&policy, FwdIter first, FwdIter
last, FwdIter2 s_first, FwdIter2 s_last, Pred
&&op = Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

**Returns** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence  $[s_{\text{first}}, s_{\text{last}})$  in range  $[\text{first}, \text{last})$ . If the length of the subsequence  $[s_{\text{first}}, s_{\text{last}})$  is greater than the length of the range  $[\text{first}, \text{last})$ , `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```
template<typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter search_n(FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range  $[\text{first}, \text{last})$  for any elements in the range  $[s_{\text{first}}, s_{\text{last}})$ . Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S = \text{distance}(s_{\text{first}}, s_{\text{last}})$  and  $N = \text{count}$ .

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `search_n` algorithm returns `FwdIter`. The `search_n` algorithm returns an iterator to the beginning of the last subsequence  $[s_{\text{first}}, s_{\text{last}}]$  in range  $[\text{first}, \text{first}+\text{count}]$ . If the length of the subsequence  $[s_{\text{first}}, s_{\text{last}}]$  is greater than the length of the range  $[\text{first}, \text{first}+\text{count}]$ , `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search_n(ExPolicy &&policy, FwdIter first,
                                                               std::size_t count, FwdIter2 s_first,
                                                               FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range  $[\text{first}, \text{last}]$  for any elements in the range  $[s_{\text{first}}, s_{\text{last}}]$ . Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S = \text{distance}(s_{\text{first}}, s_{\text{last}})$  and  $N = \text{count}$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

**Returns** The `search_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search_n` algorithm returns an iterator to the beginning of the last subsequence  $[s_{\text{first}}, s_{\text{last}})$  in range  $[first, first+count]$ . If the length of the subsequence  $[s_{\text{first}}, s_{\text{last}})$  is greater than the length of the range  $[first, first+count]$ , `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

## hpx/parallel/algorithms/set\_difference.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type set_difference(ExPolicy &&policy,
FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&cop = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in the range  $[first1, last1)$  and not present in the range  $[first2, last2)$ . This algorithm expects both input ranges to be sorted with the given binary predicate  $f$ .

Equivalent elements are treated individually, that is, if some element is found  $m$  times in  $[first1, last1)$  and  $n$  times in  $[first2, last2)$ , it will be copied to `dest` exactly `std::max(m-n, 0)` times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (for `sequenced_task_policy`).

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

**Returns** The *set\_difference* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The *set\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/set\_intersection.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename  
Pred = detail::less>  
util::detail::algorithm_result<ExPolicy, FwdIter3>::type set_intersection(ExPolicy &&policy, FwdIter1  
first1, FwdIter1 last1, FwdIter2  
first2, FwdIter2 last2, FwdIter3  
dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate f.

If some element is found  $m$  times in [first1, last1) and  $n$  times in [first2, last2), the first  $\text{std}::\text{min}(m, n)$  elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

**Returns** The *set\_intersection* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The *set\_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/set\_symmetric\_difference.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type set_symmetric_difference(ExPolicy
&&policy,
FwdIter1 first1,
FwdIter1 last1,
FwdIter2 first2,
FwdIter2 last2,
FwdIter3 dest,
Pred &&op =
Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges [*first1*, *last1*] and [*first2*, *last2*], but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in [*first1*, *last1*] and *n* times in [*first2*, *last2*], it will be copied to *dest* exactly  $\text{std::abs}(m-n)$  times. If *m>n*, then the last *m-n* of those elements are copied from [*first1*,*last1*], otherwise the last *n-m* elements are copied from [*first2*,*last2*]. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

**Returns** The `set_symmetric_difference` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/set\_union.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type set_union(ExPolicy &&policy, FwdIter1
first1, FwdIter1 last1, FwdIter2
first2, FwdIter2 last2, FwdIter3
dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in one or both sorted ranges `[first1, last1]` and `[first2, last2]`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found  $m$  times in `[first1, last1]` and  $n$  times in `[first2, last2]`, then all  $m$  elements will be copied from `[first1, last1]` to `dest`, preserving order, and then exactly `std::max(n-m, 0)` elements will be copied from `[first2, last2]` to `dest`, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (for `sequenced_task_policy`).

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

**Returns** The *set\_union* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The *set\_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## `hpx/parallel/algorithms/shift_left.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

```
template<typename FwdIter, typename Size>
FwdIter shift_left(FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift\_left* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_left* algorithm returns *FwdIter*. The *shift\_left* algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename FwdIter, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_left(ExPolicy &&policy, FwdIter first,
FwdIter last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_left* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *shift\_left* algorithm returns an iterator to the end of the resulting range.

## hpx/parallel/algorithms/shift\_right.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Size>
FwdIter shift_right(FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift\_right* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_right* algorithm returns *FwdIter*. The *shift\_right* algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename FwdIter, typename SizeExPolicy, FwdIter> shift_right(ExPolicy &&policy, FwdIter first,
FwdIter last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- $n + i$ .

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_right* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *shift\_right* algorithm returns an iterator to the end of the resulting range.

## hpx/parallel/algorithms/sort.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandomIt>
void sort(RandomIt first, RandomIt last)
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object `comp` (defaults to using operator`<()`).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKED(comp, INVOKED(proj, *(i + n)), INVOKED(proj, *i)) == false`.

The assignments in the parallel *sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

**Template Parameters** `RandomIt` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *sort* algorithm does not return anything.

```
template<typename ExPolicy, typename RandomIt>
```

---

`util::detail::algorithm_result<ExPolicy>::type sort(ExPolicy &&policy, RandomIt first, RandomIt last)`

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `sort` algorithm returns a `hpx::future<void>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename RandomIt, typename Comp, typename Proj>
void sort(RandomIt first, RandomIt last, Comp &&comp, Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel `sort` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.

---

### Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *sort* algorithm returns nothing.

```
template<typename ExPolicy, typename RandomIt, typename Comp, typename Proj>
parallel::util::detail::algorithm_result<ExPolicy>::type sort(ExPolicy &&policy, RandomIt first, RandomIt
last, Comp &&comp, Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and INVOKE(*comp*, INVOKE(*proj*, \*(*i + n*)), INVOKE(*proj*, \**i*)) == false.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `sort` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns nothing otherwise.

## hpx/parallel/algorithms/sort\_by\_key.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **parallel**

### Typedefs

```
template<typename KeyIter, typename ValueIter>
using sort_by_key_result = std::pair<KeyIter, ValueIter>
```

### Functions

```
template<typename ExPolicy, typename KeyIter, typename ValueIter, typename Compare =
detail::less>
```

```
util::detail::algorithm_result_t<ExPolicy, sort_by_key_result<KeyIter, ValueIter>> sort_by_key(ExPolicy  
    &&policy,  
    KeyIter  
    key_first,  
    KeyIter  
    key_last,  
    Val-  
    ueIter  
    value_first,  
    Com-  
    pare  
    &&comp  
    =  
    Com-  
    pare())
```

Sorts one range of data using keys supplied in another range. The key elements in the range [key\_first, key\_last) are sorted in ascending order with the corresponding elements in the value range moved to follow the sorted order. The algorithm is not stable, the order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and *INVOKE(comp, INVOKE(proj, \*(i + n)), INVOKE(proj, \*i)) == false*.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **KeyIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **ValueIter** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **key\_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key\_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.

- **value\_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match [key\_first, key\_last)
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

**Returns** The *sort\_by-key* algorithm returns a `hpx::future<sort_by_key_result<KeyIter, ValueIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns *otherwise*. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

namespace **v1**

## **hpx/parallel/algorithms/stable\_sort.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandomIt>
void stable_sort(RandomIt first, RandomIt last)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that  $i + n$  is a valid iterator pointing to an element of the sequence, and  $\text{(INVOKE}(\text{comp}, \text{(INVOKE}(\text{proj}, *(i + n)), \text{(INVOKE}(\text{proj}, *i))) == \text{false})$ .

The assignments in the parallel *stable\_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std::distance(first, last)}$  comparisons.

---

**Template Parameters `RandomIt`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *stable\_sort* algorithm does not return anything.

```
template<typename ExPolicy, typename RandomIt>
```

```
util::detail::algorithm_result<ExPolicy>::type stable_sort(ExPolicy &&policy, RandomIt first, RandomIt last)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `stable_sort` algorithm returns a `hpx::future<void>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename RandomIt, typename Comp, typename Proj>
void stable_sort(RandomIt first, RandomIt last, Comp &&comp, Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel `stable_sort` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.

---

### Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *stable\_sort* algorithm returns nothing.

```
template<typename ExPolicy, typename RandomIt, typename Comp, typename Proj>
parallel::util::detail::algorithm_result<ExPolicy>::type stable_sort(ExPolicy &&policy, RandomIt first,
                                                               RandomIt last, Comp &&comp, Proj
                                                               &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and INVOKE(*comp*, INVOKE(*proj*, \*(*i + n*)), INVOKE(*proj*, \**i*)) == false.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `stable_sort` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns nothing otherwise.

```

namespace **parallel**

namespace **v1**

## **hpx/parallel/algorithms/swap\_ranges.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter1, typename FwdIter2>
FwdIter2 swap_ranges(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2)
```

Exchanges elements between range [first1, last1) and another range starting at first2.

The swap operations in the parallel *swap\_ranges* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*

---

### Template Parameters

- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

**Returns** The *swap\_ranges* algorithm returns *FwdIter2*. The *swap\_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type swap_ranges(ExPolicy &&policy,
FwdIter1 first1, FwdIter1
last1, FwdIter2 first2)
```

Exchanges elements between range [first1, last1) and another range starting at first2.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.
- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.

- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

**Returns** The *swap\_ranges* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *swap\_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

## hpx/parallel/algorithms/transform.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type transform(ExPolicy
    &&policy,
    FwdIter1
    first,
    FwdIter1
    last,
    FwdIter2
    dest, F
    &&f)
```

Applies the given function *f* to the range [first, last) and stores the result in another range, beginning at dest.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *last - first* applications of *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`.

**Returns** The `transform` algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `parallel_task_policy` and returns `in_out_result<FwdIter1, FwdIter2>` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F>
util::detail::algorithm_result<ExPolicy, util::in_in_out_result<FwdIter1, FwdIter2, FwdIter3>>::type transform(ExPolicy
    &&policy,
    FwdIter1
    first1,
    FwdIter1
    last1,
    FwdIter2
    first2,
    FwdIter2
    dest,
    F
    &&f)
```

Applies the given function  $f$  to pairs of elements from two ranges: one defined by  $[first1, last1)$  and the other beginning at  $first2$ , and stores the result in another range, beginning at  $dest$ .

The invocations of  $f$  in the parallel `transform` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The invocations of  $f$  in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $last - first$  applications of  $f$

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **FwdIter1** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last].This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const&**. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively. The type *Ret* must be such that an object of type *FwdIter3* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *transform* algorithm returns a *hpx::future<in\_in\_out\_result<FwdIter1, FwdIter2, FwdIter3> >* if the execution policy is of type *parallel\_task\_policy* and returns *in\_in\_out\_result<FwdIter1, FwdIter2, FwdIter3>* otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/transform\_exclusive\_scan.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename InIter, typename OutIter, typename T, typename BinOp, typename UnOp>
OutIter transform_exclusive_scan(InIter first, InIter last, OutIter dest, T init, BinOp &&binary_op,
UnOp &&unary_op)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\* $(first + (i - result) - 1)$ )).

The reduce operations in the parallel *transform\_exclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_exclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,  $a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
  - $\text{op}(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_1, \dots, a_K), \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_M, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by  $[first, last)$ . This is a unary predicate. The signature of this predicate should be equivalent to:

R **fun**(**const** Type &*a*);

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

- **`init`** – The initial value for the generalized sum.
- **`op`** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `transform_exclusive_scan` algorithm returns a returns `OutIter`. The `transform_exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename BinOp,  
typename UnOp>  
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_exclusive_scan(ExPolicy  
    &&policy,  
    FwdIter1  
    first,  
    FwdIter1  
    last,  
    FwdIter2  
    dest, T init,  
    BinOp  
    &&bi-  
    nary_op,  
    UnOp  
    &&unary_op)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*( $first + (i - result) - 1$ ))).

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of `transform_exclusive_scan` may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates `op` and `conv`.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1
  - op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, ..., aN)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The *transform\_exclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The *transform\_exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/transform\_inclusive\_scan.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename OutIter, typename BinOp, typename UnOp>
OutIter transform_inclusive_scan(InIter first, InIter last, OutIter dest, BinOp &&binary_op, UnOp
&&unary_op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(op, conv(\*first), ..., conv(\*(first + (i - result))))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a<sub>1</sub>, ..., a<sub>N</sub>) is defined as:

- a<sub>1</sub> when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a<sub>1</sub>, ..., a<sub>K</sub>), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a<sub>M</sub>, ..., a<sub>N</sub>)) where 1 < K+1 = M <= N.
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

**Returns** The `transform_inclusive_scan` algorithm returns a `OutIter`. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy
    &&policy,
    FwdIter1
    first,
    FwdIter1
    last,
    FwdIter2
    dest, BinOp
    &&bi-
    nary_op,
    UnOp
    &&&unary_op)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM( $op, conv(*first), \dots, conv(*(first + (i - result)))$ ).

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,      *a*1,      ... ,      *a*K),      GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*M, ..., *a*N)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

**Returns** The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename BinOp, typename UnOp, typename T>
OutIter transform_inclusive_scan(InIter first, InIter last, OutIter dest, BinOp &&binary_op, UnOp
&&unary_op, T init)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), \dots, conv(*first + (i - result)))`.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The difference between `inclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the  $i$ th input element in the  $i$ th sum. `op` is not mathematically associative, the behavior of `transform_inclusive_scan` may be non-deterministic.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate `op`.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, \dots, aN)` is defined as:

- $a1$  when  $N$  is 1
  - $op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, \dots, aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, \dots, aN))$  where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

- **init** – The initial value for the generalized sum.

**Returns** The `transform_inclusive_scan` algorithm returns a `OutIter`. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**, typename **T**>

```
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy
&&policy,
FwdIter1
first,
FwdIter1
last,
FwdIter2
dest, BinOp
&&bi-
nary_op,
UnOp
&&unary_op,
T init)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(`op`, `init`, `conv(*first, ..., conv(*first + (i - result)))`).

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum. *op* is not mathematically associative, the behavior of *transform\_inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a<sub>1</sub>, ..., a<sub>N</sub>) is defined as:

- a<sub>1</sub> when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a<sub>1</sub>, ..., a<sub>K</sub>), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a<sub>M</sub>, ..., a<sub>N</sub>)) where 1 < K+1 = M <= N.
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

- **init** – The initial value for the generalized sum.

**Returns** The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/transform\_reduce.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

```
template<typename ExPolicy, typename FwdIter, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, FwdIter first,
                                                               FwdIter last, T init, Reduce &&red_op,
                                                               Convert &&conv_op)
```

Returns `GENERALIZED_SUM(red_op, init, conv_op(*first), ..., conv_op(*(first + (last - first) - 1)))`.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `transform_reduce` and `accumulate` is that the behavior of `transform_reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates `red_op` and `conv_op`.

---

---

**Note:** `GENERALIZED_SUM(op, a1, ..., aN)` is defined as follows:

- $a_1$  when  $N$  is 1
  - $op(GENERALIZED\_SUM(op, b_1, \dots, b_K), GENERALIZED\_SUM(op, b_M, \dots, b_N))$ , where:
    - $b_1, \dots, b_N$  may be any permutation of  $a_1, \dots, a_N$  and
    - $1 < K+1 = M \leq N$ .
-

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv\_op* can be implicitly converted to any of those types.

**Returns** The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel\_task\_policy* and returns *T* otherwise. The *transform\_reduce* algorithm returns the result of the generalized sum over the values returned from *conv\_op* when applied to the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, FwdIter1 first1,
                                                               FwdIter1 last1, FwdIter2 first2, T init)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(*last - first*) applications of the predicate *op2*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

**Returns** The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Reduce,
typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, FwdIter1 first1,
                                                               FwdIter1 last1, FwdIter2 first2, T init,
                                                               Reduce &&red_op, Convert
                                                               &&conv_op)
```

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate  $op2$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of  $op2$ . This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Ret` must be such that it can be implicitly converted to a type of `T`.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Ret` must be such that it can be implicitly converted to an object for the second argument type of  $op1$ .

**Returns** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise.

## hpx/parallel/algorithms/transform\_reduce\_binary.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## hpx/parallel/algorithms/uninitialized\_copy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename FwdIter>
FwdIter uninitialized_copy(InIter first, InIter last, FwdIter dest)
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_copy* algorithm returns *FwdIter*. The *uninitialized\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type uninitialized_copy(ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest)
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_copy* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **Size**, typename **FwdIter**>  
*FwdIter uninitialized\_copy\_n*(*InIter* first, *Size* count, *FwdIter* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count > 0*, no assignments otherwise.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_copy\_n* algorithm returns a returns *FwdIter2*. The *uninitialized\_copy\_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type uninitialized_copy_n(ExPolicy
&&policy,
FwdIter1 first,
Size count,
FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_copy\_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_copy\_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/algorithms/uninitialized\_default\_construct.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter>
void uninitialized_default_construct(FwdIter first, FwdIter last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters `FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *uninitialized\_default\_construct* algorithm returns nothing

```
template<typename ExPolicy, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy>::type uninitialized_default_construct(ExPolicy
&&policy,
FwdIter first,
FwdIter last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *uninitialized\_default\_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

template<typename **FwdIter**, typename **Size**>  
**FwdIter** **uninitialized\_default\_construct\_n**(*FwdIter* *first*, *Size* *count*)

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range [*first*, *first* + *count*] by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_default\_construct\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_default\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_default_construct_n(ExPolicy
    &&policy,
    FwdIter
    first,
    Size
    count)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_default\_construct\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_default\_construct\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_default\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

## `hpx/parallel/algorithms/uninitialized_fill.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

```
template<typename FwdIter, typename T>
void uninitialized_fill(FwdIter first, FwdIter last, T const &value)
```

Copies the given `value` to an uninitialized memory area, defined by the range `[first, last]`. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_fill` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between `first` and `last`

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The `uninitialized_fill` algorithm returns nothing

```
template<typename ExPolicy, typename FwdIter, typename T>
parallel::util::detail::algorithm_result<ExPolicy>::type uninitialized_fill(ExPolicy &&policy, FwdIter
first, FwdIter last, T const &value)
```

Copies the given `value` to an uninitialized memory area, defined by the range `[first, last]`. If an exception is thrown during the initialization, the function has no effects.

The initializations in the parallel `uninitialized_fill` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The initializations in the parallel `uninitialized_fill` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between `first` and `last`

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename FwdIter, typename Size, typename T>
FwdIter uninitialized_n(FwdIter first, Size count, T const &value)
```

Copies the given *value* value to the first *count* elements in an uninitialized memory area beginning at *first*. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_fill\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_fill\_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
```

---

```
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_fill_n(ExPolicy
&&policy,
FwdIter first, Size
count, T const
&value)
```

Copies the given *value* value to the first *count* elements in an uninitialized memory area beginning at *first*. If an exception is thrown during the initialization, the function has no effects.

The initializations in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill\_n* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_fill\_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

## hpx/parallel/algorithms/uninitialized\_move.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename InIter, typename FwdIter>
FwdIter uninitialized_move(InIter first, InIter last, FwdIter dest)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_move* algorithm returns *FwdIter*. The *uninitialized\_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type uninitialized_move(ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_move* algorithm returns a `hpx::future<FwdIter2>`, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename InIter, typename Size, typename FwdIter>
FwdIter uninitialized_move_n(InIter first, Size count, FwdIter dest)
```

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* movements, if *count* > 0, no move operations otherwise.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_move\_n* algorithm returns a returns *FwdIter2*. The *uninitialized\_move\_n* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2ExPolicy, FwdIter2>::type uninitialized_move_n(ExPolicy
&&policy,
FwdIter1 first,
Size count,
FwdIter2 dest)
```

Moves the elements in the range [*first*, *first* + *count*), starting from *first* and proceeding to *first* + *count* - 1., to another range beginning at *dest*. If an exception is thrown during the initialization, some objects in [*first*, *first* + *count*) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* movements, if *count* > 0, no move operations otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized\_move\_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_move\_n* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

## hpx/parallel/algorithms/uninitialized\_value\_construct.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter>
void uninitialized_value_construct(FwdIter first, FwdIter last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters `FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *uninitialized\_value\_construct* algorithm returns nothing

```
template<typename ExPolicy, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy>::type uninitialized_value_construct(ExPolicy
&&policy,
FwdIter first,
FwdIter last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *uninitialized\_value\_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename FwdIter, typename Size>
FwdIter uninitialized_value_construct_n(FwdIter first, Size count)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_value\_construct\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_value\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Size>
```

---

```
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_value_construct_n(ExPolicy
    &&policy,
    FwdIter
    first,
    Size
    count)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_value\_construct\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_value\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

## hpx/parallel/algorithms/unique.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename FwdIter>
FwdIter unique(FwdIter first, FwdIter last)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments.

---

**Template Parameters `FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *unique* algorithm returns *FwdIter*. The *unique* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type unique(ExPolicy &&policy, FwdIter first,
FwdIter last)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *unique* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *unique* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj>
FwdIter unique(FwdIter first, FwdIter last, Pred &&pred, Proj &&proj)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique* algorithm returns *FwdIter*. The *unique* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj>
```

```
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type unique(ExPolicy &&policy, FwdIter first,
FwdIter last, Pred &&pred, Proj
&&proj)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *unique* algorithm returns the iterator to the new end of the range.

---

```
template<typename InIter, typename OutIter>
OutIter unique_copy(InIter first, InIter last, OutIter dest)
```

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

The assignments in the parallel *unique\_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *unique\_copy* algorithm returns a returns *OutIter*. The *unique\_copy* algorithm returns the destination iterator to the end of the *dest* range.

---

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type unique_copy(ExPolicy &&policy,
FwdIter1 first, FwdIter1 last,
FwdIter2 dest)
```

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

The assignments in the parallel *unique\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *unique\_copy* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *unique\_copy* algorithm returns the pair of the source iterator to *last*, and the destination iterator to the end of the *dest* range.

```
template<typename InIter, typename OutIter, typename Pred, typename Proj>
OutIter unique_copy(InIter first, InIter last, OutIter dest, Pred &&pred, Proj &&proj)
```

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

The assignments in the parallel *unique\_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique\_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique\_copy* algorithm returns a returns *OutIter*. The *unique\_copy* algorithm returns the destination iterator to the end of the *dest* range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred, typename Proj>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type unique_copy(ExPolicy &&policy,
FwdIter1 first, FwdIter1 last,
FwdIter2 dest, Pred
&&pred, Proj &&proj)
```

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

The assignments in the parallel *unique\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique\_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique\_copy* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *unique\_copy* algorithm returns the pair of the source iterator to *last*, and the destination iterator to the end of the *dest* range.

## hpx/parallel/container\_algorithms/adjacent\_difference.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter1, typename FwdIter2, typename Sent>
FwdIter2 adjacent_difference(FwdIter1 first, Sent last, FwdIter2 dest)
```

Searches the range [first, last) for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *adjacent\_difference* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename Rng, typename FwdIter2>
FwdIter2 adjacent_difference(Rng &&rng, FwdIter2 dest)
```

Searches the *rng* for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

---

#### Template Parameters

- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *adjacent\_difference* algorithm returns an iterator to the first of the identical elements.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy
&&policy,
FwdIter1
first, Sent
last,
FwdIter2
dest)
```

Searches the range [*first*, *last*] for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *adjacent\_difference* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename ExPolicy, typename Rng, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy
    &&policy,
    Rng
    &&rng,
    FwdIter2
    dest)
```

Searches the *rng* for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *adjacent\_difference* algorithm returns an iterator to the first of the identical elements.

```
template<typename FwdIter1, typename Sent, typename FwdIter2, typename Op>
FwdIter2 adjacent_difference(FwdIter1 first, Sent last, FwdIter2 dest, Op &&op)
```

Searches the range [first, last) for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent\_difference* requires *Op* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`. The types `Type1` and `Type2` must be such that an object of type `iterator_traits<InputIt>::value_type` can be implicitly converted to both of them. The type `Ret` must be such that an object of type `OutputIt` can be dereferenced and assigned a value of type `Ret`.

**Returns** The `adjacent_difference` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

```
template<typename Rng, typename FwdIter2, typename Op>
FwdIter2 adjacent_difference(Rng &&rng, FwdIter2 dest, Op &&op)
```

Searches the `rng` for two consecutive identical elements.

#### Template Parameters

- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `adjacent_difference` requires `Op` to meet the requirements of `CopyConstructible`.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`. The types `Type1` and `Type2` must be such that an object of type `iterator_traits<InputIt>::value_type` can be implicitly converted to both of them. The type `Ret` must be such that an object of type `OutputIt` can be dereferenced and assigned a value of type `Ret`.?

**Returns** The `adjacent_difference` algorithm returns an iterator to the first of the identical elements.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Op>
```

```
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy
&&policy,
FwdIter1
first, Sent
last,
FwdIter2
dest, Op
&&op)
```

Searches the range [first, last) for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of  $(\text{result} - \text{first}) + 1$  and  $(\text{last} - \text{first}) - 1$  application of the predicate where *result* is the value returned

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent\_difference* requires *Op* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const &**. The types *Type1* and *Type2* must be such that an object of type *iterator\_traits<InputIt>::value\_type* can be implicitly converted to both of them. The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.?

**Returns** The *adjacent\_difference* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename ExPolicy, typename Rng, typename FwdIter2, typename Op>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy
    &&policy,
    Rng
    &&rng,
    FwdIter2
    dest, Op
    &&op)
```

Searches the *rng* for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of  $(\text{result} - \text{first}) + 1$  and  $(\text{last} - \text{first}) - 1$  application of the predicate where *result* is the value returned

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent\_difference* requires *Op* to meet the requirements of *CopyConstructible*.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`. The types *Type1* and *Type2* must be such that an object of type *iterator\_traits<InputIt>::value\_type* can be implicitly converted to both of them. The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *adjacent\_difference* algorithm returns an iterator to the first of the identical elements.

**hpx/parallel/container\_algorithms/adjacent\_find.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

**Functions**

```
template<typename FwdIter, typename Sent, typename Proj = hpx::parallel::util::projection_identity,
         typename Pred = detail::equal_to>
FwdIter adjacent_find(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Searches the range [first, last) for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*
- **Pred** – The type of an optional function/function object to use.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `adjacent_find` algorithm returns an iterator to the first of the identical elements.

If no such elements are found, `last` is returned.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Proj =  
hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>  
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type adjacent_find(ExPolicy &&policy,  
FwdIter first, Sent  
last, Pred &&pred =  
Pred(), Proj &&proj  
= Proj())
```

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate `pred`

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

---

**Note:** Complexity: Exactly the smaller of (`result - first`) + 1 and (`last - first`) - 1 application of the predicate where `result` is the value returned

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of

*CopyConstructible*. This defaults to std::equal\_to<>

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *adjacent\_find* algorithm returns a *hpx::future<InIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *InIter* otherwise. The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename Rng, typename Proj = hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>
hpx::traits::range_traits<Rng>::iterator_type adjacent_find(Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Searches the range *rng* for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of (*result* - std::begin(*rng*)) + 1 and (std::begin(*rng*) - std::end(*rng*)) - 1 applications of the predicate where *result* is the value returned

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*
- **Pred** – The type of an optional function/function object to use.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>
```

`parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type adjacent_find`

Searches the range `rng` for two consecutive identical elements.

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

---

**Note:** Complexity: Exactly the smaller of `(result - std::begin(rng)) + 1` and `(std::begin(rng) - std::end(rng)) - 1` applications of the predicate where `result` is the value returned

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *adjacent\_find* algorithm returns a *hpx::future<InIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *InIter* otherwise. The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

### Functions

```
template<typename ExPolicy, typename Rng, typename F, typename Proj =  
        hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, Rng  
                           &&rng, F &&f, Proj  
                           &&proj = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `none_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =  
hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, Iter  
first, Sent last, F &&f, Proj  
&&proj = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `none_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Rng, typename F, typename Proj = hpx::parallel::util::projection_identity>
bool none_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range *rng*.

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `none_of` algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Iter, typename Sent, typename F, typename Proj =
hpx::parallel::util::projection_identity>
bool none_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

**Note:** Complexity: At most *last - first* applications of the predicate *f*

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential

form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.

- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj =  
    hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type any_of(ExPolicy &&policy, Rng  
    &&rng, F &&f, Proj &&proj  
    = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =
  hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type any_of(ExPolicy &&policy, Iter first,
  Sent last, F &&f, Proj
  &&proj = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename Rng, typename F, typename Proj = hpx::parallel::util::projection_identity>
bool any_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `any_of` algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename Iter, typename Sent, typename F, typename Proj =
hpx::parallel::util::projection_identity>
bool any_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).

- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj =
  hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type all_of(ExPolicy &&policy, Rng
  &&rng, F &&f, Proj &&proj
  = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *all\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =  
hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type all_of(ExPolicy &&policy, Iter first,  
Sent last, F &&f, Proj  
&&proj = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate *f*

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `all_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `all_of` algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Rng, typename F, typename Proj = hpx::parallel::util::projection_identity>
bool all_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `all_of` algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Iter, typename Sent, typename F, typename Proj =
hpx::parallel::util::projection_identity>
bool all_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

**Template Parameters**

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

## hpx/parallel/container\_algorithms/copy.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_result<FwdIter1, FwdIter>>::type copy(ExPolicy
    &&policy,
    FwdIter1
    iter,
    Sent1
    sent,
    FwdIter
    dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy* algorithm returns a *hpx::future<ranges::copy\_result<FwdIter1, FwdIter>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::copy\_result<FwdIter1, FwdIter>* otherwise. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_result<typename hpx::traits::range_traits<Rng>::iterator_type,
```

Copies the elements in the range *rng* to another range beginning at *dest*.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy* algorithm returns a `hpx::future<ranges::copy_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_result<iterator_t<Rng>, FwdIter2>` otherwise. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename Sent1, typename FwdIter>
ranges::copy_result<FwdIter1, FwdIter> copy(FwdIter1 iter, Sent1 sent, FwdIter dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
FwdIter copy(Rng &&rng, FwdIter dest)
```

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_n_result<FwdIter1, FwdIter2>>::type copy_n(ExPolicy &&policy, FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at *dest*.

The assignments in the parallel *copy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy\_n* algorithm returns a *hpx::future<ranges::copy\_n\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::copy\_n\_result<FwdIter1, FwdIter2>* otherwise. The *copy* algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename Size, typename FwdIter2>
ranges::copy_n_result<FwdIter1, FwdIter2> copy_n(FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *copy* algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination

range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter, typename  
Pred, typename Proj = hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_if_result<FwdIter1, FwdIter>>::type copy_if(ExPolicy  
    &&policy,  
    FwdIter1 iter,  
    Sent1 sent,  
    FwdIter dest,  
    Pred &&pred,  
    Proj &&proj  
    =  
    Proj())
```

Copies the elements in the range, defined by [first, last) to another range beginning at *dest*. The order of the elements that are not removed is preserved.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *FwdIter1*.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

<b>bool pred(const Type1 &amp;a, const Type1 &amp;b);</b>
---

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be

dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *copy\_if* algorithm returns a *hpx::future<ranges::copy\_if\_result<iterator\_t<Rng>, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::copy\_if\_result<iterator\_t<Rng>, FwdIter2>* otherwise. The *copy\_if* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_if_result<typename hpx::traits::range_traits<Rng>::iterator_t<Rng>, FwdIter>> copy_if(
```

Copies the elements in the range, defined by *rng* to another range beginning at *dest*. The order of the elements that are not removed is preserved.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

<code>bool pred(const Type1 &amp;a, const Type1 &amp;b);</code>
---

The signature does not need to have *const &*, but the function must not modify the ob-

jects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *copy\_if* algorithm returns a *hpx::future<ranges::copy\_if\_result<iterator\_t<Rng>, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::copy\_if\_result<iterator\_t<Rng>, FwdIter2>* otherwise. The *copy\_if* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename Sent1, typename FwdIter, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
ranges::copy_if_result<FwdIter1, FwdIter> copy_if(FwdIter1 iter, Sent1 sent, FwdIter dest, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range, defined by [first, last) to another range beginning at *dest*. The order of the elements that are not removed is preserved.

#### Template Parameters

- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *FwdIter1*.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *copy\_if* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename FwdIter, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
```

---

```
ranges::copy_if_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter> copy_if(Rng
&&rng,
FwdIter
dest,
Pred
&&pred,
Proj
&&proj
=
Proj())
```

Copies the elements in the range, defined by *rng* to another range beginning at *dest*. The order of the elements that are not removed is preserved.

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *copy\_if* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/count.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::parallel::util::projection_identity,
typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>,
Proj>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

**Note:** The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *count* algorithm returns a *hpx::future<difference\_type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *std::iterator\_traits<FwdIter>::difference\_type*). The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Proj =
  hpx::parallel::util::projection_identity, typename T = typename hpx::parallel::traits::projected<Iter,
Proj>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<Iter>::difference_type>::type count(Ex

  Pr
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

---

**Note:** The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The *count* algorithm returns a *hpx::future<difference\_type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *std::iterator\_traits<FwdIter>::difference\_type*).

The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename Rng, typename Proj = hpx::parallel::util::projection_identity, typename T =
typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type>
std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::difference_type count(Rng
&&rng,
T
const
&value,
Proj
&&proj
=
Proj())
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename Iter, typename Sent, typename Proj = hpx::parallel::util::projection_identity,
typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>
std::iterator_traits<Iter>::difference_type count(Iter first, Sent last, T const &value, Proj &&proj =
Proj())
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj =
```

```
hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have *const&*, but the function must not modify the ob-

jects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *count\_if* algorithm returns *hpx::future<difference\_type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *std::iterator\_traits<FwdIter>::difference\_type*). The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =  
        hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<Iter>::difference_type>::type count_if
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```
template<typename Rng, typename F, typename Proj = hpx::parallel::util::projection_identity>
std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::difference_type count_if(Rng
    &&rng,
    F
    &&f,
    Proj
    &&proj
    =
    Proj())
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires *F* to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename Iter, typename Sent, typename F, typename Proj =  
    hpx::parallel::util::projection_identity>  
std::iterator_traits<Iter>::difference_type count_if(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

**bool pred(const Type &a);**

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *count* algorithm returns the number of elements satisfying the given criteria.

## hpx/parallel/container\_algorithms/destroy.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename ExPolicy, typename Rng>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type destroy(ExPolicy &policy, Rng &rng, ForwardIt first, ForwardIt last)
```

Destroys objects of type `typename iterator_traits<ForwardIt>::value_type` in the range `[first, last]`.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `last - first` operations.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The `destroy` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```
template<typename ExPolicy, typename Iter, typename Sent>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type destroy(ExPolicy &&policy, Iter first, Sent last)
```

Destroys objects of type `typename iterator_traits<ForwardIt>::value_type` in the range `[first, last]`.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `last - first` operations.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the range (deduced).

- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *destroy* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

template<typename **Rng**>

*hpx::traits::range\_iterator<Rng>::type* **destroy**(*Rng* &&*rng*)

Destroys objects of type typename iterator\_traits<ForwardIt>::value\_type in the range [first, last).

---

**Note:** Complexity: Performs exactly *last - first* operations.

---

**Template Parameters Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The *destroy* algorithm returns *void*.

template<typename **Iter**, typename **Sent**>

inline *Iter* **destroy**(*Iter* first, *Sent* last)

Move objects to uninitialized memory.

Destroys objects of type typename iterator\_traits<ForwardIt>::value\_type in the range [first, last).

---

**Note:** Complexity: Performs exactly *last - first* operations.

---

**Template Parameters**

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Iter** – : iterator to the elements
- **Value** – : typename of the object to construct

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **ptr** – [in] : pointer to the memory where to construct the object
- **R** – [in] : range to move

**Returns** The *destroy* algorithm returns *void*.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>

*hpx::parallel::util::detail::algorithm\_result<ExPolicy, FwdIter>::type* **destroy\_n**(*ExPolicy* &&*policy*,  
*FwdIter* *first*, *Size*  
*count*)

Destroys objects of type typename iterator\_traits<ForwardIt>::value\_type in the range [first, first + count).

The operations in the parallel *destroy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel `destroy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `count` operations, if `count > 0`, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

**Returns** The `destroy_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `destroy_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename FwdIter, typename Size>
FwdIter destroy_n(FwdIter first, Size count)
```

Destroys objects of type `typename iterator_traits<ForwardIt>::value_type` in the range `[first, first + count)`.

---

**Note:** Complexity: Performs exactly `count` operations, if `count > 0`, no assignments otherwise.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

**Returns** The `destroy_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

## hpx/parallel/container\_algorithms/ends\_with.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **ranges**

### Functions

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred =  
ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 =  
parallel::util::projection_identity>  
bool ends_with(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1  
= Proj1(), Proj2 &&proj2 = Proj2())
```

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel *ends\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

#### Template Parameters

- **Iter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the end source iterators used(deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a input iterator.
- **Sent2** – The type of the end destination iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

#### Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate *is* invoked.

**Returns** The *ends\_with* algorithm returns *bool*. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename
Sent2, typename Pred = ranges::equal_to, typename Proj1 = parallel::util::projection_identity,
typename Proj2 = parallel::util::projection_identity>
parallel::util::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &&policy, FwdIter1
first1, Sent1 last1, FwdIter2
first2, Sent2 last2, Pred
&&pred = Pred(), Proj1
&&proj1 = Proj1(), Proj2
&&proj2 = Proj2())
```

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel *ends\_with* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *ends\_with* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used(deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **FwdIter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the end destination iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate *is* invoked.

**Returns** The *ends\_with* algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```
template<typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
bool ends_with(Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(),
                Proj2 &&proj2 = Proj2())
```

Checks whether the second range *rng2* matches the suffix of the first range *rng1*.

The assignments in the parallel *ends\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most  $\min(N_1, N_2)$  applications of the predicate and both projections.

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function for the destination range. This defaults to `util::projection_identity`

#### Parameters

- **rng1** – Refers to the source range.
- **rng2** – Refers to the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate *is* invoked.

**Returns** The *ends\_with* algorithm returns `bool`. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to,
        typename Proj1 = parallel::util::projection_identity, typename Proj2 =
        parallel::util::projection_identity>
```

---

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &&policy, Rng1
&&rng1, Rng2 &&rng2,
Pred &&pred = Pred(),
Proj1 &&proj1 = Proj1(),
Proj2 &&proj2 =
Proj2())
```

Checks whether the second range *rng2* matches the suffix of the first range *rng1*.

The assignments in the parallel *ends\_with* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *ends\_with* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the source range.
- **rng2** – Refers to the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate *is* invoked.

**Returns** The *ends\_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

## hpx/parallel/container\_algorithms/equal.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
         typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =
         hpx::parallel::util::projection_identityhpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, Iter1
    first1, Sent1 last1, Iter2 first2,
    Sent2 last2, Pred &&op =
    Pred(), Proj1 &&proj1 =
    Proj1(), Proj2 &&proj2 =
    Proj2())
```

Returns true if the range [*first1*, *last1*] is equal to the range [*first2*, *last2*], and false otherwise.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate *f*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [*first1*,*last1*),  $*i$  equals  $(\text{first2} + (i - \text{first1}))$ . This overload of *equal* uses operator== to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to*<>
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to *util::projection\_identity*

- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1]` does not equal the length of the range `[first2, last2]`, it returns false.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
ExPolicy, bool>::type equal(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&cop = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range `[first1, last1]` is equal to the range starting at `first2`, and false otherwise.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $last1 - first1$  applications of the predicate  $f$ .

---

---

**Note:** The two ranges are considered equal if, for every iterator  $i$  in the range `[first1, last1]`,  $*i$  equals

$*(\text{first2} + (\text{i} - \text{first1}))$ . This overload of equal uses operator $\text{==}$  to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *equal* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `bool` otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
bool equal(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate *f*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1),  $^*\text{i}$  equals  $*(\text{first2} + (\text{i} - \text{first1}))$ . This overload of equal uses operator $\text{==}$  to determine if two elements are equal.

---

**Template Parameters**

- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to util::projection\_identity
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to util::projection\_identity

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 =
    hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
bool equal(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2
    &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *f*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses operator== to determine if two elements are equal.

---

### Template Parameters

- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

## hpx/parallel/container\_algorithms/exclusive\_scan.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent, typename OutIter, typename T = typename  
std::iterator_traits<InIter>::value_type, typename Op = std::plus<T>>  
exclusive_scan_result<InIter, OutIter> exclusive_scan(InIter first, Sent last, OutIter dest, T init, Op  
&&op = Op())
```

Assigns through each iterator *i* in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,    *a*1,    ... ,    *a*K),    GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*M, ..., *a*N)) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for **FwdIter1**.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The *exclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename T = typename std::iterator_traits<FwdIter1>::value_type, typename Op = std::plus<T>>
```

*parallel::util::detail::algorithm\_result<ExPolicy, exclusive\_scan\_result<FwdIter1, FwdIter2>>::type* **exclusive\_scan**(*ExPolicy*, *FwdIter1*, *FwdIter2*, *T*, *Op*, *policy*, *first*, *last*)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*K), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*M, ..., *a*N)) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter1*.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `exclusive_scan` algorithm returns a `hpx::future<util::in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `util::in_out_result<FwdIter1, FwdIter2>` otherwise. The `exclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename O, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type, typename Op = std::plus<T>>
exclusive_scan_result<traits::range_iterator_t<Rng>, O> exclusive_scan(Rng &&rng, O dest, T init,
Op &&op = Op())
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, init, \*first, ..., \*(first + (i - result) - 1))

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the  $i$ th input element in the  $i$ th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate `std::plus<T>`.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate

should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `exclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename O, typename T = typename  
std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type, typename Op = std::plus<T>>  
parallel::util::detail::algorithm_result<ExPolicy, exclusive_scan_result<traits::range_iterator_t<Rng>, O>>::type exclusive
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM( $+, init, *first, \dots, *(first + (i - result) - 1)$ )

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the  $i$ th input element in the  $i$ th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate `std::plus<T>`.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM( $+, a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM( $+, a_1, \dots, a_K$ )
    - GENERALIZED\_NONCOMMUTATIVE\_SUM( $+, a_M, \dots, a_N$ ) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `exclusive_scan` algorithm returns a `hpx::future<util::in_out_result<traits::range_iterator_t<Rng>, O>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `util::in_out_result<traits::range_iterator_t<Rng>, O>` otherwise. The `exclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/fill.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Rng, typename T = typename
std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type fill(
```

Assigns the given value to the elements in the range [first, last).

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *void*).

```
template<typename ExPolicy, typename Iter, typename Sent, typename T = typename std::iterator_traits<Iter>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type fill(ExPolicy &&policy, Iter first,
Sent last, T const &value)
```

Assigns the given value to the elements in the range [first, last).

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *void*).

```
template<typename Rng, typename T = typename
std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
hpx::traits::range_iterator_t<Rng> fill(Rng &&rng, T const &value)
```

Assigns the given value to the elements in the range [first, last).

**Note:** Complexity: Performs exactly *last - first* assignments.

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *fill* algorithm returns *void*.

## hpx/parallel/container\_algorithms/find.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter, typename Sent, typename Proj =
hpx::parallel::util::projection_identity, typename T = typename hpx::parallel::traits::projected<Iter,
Proj>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type find(ExPolicy &&policy, Iter first,
Sent last, T const &val, Proj
&&proj = Proj())
```

Returns the first element in the range [first, last) that is equal to value

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the operator==().

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::parallel::util::projection_identity,
typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>,
Proj>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type find(ExPolicy  
    &&policy,  
    Rng  
    &&rng,  
    T  
    const  
&val,  
    Proj  
&&proj  
    =  
    Proj())
```

Returns the first element in the range [first, last) that is equal to value

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the operator==().

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **val** – the value to compare the elements to
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename Iter, typename Sent,
typename Proj = hpx::parallel::util::projection_identity,
typename T = typename hpx::parallel::traits::projected<Iter,
Proj>::value_type> hpx::parallel::util::detail::algorithm_result< ExPolicy,
Iter >::type Iter find (Iter first, Sent last, T const &val, Proj &&proj=Proj())
```

Returns the first element in the range [first, last) that is equal to value

---

**Note:** Complexity: At most last - first applications of the operator==().

---

#### Template Parameters

- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter*.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename Rng, typename Proj = hpx::parallel::util::projection_identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type> hpx::traits::range_iterator<Rng>::type find(Rng &&rng, T const &val, Proj &&proj = Proj())
```

Returns the first element in the range [first, last) that is equal to value

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the operator==().

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **val** – the value to compare the elements to
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename Proj = hpx::parallel::util::projection_identity> hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type find_if(ExPolicy &&policy, Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range [first, last) for which predicate *pred* returns true

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *find\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if* algorithm returns the first element in the range [first, last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj =  
        hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type find_if(ExPolicy  
&  
Rng  
&  
Pred  
&  
Proj  
=
```

Returns the first element in the range *rng* for which predicate *pred* returns true

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *find\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename Iter, typename Sent, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
Iter find_if(Iter first, Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range [first, last) for which predicate *pred* returns true

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter*.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find\_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename Rng, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng>::type find_if(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range *rng* for which predicate *pred* returns true

**Note:** Complexity: At most last - first applications of the predicate.

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find\_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename Proj =
hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type find_if_not(ExPolicy &&policy,
Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range [first, last) for which predicate *f* returns false

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *find\_if\_not* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if\_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
```

---

`hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type find_if_no`

Returns the first element in the range *rng* for which predicate *f* returns false

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find\_if\_not* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if\_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename Iter, typename Sent, typename Pred, typename Proj =  
    hpx::parallel::util::projection_identity>  
Iter find_if_not(Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range [first, last) for which predicate *f* returns false

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

`bool pred(const Type &a);`

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *find\_if\_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename Rng, typename Pred, typename Proj = hpx::parallel::util::projection_identity>  
hpx::traits::range_iterator<Rng>::type find_if_not(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range *rng* for which predicate *f* returns false

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.

- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The `find_if_not` algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type find_end(
```

Returns the last subsequence of elements *rng2* found in the range *rng* using the given predicate *f* to compare elements.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $S^*(N-S+1)$  comparisons where  $S = \text{distance}(\text{begin}(\text{rng2}), \text{end}(\text{rng2}))$  and  $N = \text{distance}(\text{begin}(\text{rng}), \text{end}(\text{rng}))$ .

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal.

The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t<Rng>* and *iterator\_t<Rng2>* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced *iterator\_t<Rng1>* as a projection operation before the function *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced *iterator\_t<Rng2>* as a projection operation before the function *op* is invoked.

**Returns** The *find\_end* algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *iterator\_t<Rng>* otherwise. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence *rng2* in range *rng*. If the length of the subsequence *rng2* is greater than the length of the range *rng*, *end(rng)* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *end(rng)* is also returned.

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =
hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter1>::type find_end(ExPolicy &&policy, Iter1
first1, Sent1 last1, Iter2
first2, Sent2 last2, Pred
&&op = Pred(), Proj1
&&proj1 = Proj1(), Proj2
&&proj2 = Proj2())
```

Returns the last subsequence of elements [first2, last2) found in the range [first1, last1) using the given predicate *f* to compare elements.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find\_end* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $S^*(N-S+1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t<Rng>* and *iterator\_t<Rng2>* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced *iterator\_t<Rng1>* as a projection

operation before the function *op* is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced *iterator\_t<Rng2>* as a projection operation before the function *op* is invoked.

**Returns** The *find\_end* algorithm returns a *hpx::future<iterator\_t<Rng>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *iterator\_t<Rng>* otherwise. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence *rng2* in range *rng*. If the length of the subsequence *rng2* is greater than the length of the range *rng*, *end(rng)* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *end(rng)* is also returned.

```
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 =
hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng1>::type find_end(Rng1 &&rng, Rng2 &&rng2, Pred &&op = Pred(),
Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements *rng2* found in the range *rng* using the given predicate *f* to compare elements.

This overload of *find\_end* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $S^*(N-S+1)$  comparisons where  $S = \text{distance}(\text{begin}(\text{rng2}), \text{end}(\text{rng2}))$  and  $N = \text{distance}(\text{begin}(\text{rng}), \text{end}(\text{rng}))$ .

---

### Template Parameters

- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to *util::projection\_identity*

### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t<Rng>* and *iterator\_t<Rng2>* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced *iterator\_t<Rng1>* as a projection operation before the function *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of

the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

**Returns** The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
Iter1 find_end(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements [first2, last2) found in the range [first1, last1) using the given predicate `f` to compare elements.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

---

**Note:** Complexity: at most  $S^*(N-S+1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

### Template Parameters

- **Iter1** – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the ob-

jects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t*<*Rng*> and *iterator\_t*<*Rng2*> can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced *iterator\_t*<*Rng1*> as a projection operation before the function *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced *iterator\_t*<*Rng2*> as a projection operation before the function *op* is invoked.

**Returns** The *find\_end* algorithm returns an iterator to the beginning of the last subsequence *rng2* in range *rng*. If the length of the subsequence *rng2* is greater than the length of the range *rng*, *end(rng)* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *end(rng)* is also returned.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity> hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type find_firs
```

Searches the range *rng1* for any elements in the range *rng2*. Uses binary predicate *p* to compare elements

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most ( $S*N$ ) comparisons where  $S = \text{distance}(\text{begin}(\text{rng2}), \text{end}(\text{rng2}))$  and  $N = \text{distance}(\text{begin}(\text{rng1}), \text{end}(\text{rng1}))$ .

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in *rng1*.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in *rng2*.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t<Rng1>* and *iterator\_t<Rng2>* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *iterator\_t<Rng1>* before the function *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *iterator\_t<Rng2>* before the function *op* is invoked.

**Returns** The *find\_end* algorithm returns a `hpx::future<iterator_t<Rng1>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *iterator\_t<Rng1>* otherwise. The *find\_first\_of* algorithm returns an iterator to the first element in the range *rng1* that is equal to an element from the range *rng2*. If the length of the subsequence *rng2* is greater than the length of the range *rng1*, *end(rng1)* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *end(rng1)* is also returned.

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,  
typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =  
hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter1>::type find_first_of(ExPolicy &&policy,  
Iter1 first1, Sent1  
last1, Iter2 first2,  
Sent2 last2, Pred  
&&op = Pred(),  
Proj1 &&proj1 =  
Proj1(), Proj2  
&&proj2 = Proj2())
```

Searches the range [first1, last1) for any elements in the range [first2, last2). Uses binary predicate *p* to compare elements

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $(S^*N)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in *rng1*.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in *rng2*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t<Rng1>* and *iterator\_t<Rng2>* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *iterator\_t<Rng1>* before the function *op* is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng2>` before the function `op` is invoked.

**Returns** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng1>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng1>` otherwise. The `find_first_of` algorithm returns an iterator to the first element in the range `rng1` that is equal to an element from the range `rng2`. If the length of the subsequence `rng2` is greater than the length of the range `rng1`, `end(rng1)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng1)` is also returned.

```
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 =
hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng1>::type find_first_of(Rng1 &&rng1, Rng2 &&rng2, Pred &&op =
Pred(), Proj1 &&proj1 = Proj1(), Proj2
&&proj2 = Proj2())
```

Searches the range `rng1` for any elements in the range `rng2`. Uses binary predicate `p` to compare elements

This overload of `find_first_of` is available if the user decides to provide the algorithm their own predicate `op`.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S = \text{distance}(\text{begin}(rng2), \text{end}(rng2))$  and  $N = \text{distance}(\text{begin}(rng1), \text{end}(rng1))$ .

---

### Template Parameters

- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in `rng1`.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in `rng2`.

### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng1>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng1>` before the function `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng2>` before the function `op` is invoked.

**Returns** The *find\_first\_of* algorithm returns an iterator to the first element in the range *rng1* that is equal to an element from the range *rng2*. If the length of the subsequence *rng2* is greater than the length of the range *rng1*, *end(rng1)* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *end(rng1)* is also returned.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred =  
equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =  
hpx::parallel::util::projection_identity>  
Iter1 find_first_of(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1  
&&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first1, last1) for any elements in the range [first2, last2). Uses binary predicate *p* to compare elements

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most (*S*\**N*) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

---

#### Template Parameters

- **Iter1** – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in *rng1*.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in *rng2*.

#### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *iterator\_t<Rng1>* and *iterator\_t<Rng2>* can be dereferenced and then implicitly converted

to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *iterator\_t<Rng1>* before the function *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *iterator\_t<Rng2>* before the function *op* is invoked.

**Returns** The *find\_first\_of* algorithm returns an iterator to the first element in the range *rng1* that is equal to an element from the range *rng2*. If the length of the subsequence *rng2* is greater than the length of the range *rng1*, *end(rng1)* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *end(rng1)* is also returned.

## hpx/parallel/container\_algorithms/for\_each.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent, typename F, typename Proj =
    hpx::parallel::util::projection_identity>
for_each_result<InIter, F> for_each(InIter first, Sent last, F &&f, Proj &&proj = Proj())
    Applies f to the result of dereferencing every iterator in the range [first, last).
```

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

---

**Note:** Complexity: Applies *f* exactly *last - first* times.

---

#### Template Parameters

- **InIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** {last, HPX\_MOVE(f)} where last is the iterator corresponding to the input sentinel last.

```
template<typename Rng, typename F, typename Proj = hpx::parallel::util::projection_identity>
for_each_result<typename hpx::traits::range_iterator<Rng>::type, F> for_each(Rng &&rng, F &&f,
                                         Proj &&proj = Proj())
```

Applies *f* to the result of dereferencing every iterator in the given range *rng*.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

---

**Note:** Complexity: Applies *f* exactly *size(rng)* times.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** {std::end(rng), HPX\_MOVE(f)}

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F, typename Proj =
hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type for_each(ExPolicy &&policy,
                                         FwdIter first, Sent last,
                                         F &&f, Proj &&proj =
                                         Proj())
```

Applies *f* to the result of dereferencing every iterator in the range [first, last).

If  $f$  returns a result, the result is ignored.

If the type of  $first$  satisfies the requirements of a mutable iterator,  $f$  may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of  $for\_each$  does not return a copy of its  $Function$  parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies  $f$  exactly  $last - first$  times.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of  $for\_each$  requires  $F$  to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The  $for\_each$  algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj =
hpx::parallel::util::projection_identity>
```

*hpx::parallel::util::detail::algorithm\_result<ExPolicy, typename hpx::traits::range\_iterator<Rng>::type>::type* **for\_each**(*E*, *f*, *first*, *last*)

Applies *f* to the result of dereferencing every iterator in the given range *rng*.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies *f* exactly *size(rng)* times.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have **const&**. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *for\_each* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

```
template<typename InIter, typename Size, typename F, typename Proj =
hpx::parallel::util::projection_identity>
for_each_n_result<InIter, F> for_each_n(InIter first, Size count, F &&f, Proj &&proj = Proj())
```

Applies *f* to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

---

**Note:** Complexity: Applies *f* exactly *count* times.

---

#### Template Parameters

- **InIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have *const&*. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** It returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F, typename Proj =
hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type for_each_n(ExPolicy &&policy,
FwdIter first, Size count, F &&f, Proj &&proj = Proj())
```

Applies  $f$  to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

If  $f$  returns a result, the result is ignored.

If the type of  $first$  satisfies the requirements of a mutable iterator,  $f$  may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies  $f$  exactly  $count$  times.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply  $f$  to.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires  $F$  to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have *const&*. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *for\_each* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

# Functions

```
template<typename ExPolicy, typename Iter, typename Sent, typename ...Args>
hpx::parallel::util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, Iter
first, Sent last, Args&&...
args)
```

The `for_loop` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: *Iter* shall meet the requirements of a forward iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of MoveConstructible.

**Effects:** Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the  $\text{args}$  parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the iteration variable (forward iterator).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The `for_loop` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```
template<typename Iter, typename Sent, typename ...Args>
void for_loop(Iter first, Sent last, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires:** `Iter` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

**Effects:** Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then

the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

### Template Parameters

- **Iter** – The type of the iteration variable (input iterator).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename R, typename ...Args>
hpx::parallel::util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, R
&&rng, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by a range. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: `Rng::iterator` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of `MoveConstructible`.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **R** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The *for\_loop* algorithm returns a *hpx::future<void>* if the execution policy is of type *hpx::execution::sequenced\_task\_policy* or *hpx::execution::parallel\_task\_policy* and returns *void* otherwise.

```
template<typename Rng, typename ...Args>
void for_loop(Rng &&rng, Args&&... args)
```

The *for\_loop* implements loop functionality over a range specified by a range. These algorithms resemble *for\_each* from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for\_loop without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: `Rng::iterator` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of `MoveConstructible`.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **rng** – Refers to the of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

template<typename **ExPolicy**, typename **Iter**, typename **Sent**, typename **S**, typename ...**Args**>

```
parallel::util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy &&policy,  
Iter first, Sent last, S  
stride, Args&&...  
args)
```

The `for_loop_strided` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: `Iter` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

Effects: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

Complexity: Applies `f` exactly once for each element of the input sequence.

Remarks: If `f` returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the iteration variable (forward iterator).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `Iter`.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have **const&**. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The *for\_loop\_strided* algorithm returns a *hpx::future<void>* if the execution policy is of type *hpx::execution::sequenced\_task\_policy* or *hpx::execution::parallel\_task\_policy* and returns *void* otherwise.

```
template<typename Iter, typename Sent, typename S, typename ...Args>
void for_loop_strided(Iter first, Sent last, S stride, Args&&... args)
```

The *for\_loop\_strided* implements loop functionality over a range specified by iterator bounds. These algorithms resemble *for\_each* from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of *for\_loop\_strided* without specifying an execution policy is equivalent to specifying *hpx::execution::seq* as the execution policy.

**Requires:** *Iter* shall meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

**Effects:** Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

**Complexity:** Applies *f* exactly once for each element of the input sequence.

**Remarks:** If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using *advance* and *distance*.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

### Template Parameters

- **Iter** – The type of the iteration variable (input iterator).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename Rng, typename S, typename ...Args>
hpx::parallel::util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy
    &&policy, Rng
    &&rng, S stride,
    Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by a range. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: `Rng::iterator` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of `MoveConstructible`.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding  $f$ , an additional argument is passed to each application of  $f$  as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Rng::iterator meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The `for_loop_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```
template<typename Rng, typename S, typename ...Args>
void for_loop_strided(Rng &&rng, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by a range. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop_strided` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: *Rng::iterator* shall meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using *advance* and *distance*.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if *Rng::iterator* meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last] should expose a signature equivalent to:

```
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have *const&*. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

## hpx/parallel/container\_algorithms/generate.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Rng, typename F>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type generate(ExPolicy &policy, Rng &rng, F &f, std::size_t distance, std::random_access_iterator_tag)
```

Assign each element in range [first, last) a value generated by the given function object f

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

Ret <b>fun()</b> ;
--------------------

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type generate(ExPolicy &&policy, Iter
first, Sent last, F &&f)
```

Assign each element in range [first, last) a value generated by the given function object f

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *distance(first, last)* invocations of f and assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires F to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

```
template<typename Rng, typename F>
hpx::traits::range_iterator<Rng>::type generate(Rng &&rng, F &&f)
```

Assign each element in range [first, last) a value generated by the given function object f

---

**Note:** Complexity: Exactly *distance(first, last)* invocations of f and assignments.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires F to meet the requirements of *CopyConstructible*.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns *last*.

```
template<typename Iter, typename Sent, typename F>
Iter generate(Iter first, Sent last, F &&f)
```

Assign each element in range [first, last) a value generated by the given function object f

**Note:** Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

#### Template Parameters

- **Iter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type generate_n(ExPolicy &&policy,
                                                                           FwdIter first, Size
                                                                           count, F &&f)
```

Assigns each element in range [first, first+count) a value generated by the given function object g.

The assignments in the parallel *generate\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly *count* invocations of *f* and assignments, for *count* > 0.

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply  $f$  to.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires  $F$  to meet the requirements of *CopyConstructible*.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *last*.

```
template<typename FwdIter, typename Size, typename F>
FwdIter generate_n(FwdIter first, Size count, F &&f)
```

Assigns each element in range [first, first+count) a value generated by the given function object *g*.

---

**Note:** Complexity: Exactly *count* invocations of *f* and assignments, for *count* > 0.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply  $f$  to.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires  $F$  to meet the requirements of *CopyConstructible*.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

**Returns** The *replace\_if* algorithm returns *last*.

## **hpx/parallel/container\_algorithms/includes.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## namespace **hpx**

## namespace **ranges**

# Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
typename Pred = hpx::parallel::v1::detail::less, typename Proj1 =
hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type includes(ExPolicy &&policy, Iter1
    first1, Sent1 last1, Iter2
    first2, Sent2 last2, Pred
    &&op = Pred(), Proj1
    &&proj1 = Proj1(), Proj2
    &&proj2 = Proj2())
```

Returns true if every element from the sorted range [`first2`, `last2`] is found within the sorted range [`first1`, `last1`]. Also returns true if [`first2`, `last2`] is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** At most  $2*(N1+N2-1)$  comparisons, where  $N1 = \text{std::distance(first1, last1)}$  and  $N2 = \text{std::distance(first2, last2)}$ .

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  - **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
  - **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
  - **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
  - **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
  - **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
  - **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`

- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2]` is found within the sorted range `[first1, last1]`. Also returns true if `[first2, last2]` is empty.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = hpx::parallel::v1::detail::less, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
bool includes(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if every element from the sorted range `[first2, last2]` is found within the sorted range `[first1, last1]`. Also returns true if `[first2, last2]` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

---

**Note:** At most  $2*(N1+N2-1)$  comparisons, where  $N1 = \text{std::distance(first1, last1)}$  and  $N2 = \text{std::distance(first2, last2)}$ .

---

**Template Parameters**

- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for `Iter2`.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to *util::projection\_identity*

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *includes* algorithm returns true every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred =
    hpx::parallel::v1::detail::less, typename Proj1 = hpx::parallel::util::projection_identity, typename
    Proj2 = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type includes(ExPolicy &&policy, Rng1
    &&rng1, Rng2 &&rng2,
    Pred &&op = Pred(),
    Proj1 &&proj1 = Proj1(),
    Proj2 &&proj2 = Proj2())
```

Returns true if every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** At most  $2*(N1+N2-1)$  comparisons, where  $N1 = \text{std::distance(first1, last1)}$  and  $N2 = \text{std::distance(first2, last2)}$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *includes* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `bool` otherwise. The *includes* algorithm returns true every element from the sorted range  $[first2, last2]$  is found within the sorted range  $[first1, last1]$ . Also returns true if  $[first2, last2]$  is empty.

```
template<typename Rng1, typename Rng2, typename Pred = hpx::parallel::v1::detail::less, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
bool includes(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if every element from the sorted range  $[first2, last2]$  is found within the sorted range  $[first1, last1]$ . Also returns true if  $[first2, last2]$  is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*.

---

**Note:** At most  $2*(N1+N2-1)$  comparisons, where  $N1 = \text{std::distance(first1, last1)}$  and  $N2 =$

---

std::distance(first2, last2).

### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to *util::projection\_identity*

### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *includes* algorithm returns true every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty.

## hpx/parallel/container\_algorithms/inclusive\_scan.hpp

namespace **hpx**

    namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Rng, typename Comp = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_heap(ExPolicy &&policy, Rng &&rng, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to *bool*, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* is invoked.

**Returns** The *is\_heap* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *is\_heap*

algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Comp =
  hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_heap(ExPolicy &&policy, Iter
  first, Sent last, Comp
  &&comp = Comp(), Proj
  &&proj = Proj())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to *bool*, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* is invoked.

**Returns** The *is\_heap* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *is\_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename Rng, typename Comp = hpx::parallel::v1::detail::less, typename Proj =
  hpx::parallel::util::projection_identity>
bool is_heap(Rng &&rng, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The

function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_heap* algorithm returns *bool*. The *is\_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename Iter, typename Sent, typename Comp = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
bool is_heap(Iter first, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

#### Template Parameters

- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter1*.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_heap* algorithm returns *bool*. The *is\_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename ExPolicy, typename Rng, typename Comp = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type is_heap_until
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to *bool*, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* is invoked.

**Returns** The *is\_heap\_until* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter* otherwise. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning

at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Comp =  
hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type is_heap_until(ExPolicy &&policy,  
Iter first, Sent sent,  
Comp &&comp =  
Comp(), Proj  
&&proj = Proj())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* is invoked.

**Returns** The *is\_heap\_until* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter* otherwise. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

---

```
template<typename Rng, typename Comp = hpx::parallel::v1::detail::less, typename Proj =
hpx::parallel::util::projection_identityhpx::traits::range_iterator<Rng>::type is_heap_until(Rng &&rng, Comp &&comp = Comp(), Proj
&&proj = Proj())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*] is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_heap\_until* algorithm returns *RandIter*. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*] is a max heap.

---

```
template<typename Iter, typename Sent, typename Comp = hpx::parallel::v1::detail::less, typename
Proj = hpx::parallel::util::projection_identityIter is_heap_until(Iter first, Sent sent, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*] is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

---

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 \* N applications of the projection *proj*, where N = last - first.

---

#### Template Parameters

- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter1*.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* is invoked.

**Returns** The *is\_heap\_until* algorithm returns *RandIter*. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [*first*, *it*) is a max heap.

## hpx/parallel/container\_algorithms/is\_partitioned.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent, typename Pred, typename Proj =  
    hpx::parallel::util::projection_identity>
```

```
bool is_partitioned(FwdIter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Determines if the range [*first*, *last*) is partitioned.

---

**Note:** Complexity: at most (*N*) predicate evaluations where *N* = distance(*first*, *last*).

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::parallel::util::projection\_identity*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_partitioned* algorithm returns *bool*. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range [first, last) contains less than two elements, the function is always true.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred, typename Proj =  
    hpx::parallel::util::projection_identity>  
parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_partitioned(ExPolicy &&policy,  
    FwdIter first, Sent last,  
    Pred &&pred, Proj  
    &&proj = Proj())
```

Determines if the range [first, last) is partitioned.

The predicate operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (N) predicate evaluations where N = distance(first, last).

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of the function/function object to use (deduced). *Pred* must be *CopyConstructible* when using a parallel policy.
- **Proj** – The type of an optional projection function. This defaults to *hpx::parallel::util::projection\_identity*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

<b>bool pred(<i>const Type &amp;a</i>);</b>
---

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_partitioned* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task\_execution\_policy* and returns *bool* otherwise. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range [first, last) contains less than two elements, the function is always true.

```
template<typename Rng, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
bool is_partitioned(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Determines if the range *rng* is partitioned.

---

**Note:** Complexity: at most (N) predicate evaluations where  $N = \text{std::size}(\text{rng})$ .

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::parallel::util::projection\_identity*.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_partitioned* algorithm returns *bool*. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range *rng* contains less than two elements, the function is always true.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj =
hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_partitioned(ExPolicy &&policy, Rng
&&rng, Pred &&pred,
Proj &&proj = Proj())
```

Determines if the range [first, last) is partitioned.

The predicate operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (N) predicate evaluations where  $N = \text{std::size}(\text{rng})$ .

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). *Pred* must be *CopyConstructible* when using a parallel policy.
- **Proj** – The type of an optional projection function. This defaults to *hpx::parallel::util::projection\_identity*.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* is invoked.

**Returns** The *is\_partitioned* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task\_execution\_policy* and returns *bool* otherwise. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range *rng* contains less than two elements, the function is always true.

**hpx/parallel/container\_algorithms/is\_sorted.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

**Functions**

```
template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identitybool is_sorted(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range [first, last) is sorted. Uses *pred* to compare elements.

The comparison operations in the parallel *is\_sorted* algorithm executes in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .  $S = \text{number of partitions}$

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_sorted* algorithm returns a *bool*. The *is\_sorted* algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred =  
hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_sorted(ExPolicy &&policy,  
FwdIter first, Sent last,  
Pred &&pred = Pred(),  
Proj &&proj = Proj())
```

Determines if the range [first, last) is sorted. Uses *pred* to compare elements.

The comparison operations in the parallel *is\_sorted* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_sorted* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{distance(first, last)}$ .  $S = \text{number of partitions}$

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is\_sorted* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_sorted* algorithm returns a `hpx::future<bool>` if the execution policy is of type *task\_execution\_policy* and returns `bool` otherwise. The *is\_sorted* algorithm returns a `bool` if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```
template<typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
bool is_sorted(Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range *rng* is sorted. Uses *pred* to compare elements.

The comparison operations in the parallel *is\_sorted* algorithm executes in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{size}(\text{rng})$ .  $S = \text{number of partitions}$

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `is_sorted` algorithm returns a `bool`. The `is_sorted` algorithm returns true if each element in the rng satisfies the predicate passed. If the range `rng` contains less than two elements, the function always returns true.

```
template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_sorted(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range `rng` is sorted. Uses `pred` to compare elements.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{size}(\text{rng})$ .  $S = \text{number of partitions}$

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_sorted* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task\_execution\_policy* and returns *bool* otherwise. The *is\_sorted* algorithm returns a *bool* if each element in the range *rng* satisfies the predicate passed. If the range *rng* contains less than two elements, the function always returns true.

```
template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
FwdIter is_sorted_until(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel *is\_sorted\_until* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most ( $N+S-1$ ) comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .  $S = \text{number of partitions}$

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_sorted\_until* algorithm returns a *FwdIter*. The *is\_sorted\_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type is_sorted_until(ExPolicy
    &&policy,
    FwdIter first,
    Sent last,
    Pred &&pred
    = Pred(), Proj
    &&proj =
    Proj())
```

Returns the first element in the range [*first*, *last*] that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel *is\_sorted\_until* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_sorted\_until* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most ( $N+S-1$ ) comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .  $S = \text{number of partitions}$

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is\_sorted\_until* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_sorted\_until* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *is\_sorted\_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng>::type is_sorted_until(Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range *rng* that is not sorted. Uses a predicate to compare elements or the less than operator.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{size}(\text{rng})$ .  $S = \text{number of partitions}$

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is\_sorted\_until* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::less<>*
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *is\_sorted\_until* returns *FwdIter*. The *is\_sorted\_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type is_sorted_
```

Returns the first element in the range `rng` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N = \text{size}(\text{rng})$ .  $S = \text{number of partitions}$

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` is invoked.

**Returns** The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

## hpx/parallel/container\_algorithms/lexicographical\_compare.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter1, typename Sent1, typename InIter2, typename Sent2, typename Proj1
= hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity,
typename Pred = hpx::parallel::v1::detail::less>
bool lexicographical_compare(InIter1 first1, Sent1 last1, InIter2 first2, Sent2 last2, Pred &&pred =
    Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std}::\text{distance}(\text{first1}, \text{last1})$  and  $N2 = \text{std}::\text{distance}(\text{first2}, \text{last2})$ .

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
  - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
  - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
  - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
  - An empty range is lexicographically *less* than any non-empty range
  - Two empty ranges are lexicographically *equal*
- 

### Template Parameters

- **InIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter1.
- **InIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function for FwdIter1. This defaults to `util::projection_identity`

- **Proj2** – The type of an optional projection function for FwdIter2. This defaults to `util::projection_identity`

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The `lexicographically_compare` algorithm returns `bool`. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity, typename Pred = hpx::parallel::v1::detail::less>
parallel::util::algorithm_result<ExPolicy, bool>::type lexicographical_compare(ExPolicy &&policy, FwdIter1 first1, Sent1 last1, FwdIter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 =$

---

`std::distance(first1, last)` and `N2 = std::distance(first2, last2)`.

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
  - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
  - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
  - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
  - An empty range is lexicographically *less* than any non-empty range
  - Two empty ranges are lexicographically *equal*
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter1.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function for FwdIter1. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function for FwdIter2. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *lexicographically\_compare* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `bool` otherwise. The *lexicographically\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2], it returns false.

```
template<typename Rng1, typename Rng2, typename Proj1 = hpx::parallel::util::projection_identity,
typename Proj2 = hpx::parallel::util::projection_identity, typename Pred =
hpx::parallel::v1::detail::less>
bool lexicographical_compare(Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(), Proj1
&&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range rng1 is lexicographically less than the second range rng2. uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std::distance}(\text{std::begin(rng1)}, \text{std::end(rng1)})$  and  $N2 = \text{std::distance}(\text{std::begin(rng2)}, \text{std::end(rng2)})$ .

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
  - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
  - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
  - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
  - An empty range is lexicographically *less* than any non-empty range
  - Two empty ranges are lexicographically *equal*
- 

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function for elements of the first range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function for elements of the second range. This defaults to *util::projection\_identity*

#### Parameters

- **rng1** – Refers to the sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *lexicographically\_compare* algorithm returns *bool*. The *lexicographically\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Proj1 =
  hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity,
  typename Pred = hpx::parallel::v1::detail::less>
parallel::util::detail::algorithm_result<ExPolicy, bool>::type lexicographical_compare(ExPolicy
  &&policy,
  Rng1
  &&rng1,
  Rng2
  &&rng2,
  Pred
  &&pred =
  Pred(),
  Proj1
  &&proj1 =
  Proj1(),
  Proj2
  &&proj2 =
  Proj2())
```

Checks if the first range *rng1* is lexicographically less than the second range *rng2*. uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std}::distance(\text{std}::begin(rng1), \text{std}::end(rng1))$  and  $N2 = \text{std}::distance(\text{std}::begin(rng2), \text{std}::end(rng2))$ .

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
  - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
  - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
  - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
  - An empty range is lexicographically *less* than any non-empty range
  - Two empty ranges are lexicographically *equal*
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function for elements of the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function for elements of the second range. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *lexicographically\_compare* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *lexicographically\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

## [hpx/parallel/container\\_algorithms/make\\_heap.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter, typename Sent, typename Comp, typename Proj =  
        hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type make_heap(ExPolicy &&policy, Iter  
first, Sent last, Comp  
&&comp, Proj &&proj =  
Proj{})
```

Constructs a *max heap* in the range [first, last).

The predicate operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *sequential\_execution\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *parallel\_execution\_policy* or *parallel\_task\_execution\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (3\*N) comparisons where *N* = distance(first, last).

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```
bool comp(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```
template<typename ExPolicy, typename Rng, typename Comp, typename Proj =
hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type make_heap(
```

Constructs a *max heap* in the range [first, last).

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

`bool comp(const Type &a, const Type &b);`

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Proj =
hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type make_heap(ExPolicy &&policy, Iter
first, Sent last, Proj
&&proj = Proj{})
```

Constructs a *max heap* in the range [first, last).

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type make_heap(
```

Constructs a *max heap* in the range [first, last).

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```
template<typename Iter, typename Sent, typename Comp, typename Proj =  
    hpx::parallel::util::projection_identity>  
Iter make_heap(Iter first, Sent last, Comp &&comp, Proj &&proj = Proj{ })
```

Constructs a *max heap* in the range [first, last).

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

`bool comp(const Type &a, const Type &b);`

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *make\_heap* algorithm returns *Iter*. It returns *last*.

```
template<typename Rng, typename Comp, typename Proj = hpx::parallel::util::projection_identity>  
hpx::traits::range_iterator<Rng>::type make_heap(Rng &&rng, Comp &&comp, Proj &&proj =  
    Proj{ })
```

Constructs a *max heap* in the range [first, last).

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

`bool comp(const Type &a, const Type &b);`

The signature does not need to have `const &`, but the function must not modify the objects

passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *make\_heap* algorithm returns *Iter*. It returns *last*.

---

```
template<typename Iter, typename Sent, typename Proj = hpx::parallel::util::projection_identity>
Iter make_heap(Iter first, Sent last, Proj &&proj = Proj{})
```

Constructs a *max heap* in the range [first, last).

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

#### Template Parameters

- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter1*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *make\_heap* algorithm returns *Iter*. It returns *last*.

---

```
template<typename Rng, typename Proj = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng>::type make_heap(Rng &&rng, Proj &&proj = Proj{})
```

Constructs a *max heap* in the range [first, last).

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *make\_heap* algorithm returns *Iter*. It returns *last*.

## hpx/parallel/container\_algorithms/merge.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Comp =
    hpx::ranges::less, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =
    hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::merge_result<typename hpx::traits::range_iterator<Rng1>, typename hpx::traits::range_iterator<Rng2>, Iter3, Comp, Proj1, Proj2>>
```

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)})$  applications of the comparison *comp* and the each projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first range of elements the algorithm will be applied to.
- **rng2** – Refers to the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *Iter1* and *Iter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison *comp* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison *comp* is invoked.

**Returns** The *merge* algorithm returns a `hpx::future<merge_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<Iter1, Iter2, Iter3>` otherwise. The *merge* algorithm returns the tuple of the source iterator *last1*, the source iterator *last2*, the destination iterator to the end of the *dest* range.

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
        typename Iter3, typename Comp = hpx::ranges::less, typename Proj1 =
        hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::merge_result<Iter1, Iter2, Iter3>>::type merge(ExPolicy  
    &&policy,  
    Iter1  
    first1,  
    Sent1  
    last1,  
    Iter2  
    first2,  
    Sent2  
    last2,  
    Iter3  
    dest,  
    Comp  
    &&comp  
    =  
    Comp(),  
    Proj1  
    &&proj  
    =  
    Proj1(),  
    Proj2  
    &&proj  
    =  
    Proj2())
```

Merges two sorted ranges  $[first1, last1]$  and  $[first2, last2]$  into one sorted range beginning at  $dest$ . The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(first1, last1) + \text{std}::\text{distance}(first2, last2))$  applications of the comparison *comp* and the each projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.

- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>
- **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *Iter1* and *Iter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison *comp* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison *comp* is invoked.

**Returns** The *merge* algorithm returns a *hpx::future<merge\_result<Iter1, Iter2, Iter3>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *merge\_result<Iter1, Iter2, Iter3>* otherwise. The *merge* algorithm returns the tuple of the source iterator *last1*, the source iterator *last2*, the destination iterator to the end of the *dest* range.

```
template<typename Rng1, typename Rng2, typename Iter3, typename Comp = hpx::ranges::less,
typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =
hpx::parallel::util::projection_identity>
```

`hpx::ranges::merge_result<typename hpx::traits::range_iterator<Rng1>::type, typename hpx::traits::range_iterator<Rng2>::type, Proj1, Proj2>`

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

---

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(\text{first1}, \text{last1}) + \text{std}::\text{distance}(\text{first2}, \text{last2}))$  applications of the comparison *comp* and the each projection.

---

#### Template Parameters

- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to `util::projection_identity`

#### Parameters

- **rng1** – Refers to the first range of elements the algorithm will be applied to.
- **rng2** – Refers to the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *Iter1* and *Iter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the

elements of the first range as a projection operation before the actual comparison *comp* is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison *comp* is invoked.

**Returns** The *merge* algorithm returns *merge\_result<Iter1, Iter2, Iter3>*. The *merge* algorithm returns the tuple of the source iterator *last1*, the source iterator *last2*, the destination iterator to the end of the *dest* range.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
typename Comp = hpx::ranges::less, typename Proj1 = hpx::parallel::util::projection_identity, typename
Proj2 = hpx::parallel::util::projection_identity>
hpx::ranges::merge_result<Iter1, Iter2, Iter3> merge(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2,
                                                     Iter3 dest, Comp &&comp = Comp(), Proj1
                                                     &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Merges two sorted ranges [`first1`, `last1`] and [`first2`, `last2`] into one sorted range beginning at `dest`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(\text{first1}, \text{last1}) + \text{std}::\text{distance}(\text{first2}, \text{last2}))$  applications of the comparison *comp* and the each projection.

## Template Parameters

- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an random access iterator.
  - **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
  - **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
  - **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
  - **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
  - **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *Copy-Constructible*. This defaults to std::less<>
  - **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to *util::projection\_identity*
  - **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to *util::projection\_identity*

## Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
  - **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
  - **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
  - **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
  - **dest** – Refers to the beginning of the destination range.
  - **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter1` and `Iter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

**Returns** The `merge` algorithm returns `merge_result<Iter1, Iter2, Iter3>`. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```
template<typename ExPolicy, typename Rng, typename Iter, typename Comp = hpx::ranges::less,
typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type inplace_merge(ExPolicy &&policy,
Rng &&rng, Iter
middle, Comp
&&comp = Comp(),
Proj &&proj =
Proj())
```

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(\text{first}, \text{last}))$  applications of the comparison `comp` and the each projection.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the range of elements the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *Iter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *inplace\_merge* algorithm returns a `hpx::future<Iter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *Iter* otherwise. The *inplace\_merge* algorithm returns the source iterator *last*

```
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = hpx::ranges::less,
typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type inplace_merge(ExPolicy &&policy,
Iter first, Iter middle,
Sent last, Comp
&&comp = Comp(),
Proj &&proj =
Proj())
```

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel *inplace\_merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *inplace\_merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(\text{first}, \text{last}))$  applications of the comparison *comp* and the each projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter1*.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace\_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

**Returns** The `inplace_merge` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. The `inplace_merge` algorithm returns the source iterator `last`

```
template<typename Rng, typename Iter, typename Comp = hpx::ranges::less, typename Proj = hpx::parallel::util::projection_identity>
Iter inplace_merge(Rng &&rng, Iter middle, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

---

**Note:** Complexity: Performs  $O(\text{std}::\text{distance}(\text{first}, \text{last}))$  applications of the comparison `comp` and the each projection.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **rng** – Refers to the range of elements the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter` can be

dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *inplace\_merge* algorithm returns *Iter*. The *inplace\_merge* algorithm returns the source iterator *last*

```
template<typename Iter, typename Sent, typename Comp = hpx::ranges::less, typename Proj = hpx::parallel::util::projection_identity>
```

```
Iter inplace_merge(Iter first, Iter middle, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

---

**Note:** Complexity: Performs O(std::distance(first, last)) applications of the comparison *comp* and the each projection.

---

#### Template Parameters

- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for *Iter1*.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace\_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>
- **Proj** – The type of an optional projection function. This defaults to util::projection\_identity

#### Parameters

- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *Iter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *inplace\_merge* algorithm *Iter*. The *inplace\_merge* algorithm returns the source iterator *last*

## hpx/parallel/container\_algorithms/minmax.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Sent, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identityFwdIter min_element(FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for **FwdIter**.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *min\_element* algorithm returns *FwdIter*. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename Rng, typename F = hpx::parallel::v1::detail::less, typename Proj =  

hpx::parallel::util::projection_identity>  

hpx::traits::range_iterator_t<Rng> min_element(Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly *max(N-1, 0)* comparisons, where *N* = *std::distance(first, last)*.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The *min\_element* algorithm returns a *hpx::traits::range\_iterator<Rng>::type* otherwise. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F =  

hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>  

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> min_element(ExPolicy &&policy, FwdIter  

first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *min\_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename Rng, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>> min_element(ExPolicy
    &&policy,
    Rng
    &&rng,
    F
    &&f
    =
    F(),
    Proj
    &&proj
    =
    Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *min\_element* algorithm returns a *hpx::future<hpx::traits::range\_iterator<Rng>::type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename FwdIter, typename Sent, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
FwdIter max_element(FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *max\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly *max(N-1, 0)* comparisons, where *N* = std::distance(first, last).

---

### Template Parameters

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *max\_element* algorithm returns a *FwdIter*. The *max\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename Rng, typename F = hpx::parallel::v1::detail::less, typename Proj =  

hpx::parallel::util::projection_identity>  

hpx::traits::range_iterator_t<Rng> max_element(Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *max\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly *max(N-1, 0)* comparisons, where *N* = *std::distance(first, last)*.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *max\_element* algorithm returns a *hpx::traits::range\_iterator<Rng>::type* otherwise. The *max\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F =  

hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>  

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> max_element(ExPolicy &&policy, FwdIter  

first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *max\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the This argument is optional and defaults to *std::less*. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *max\_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *max\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename Rng, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>> max_element(ExPolicy
    &&policy,
    Rng
    &&rng,
    F
    &&f
    =
    F(),
    Proj
    &&proj
    =
    Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *max\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the This argument is optional and defaults to `std::less`. The left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *max\_element* algorithm returns a *hpx::future<hpx::traits::range\_iterator<Rng>::type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *max\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename FwdIter, typename Sent, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
minmax_element_result<FwdIter> minmax_element(FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The assignments in the parallel *minmax\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: At most *max(floor(3/2\*(N-1)), 0)* applications of the predicate, where N = *std::distance(first, last)*.

---

### Template Parameters

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to *std::less*. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *minmax\_element* algorithm returns a *minmax\_element\_result<FwdIter, FwdIter>*. The *minmax\_element* algorithm returns a *min\_max\_result* consisting of an iterator to the smallest element as the min element and an iterator to the greatest element as the max element. Returns *minmax\_element\_result{first, first}* if the range is empty. If several elements are

equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```
template<typename Rng, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
minmax_element_result<hpx::traits::range_iterator_t<Rng>> minmax_element(Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The assignments in the parallel *minmax\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to *std::less*. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have *const &*, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *minmax\_element* algorithm returns a *minmax\_element\_result<hpx::traits::range\_iterator<Rng>::type>*, *hpx::traits::range\_iterator<Rng>::type*. The *minmax\_element* algorithm returns a *min\_max\_result* consisting of an range iterator to the smallest element as the min element and an range iterator to the greatest element as the max element. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
```

```
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, minmax_element_result<FwdIter>> minmax_element(ExPolicy
    &&policy,
    FwdIter
    first,
    Sent
    last,
    F
    &&f
    =
    F(),
    Proj
    &&proj
    =
    Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *minmax\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *minmax\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `minmax_element` algorithm returns a `minmax_element_result<FwdIter, FwdIter>`

The `minmax_element` algorithm returns a `min_max_result` consisting of an iterator to the smallest element as the min element and an iterator to the greatest element as the max element. Returns `minmax_element_result{first, first}` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```
template<typename ExPolicy, typename Rng, typename F = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::algorithm_result_t<ExPolicy, minmax_element_result<hpx::traits::range_iterator_t<Rng>>> minmax_element
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std::distance(first, last)}$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *minmax\_element* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The *minmax\_element* algorithm returns a *minmax\_element\_result<hpx::traits::range\_iterator<Rng>::type, hpx::traits::range\_iterator<Rng>::type>*. The *minmax\_element* algorithm returns a *min\_max\_result* consisting of an range iterator to the smallest element as the min element and an range iterator to the greatest element as the max element. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

## hpx/parallel/container\_algorithms/mismatch.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
         typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =
         hpx::parallel::util::projection_identity>
```

---

```

hpx::parallel::util::detail::algorithm_result<ExPolicy, mismatch_result<Iter1, Iter2>>::type mismatch(ExPolicy
    &&policy,
    Iter1
    first1,
    Sent1
    last1,
    Iter2
    first2,
    Sent2
    last2,
    Pred
    &&op
    =
    Pred(),
    Proj1
    &&proj1
    =
    Proj1(),
    Proj2
    &&proj2
    =
    Proj2())

```

Returns true if the range [first1, last1) is mismatch to the range [first2, last2), and false otherwise.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate  $f$ . If  $\text{FwdIter1}$  and  $\text{FwdIter2}$  meet the requirements of *RandomAccessIterator* and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no applications of the predicate  $f$  are made.

---

**Note:** The two ranges are considered mismatch if, for every iterator  $i$  in the range  $[\text{first1}, \text{last1})$ ,  $*i \neq *(\text{first2} + (i - \text{first1}))$ . This overload of mismatch uses operator $\==$  to determine if two elements are mismatch.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *mismatch* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `bool` otherwise. The *mismatch* algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range  $[first1, last1]$  does not mismatch the length of the range  $[first2, last2]$ , it returns false.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
```

---

`hpx::parallel::util::detail::algorithm_result<ExPolicy, mismatch_result<typename hpx::traits::range_traits<Rng1>::iterator_`

Returns std::pair with iterators to the first two non-equivalent elements.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *f*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1, FwdIter2>` otherwise. The *mismatch* algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2)`.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
mismatch_result<Iter1, Iter2> mismatch(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range `[first1, last1)` is mismatch to the range `[first2, last2)`, and false otherwise.

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate *f*. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no applications of the predicate *f* are made.

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range `[first1, last1)`,  $*i$  mismatch  $*(\text{first2} + (\text{i} - \text{first1}))$ . This overload of *mismatch* uses operator`==` to determine if two elements are mismatch.

---

#### Template Parameters

- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *mismatch* algorithm returns `bool`. The *mismatch* algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range `[first1, last1]` does not mismatch the length of the range `[first2, last2]`, it returns false.

```
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 =
    hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
mismatch_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type>
```

Returns `std::pair` with iterators to the first two non-equivalent elements.

---

**Note:** Complexity: At most `last1 - first1` applications of the predicate *f*.

---

#### Template Parameters

- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This

- defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

**Parameters**

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns** The *mismatch* algorithm returns `std::pair<FwdIter1, FwdIter2>`. The *mismatch* algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1]` and another defined by `[first2, last2]`.

## hpx/parallel/container\_algorithms/move.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, move_result<Iter1, Iter2>>::type move(ExPolicy
    &&policy,
    Iter1 first,
    Sent1 last,
    Iter2 dest)
```

Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *move* algorithm returns a `hpx::future<ranges::move_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `ranges::move_result<iterator_t<Rng>, FwdIter2>` otherwise. The *move* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename Rng, typename Iter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, move_result<typename hpx::traits::range_iterator<Rng>::type, Iter2>>
```

Moves the elements in the range *rng* to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *move* algorithm returns a `hpx::future<ranges::move_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::move_result<iterator_t<Rng>, FwdIter2>` otherwise. The *move* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename Iter1, typename Sent1, typename Iter2>
move_result<Iter1, Iter2> move(Iter1 first, Sent1 last, Iter2 dest)
```

Moves the elements in the range *rng* to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

---

**Note:** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

---

**Template Parameters**

- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *move* algorithm returns `ranges::move_result<iterator_t<Rng>, FwdIter2>`. The *move* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename Rng, typename Iter2>
move_result<typename hpx::traits::range_iterator<Rng>::type, Iter2> move(Rng &&rng, Iter2 dest)
```

Moves the elements in the range *rng* to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

---

**Note:** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The *move* algorithm returns a `ranges::move_result<iterator_t<Rng>, FwdIter2>`.

The *move* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element moved.

## hpx/parallel/container\_algorithms/nth\_element.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename RandomIt, typename Sent, typename Pred, typename Proj>
RandomIt nth_element(RandomIt first, RandomIt nth, Sent last, Pred &&pred, Proj &&proj)
```

*nth\_element* is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by *nth* is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element.

The comparison operations in the parallel *nth\_element* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

---

#### Template Parameters

- **RandomIt** – The type of the source begin, *nth*, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *RandomIt*.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

<b>bool cmp(const Type1 &amp;a, const Type2 &amp;b);</b>
--

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to *Type*. This defaults to `std::less<>`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. This defaults to `projection_identity`.

**Returns** The `nth_element` algorithm returns *RandomIt*. The `nth_element` algorithm returns an iterator equal to *last*.

```
template<typename ExPolicy, typename RandomIt, typename Sent, typename Pred, typename Proj>
parallel::util::detail::algorithm_result_t<ExPolicy, RandomIt> nth_element(ExPolicy &&policy,
                                         RandomIt first, RandomIt
                                         nth, Sent last, Pred
                                         &&pred, Proj &&proj)
```

`nth_element` is a partial sorting algorithm that rearranges elements in  $[first, last]$  such that the element pointed at by *nth* is changed to whatever element would occur in that position if  $[first, last]$  were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element.

The comparison operations in the parallel `nth_element` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `nth_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in `std::distance(first, last)` on average.  $O(N)$  applications of the predicate, and  $O(N \log N)$  swaps, where  $N = last - first$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source begin, *nth*, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `RandomIt`.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type must be such that an object of type `randomIt` can be dereferenced

and then implicitly converted to Type. This defaults to std::less<>.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. This defaults to projection\_identity.

**Returns** The *partition* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *parallel\_task\_policy* and returns *RandomIt* otherwise. The *nth\_element* algorithm returns an iterator equal to last.

```
template<typename Rng, typename Pred, typename Proj>
hpx::traits::range_iterator_t<Rng> nth_element(Rng &&rng, hpx::traits::range_iterator_t<Rng> nth,
                                                Pred &&pred, Proj &&proj)
```

*nth\_element* is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by *nth* is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element.

The comparison operations in the parallel *nth\_element* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. This defaults to projection\_identity.

**Returns** The *nth\_element* algorithm returns returns *hpx::traits::range\_iterator\_t<Rng>*. The *nth\_element* algorithm returns an iterator equal to last.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj>
```

```
parallel::util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>> nth_element(ExPolicy
&&policy,
Rng
&&rng,
hpx::traits::range_it
nth,
Pred
&&pred,
Proj
&&proj)
```

*nth\_element* is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by *nth* is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element.

The comparison operations in the parallel *nth\_element* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. This defaults to *projection\_identity*.

**Returns** The *partition* algorithm returns a `hpx::future<hpx::traits::range_iterator_t<Rng>>` if the execution policy is of type `parallel_task_policy` and returns `hpx::traits::range_iterator_t<Rng>` otherwise. The *nth\_element* algorithm returns an iterator equal to last.

## hpx/parallel/container\_algorithms/partial\_sort.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

template<typename **RandomIt**, typename **Sent**, typename **Comp**, typename **Proj**>  
`RandomIt partial_sort(RandomIt first, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())`

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

The assignments in the parallel *partial\_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Approximately (last - first) \* log(middle - first) comparisons.

---

#### Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. Comp defaults to `detail::less`.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *partial\_sort* algorithm returns *RandomIt*. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```
template<typename ExPolicy, typename RandomIt, typename Sent, typename Comp, typename Proj>
parallel::util::detail::algorithm_result_t<ExPolicy, RandomIt> partial_sort(ExPolicy &&policy,
                                         RandomIt first,
                                         RandomIt middle, Sent
                                         last, Comp &&comp =
                                         Comp(), Proj &&proj =
                                         Proj())
```

Places the first *middle - first* elements from the range [*first*, *last*] as sorted with respect to *comp* into the range [*first*, *middle*). The rest of the elements in the range [*middle*, *last*] are placed in an unspecified order.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Approximately (*last - first*) \* log(*middle - first*) comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *RandomIt*.
- **Comp** – The type of the function/function object to use (deduced). *Comp* defaults to *detail::less*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to *bool*, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator. *Comp* defaults to *detail::less*.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *partial\_sort* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandomIt* otherwise.

The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```
template<typename Rng, typename Comp,
typename Proj> hpx::traits::range_iterator_t< Rng > partial_sort (Rng &&rng,,  
hpx::traits::range_iterator_t< Rng > middle, Comp &&comp=Comp(),  
Proj &&proj=Proj())
```

Places the first `middle - first` elements from the range `[first, last)` as sorted with respect to `comp` into the range `[first, middle)`. The rest of the elements in the range `[middle, last)` are placed in an unspecified order.

The assignments in the parallel `partial_sort` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Approximately  $(last - first) * \log(middle - first)$  comparisons.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced). `Comp` defaults to `detail::less`.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator. `Comp` defaults to `detail::less`.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `partial_sort` algorithm returns `typename hpx::traits::range_iterator_t<Rng>`. It returns `last`.

```
template<typename ExPolicy, typename Rng, typename Comp, typename Proj>  
util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>> partial_sort(ExPolicy  
&&pol-  
ic平, Rng  
&&rng,  
hpx::traits::range_iterator_t<  
middle,  
Comp  
&&comp  
= Comp(),  
Proj  
&&proj =  
Proj())
```

Sorts the elements in the range `[first, last)` in ascending order. The relative order of equal elements

is preserved. The function uses the given comparison function object `comp` (defaults to using operator`<()`).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.`

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced). `Comp` defaults to `detail::less;`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator. `Comp` defaults to `detail::less`.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `partial_sort` algorithm returns a `hpx::future<typename hpx::traits::range_iterator_t<Rng>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `typename hpx::traits::range_iterator_t<Rng>` otherwise. It returns `last`.

## hpx/parallel/container\_algorithms/partial\_sort\_copy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent1, typename RandIter, typename Sent2, typename Comp,
typename Proj1, typename Proj2>
partial_sort_copy_result<InIter, RandIter> partial_sort_copy(InIter first, Sent1 last, RandIter
d_first, Sent2 d_last, Comp &&comp
= Comp(), Proj1 &&proj1 = Proj1(),
Proj2 &&proj2 = Proj2())
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d\_first, d\_last). At most d\_last - d\_first of the elements are placed sorted to the range [d\_first, d\_first + n) where n is the number of elements to sort (n = min(last - first, d\_last - d\_first)).

The assignments in the parallel *partial\_sort\_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(\min(D, N)))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  and  $D = \text{std}::\text{distance}(d_{\text{first}}, d_{\text{last}})$  comparisons.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **RandIter** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent2** – The type of the destination sentinel (deduced). This sentinel type must be a sentinel for RandIter.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `util::projection_identity`.
- **Proj1** – The type of an optional projection function for the output range. This defaults to `util::projection_identity`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the sentinel value denoting the end of the sequence of elements the algorithm will be applied to.
- **d\_first** – Refers to the beginning of the destination range.
- **d\_last** – Refers to the sentinel denoting the end of the destination range.

- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.
- **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate *comp* is invoked.

**Returns** The *partial\_sort\_copy* algorithm returns a returns *partial\_sort\_copy\_result*<*InIter*, *RandIter*>. The algorithm returns {last, result\_first + N}.

```
template<typename ExPolicy, typename FwdIter, typename Sent1, typename RandIter, typename  
Sent2, typename Comp, typename Proj1, typename Proj2>
```

```
parallel::util::detail::algorithm_result_t<ExPolicy, partial_sort_copy_result<FwdIter, RandIter>> partial_sort_copy(E
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d\_first, d\_last). At most d\_last - d\_first of the elements are placed sorted to the range [d\_first, d\_first + n) where n is the number of elements to sort (n = min(last - first, d\_last - d\_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(Nlog(min(D,N))), where N = std::distance(first, last) and D = std::distance(d\_first, d\_last) comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source sentinel (deduced).This sentinel type must be a sentinel for FwdIter.
- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Sent2** – The type of the destination sentinel (deduced).This sentinel type must be a sentinel for RandIter.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `util::projection_identity`.
- **Proj2** – The type of an optional projection function for the output range. This defaults to `util::projection_identity`.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the sentinel value denoting the end of the sequence of elements the algorithm will be applied to.
- **d\_first** – Refers to the beginning of the destination range.
- **d\_last** – Refers to the sentinel denoting the end of the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to `detail::less`.
- **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate `comp` is invoked.

**Returns** The `partial_sort_copy` algorithm returns a `hpx::future<partial_sort_copy_result<FwdIter, RandIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `partial_sort_copy_result<FwdIter, RandIter>` otherwise. The algorithm returns `{last, result_first + N}`.

template<typename **ExPolicy**, typename **FwdIter**, typename **Sent1**, typename **RandIter**, typename **Sent2**, typename **Comp**, typename **Proj1**, typename **Proj2**>

partial\_sort\_copy\_result<*hpx::traits*::range\_iterator\_t<Rng1>, *hpx::traits*::range\_iterator\_t<Rng2>> **partial\_sort\_copy**

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d\_first, d\_last). At most d\_last - d\_first of the elements are placed sorted to the range [d\_first, d\_first + n) where n is the number of elements to sort (n = min(last - first, d\_last - d\_first)).

The assignments in the parallel *partial\_sort\_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(\min(D, N)))$ , where  $N = \text{std}::distance(first, last)$  and  $D = \text{std}::distance(d\_first, d\_last)$  comparisons.

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of a random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `util::projection_identity`.
- **Proj1** – The type of an optional projection function for the output range. This defaults to `util::projection_identity`.

#### Parameters

- **rng1** – Refers to the source range.
- **rng1** – Refers to the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to `detail::less`.
- **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate *comp* is invoked.

**Returns** The *partial\_sort\_copy* algorithm returns *partial\_sort\_copy\_result<range\_iterator\_t<Rng1>, range\_iterator\_t<Rng2>>*. The algorithm returns {last, result\_first + N}.

---

```
template<typename ExPolicy, typename FwdIter, typename Sent1, typename RandIter, typename
Sent2, typename Comp, typename Proj1, typename Proj2parallel::util::detail::algorithm_result_t<ExPolicy, partial_sort_copy_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d\_first, d\_last). At most d\_last - d\_first of the elements are placed sorted to the range [d\_first, d\_first + n) where n is the number of elements to sort (n = min(last - first, d\_last - d\_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(\min(D, N)))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  and  $D = \text{std}::\text{distance}(d_{\text{first}}, d_{\text{last}})$  comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of a random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `util::projection_identity`.
- **Proj2** – The type of an optional projection function for the output range. This defaults to `util::projection_identity`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the source range.

- **rng1** – Refers to the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.
- **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate *comp* is invoked.

**Returns** The *partial\_sort\_copy* algorithm returns a *hpx::future<partial\_sort\_copy\_result<range\_iterator\_t<Rng1>, range\_iterator\_t<Rng2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *partial\_sort\_copy\_result<range\_iterator\_t<Rng1>, range\_iterator\_t<Rng2>>* otherwise. The algorithm returns {last, result\_first + N}.

## hpx/parallel/container\_algorithms/partition.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent, typename Pred, typename Proj>
subrange_t<FwdIter> partition(ExPolicy &&policy, Sent first, Sent last, Pred &&pred, Proj &&proj)
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $2 * (\text{last} - \text{first})$  swaps. Exactly  $\text{last} - \text{first}$  applications of the predicate and projection.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition* algorithm returns *subrange\_t<FwdIter>*. The *partition* algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to *last*.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred, typename Proj>
util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter>>::type partition(ExPolicy &&policy,
FwdIter first, Sent last,
Pred &&pred, Proj
&&proj)
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * (\text{last} - \text{first})$  swaps. Exactly  $\text{last} - \text{first}$  applications of the predicate and projection.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter`.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition* algorithm returns a *hpx::future<subrange\_t<FwdIter>>* if the execution policy is of type *parallel\_task\_policy* and returns *subrange\_t<FwdIter>* otherwise. The *partition* algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to *last*.

```
template<typename Rng, typename Pred, typename Proj>
subrange_t<hpx::traits::range_iterator_t<Rng>> partition(Rng &&rng, Pred &&pred, Proj &&proj)
```

Reorders the elements in the range *rng* in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs at most  $2 * N$  swaps, exactly  $N$  applications of the predicate and projection, where  $N = \text{std}::\text{distance}(\text{begin}(\text{rng}), \text{end}(\text{rng}))$ .

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range *rng*. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition* algorithm returns *subrange\_t<hpx::traits::range\_iterator\_t<Rng>>*.  
 The *partition* algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to last.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj>
util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>>>::type partition(ExPolicy
&&policy,
Rng
&&rng,
Pred
&&pred,
Proj
&&proj)
```

Reorders the elements in the range *rng* in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs at most  $2 * N$  swaps, exactly  $N$  applications of the predicate and projection, where  $N = \text{std}:\text{distance}(\text{begin}(\text{rng}), \text{end}(\text{rng}))$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range *rng*. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition* algorithm returns a `hpx::future<subrange_t<hpx::traits::range_iterator_t<Rng>>>` if the execution policy is of type `parallel_task_policy` and returns `subrange_t<hpx::traits::range_iterator_t<Rng>>` The *partition* algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to last.

```
template<typename BidirIter, typename Sent, typename F, typename Proj>
subrange_t<BidirIter> stable_partition(BidirIter first, Sent last, F &&f, Proj &&proj)
```

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator k in the range [i, last), `INVOKE(f, INVOKE(proj, *k)) == false`

The invocations of *f* in the parallel *stable\_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) * \log(\text{last} - \text{first})$  swaps, but only linear number of swaps if there is enough extra memory Exactly *last - first* applications of the predicate and projection.

---

#### Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for BidirIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *stable\_partition* algorithm returns an iterator *i* such that for every iterator *j* in the range [first, *i*), `f(*j) != false` `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator *k* in the range [*i*, last), `f(*k) == false` `INVOKE(f, INVOKE(proj, *k)) == false`. The relative order of the elements in both groups is preserved.

```
template<typename ExPolicy, typename BidirIter, typename Sent, typename F, typename Proj>
```

```
util::detail::algorithm_result<ExPolicy, subrange_t<BidirIter>>::type stable_partition(ExPolicy
&&policy,
BidirIter
first, Sent
last, F &&f,
Proj
&&proj)
```

Permutes the elements in the range [*first*, *last*] such that there exists an iterator *i* such that for every iterator *j* in the range [*first*, *i*] *INVOKE*(*f*, *INVOKE* (*proj*, \**j*)) != false, and for every iterator *k* in the range [*i*, *last*], *INVOKE*(*f*, *INVOKE* (*proj*, \**k*)) == false

The invocations of *f* in the parallel *stable\_partition* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The invocations of *f* in the parallel *stable\_partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (*last* - *first*) \* log(*last* - *first*) swaps, but only linear number of swaps if there is enough extra memory Exactly *last* - *first* applications of the predicate and projection.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *BidirIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [*first*, *last*). The signature of this predicate should be equivalent to:

<code>bool fun(const Type &amp;a);</code>
---

The signature does not need to have `const&`. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *stable\_partition* algorithm returns an iterator *i* such that for every iterator *j* in

the range [first, i),  $f(*j) \neq \text{false}$   $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}$ , and for every iterator k in the range [i, last),  $f(*k) == \text{false}$   $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) == \text{false}$ . The relative order of the elements in both groups is preserved. If the execution policy is of type *parallel\_task\_policy* the algorithm returns a future<> referring to this iterator.

```
template<typename Rng, typename F, typename Proj>
subrange_t<hpx::traits::range_iterator_t<Rng>> stable_partition(Rng &&rng, F &&f, Proj &&proj)
```

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i)  $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}$ , and for every iterator k in the range [i, last),  $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) == \text{false}$

The invocations of *f* in the parallel *stable\_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) * \log(\text{last} - \text{first})$  swaps, but only linear number of swaps if there is enough extra memory Exactly *last - first* applications of the predicate and projection.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an bidirectional iterator
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have *const&*. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *stable\_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i),  $f(*j) \neq \text{false}$   $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}$ , and for every iterator k in the range [i, last),  $f(*k) == \text{false}$   $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) == \text{false}$ . The relative order of the elements in both groups is preserved.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj>
util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>>>::type stable_partition(ExPolicy &&po
```

icy,  
Rng &&rn  
F &&f,  
Proj &&pr

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i)  $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}$ , and for every iterator k in the range [i, last),  $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) = \text{false}$

The invocations of  $f$  in the parallel *stable\_partition* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The invocations of  $f$  in the parallel *stable\_partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) * \log(\text{last} - \text{first})$  swaps, but only linear number of swaps if there is enough extra memory. Exactly  $\text{last} - \text{first}$  applications of the predicate and projection.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of  $f$ .
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an bidirectional iterator
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires  $F$  to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate  $f$  is invoked.

**Returns** The *stable\_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i),  $f(*j) \neq \text{false}$   $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}$ , and for every iterator k in the range [i, last),  $f(*k) = \text{false}$   $\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) = \text{false}$ . The relative order of the elements in both groups is preserved. If the execution policy is of type *parallel\_task\_policy* the algorithm returns a future<> referring to this iterator.

```
template<typename FwdIter1, typename Sent, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj>
hpx::util::in_out_out<FwdIter1, FwdIter2, FwdIter3> partition_copy(FwdIter1 first, Sent last,
                                                               FwdIter2 dest_true, FwdIter3
                                                               dest_false, Pred &&pred, Proj
                                                               &&proj)
```

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value

returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition\_copy* algorithm returns a *partition\_copy\_result<FwdIter, OutIter2, OutIter3>*. The *partition\_copy* algorithm returns the tuple of the source iterator *last*, the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **Sent**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred**, typename **Proj**>

```
util::detail::algorithm_result<ExPolicy, partition_copy_result<FwdIter, OutIter2, OutIter3>>::type partition_copy(ExPolicy&&  
&&  
icy,  
FwdI  
first,  
Sent  
last,  
FwdI  
dest_  
FwdI  
dest_  
Pred  
&&  
Proj  
&&
```

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied

- to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
  - **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
  - **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
  - **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition\_copy* algorithm returns a `hpx::future<partition_copy_result<FwdIter, OutIter2, OutIter3>>` if the execution policy is of type *parallel\_task\_policy* and returns *partition\_copy\_result<FwdIter, OutIter2, OutIter3>* otherwise. The *partition\_copy* algorithm returns the tuple of the source iterator *last*, the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

```
template<typename Rng, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj>
partition_copy_result<hpx::traits::range_iterator_t<Rng>, FwdIter2, FwdIter3>::type partition_copy(Rng
&&rng,
FwdIter2
dest_true,
FwdIter3
dest_false,
Pred
&&pred,
Proj
&&proj)
```

Copies the elements in the range *rng*, to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than N assignments, exactly N applications of the predicate *pred*, where N = std::distance(begin(rng), end(rng)).

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition\_copy* algorithm returns a partitioning *partition\_copy\_result<hpx::traits::range\_iterator\_t<Rng>, FwdIter2, FwdIter3>>*. The *partition\_copy* algorithm returns the tuple of the source iterator *last*, the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

```
template<typename ExPolicy, typename Rng, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj>
parallel::util::detail::algorithm_result<ExPolicy, partition_copy_result<hpx::traits::range_iterator_t<Rng>, FwdIter2, FwdIter3>>
```

Copies the elements in the range *rng*, to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than N assignments, exactly N applications of the predicate *pred*, where N = std::distance(begin(rng), end(rng)).

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *partition\_copy* algorithm returns a *hpx::future<partition\_copy\_result<hpx::traits::range\_iterator\_t<Rng>, FwdIter2, FwdIter3>>* if the execution policy is of type *parallel\_task\_policy* and returns *partition\_copy\_result<hpx::traits::range\_iterator\_t<Rng>, FwdIter2, FwdIter3>* otherwise. The *partition\_copy* algorithm returns the tuple of the source iterator *last*, the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

## `hpx/parallel/container_algorithms/reduce.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename T, typename FExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, Sent last, T
init, F &&f)
```

Returns GENERALIZED\_SUM(f, init, \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *f*.

---

**Note:** GENERALIZED\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as follows:

- *a*<sub>1</sub> when N is 1
  - *op*(GENERALIZED\_SUM(*op*, *b*<sub>1</sub>, ..., *b*<sub>K</sub>), GENERALIZED\_SUM(*op*, *b*<sub>M</sub>, ..., *b*<sub>N</sub>)), where:
    - *b*<sub>1</sub>, ..., *b*<sub>N</sub> may be any permutation of *a*<sub>1</sub>, ..., *a*<sub>N</sub> and
    - $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1` `Ret` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last)`.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename TExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, Sent last, T
init)
```

Returns `GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1))`.

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the operator `+`.

---

---

**Note:** `GENERALIZED_SUM(+, a1, ..., aN)` is defined as follows:

- $a_1$  when  $N$  is 1
- $\text{op}(\text{GENERALIZED\_SUM}(+, b_1, \dots, b_K), \text{GENERALIZED\_SUM}(+, b_M, \dots, b_N))$ , where:
  - $b_1, \dots, b_N$  may be any permutation of  $a_1, \dots, a_N$  and
  - $1 < K+1 = M \leq N$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

**Returns** The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter, typename Sent>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(ExPolicy
    &&policy,
    FwdIter
    first,
    Sent
    last)
```

Returns GENERALIZED\_SUM(+, T(), \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity: O(*last - first*) applications of the operator+().

---

---

**Note:** The type of the initial value (and the result type) *T* is determined from the *value\_type* of the used *FwdIterB*.

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
  - b1, ..., bN may be any permutation of a1, ..., aN and
  - 1 < K+1 = M <= N.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Sent** – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *reduce* algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise (where `T` is the `value_type` of `FwdIterB`). The *reduce* algorithm returns the result of the generalized sum (applying operator`+`()) over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename Rng, typename T, typename F>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, Rng &&rng, T init, F &&f)
```

Returns GENERALIZED\_SUM(f, init, \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *f*.

---

---

**Note:** GENERALIZED\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as follows:

- *a*<sub>1</sub> when *N* is 1
- *op*(GENERALIZED\_SUM(*op*, *b*<sub>1</sub>, ..., *b*<sub>K</sub>), GENERALIZED\_SUM(*op*, *b*<sub>M</sub>, ..., *b*<sub>N</sub>)), where:
  - *b*<sub>1</sub>, ..., *b*<sub>N</sub> may be any permutation of *a*<sub>1</sub>, ..., *a*<sub>N</sub> and
  - $1 < K+1 = M \leq N$ .

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature

of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last]`.

```
template<typename ExPolicy, typename Rng, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, Rng &&rng, T init)
    Returns GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1)).
```

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the operator `+`.

---

**Note:** `GENERALIZED_SUM(+, a1, ..., aN)` is defined as follows:

- $a_1$  when  $N$  is 1
  - $\text{op}(\text{GENERALIZED\_SUM}(+, b_1, \dots, b_K), \text{GENERALIZED\_SUM}(+, b_M, \dots, b_N))$ , where:
    - $b_1, \dots, b_N$  may be any permutation of  $a_1, \dots, a_N$  and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator `+( )`) over the elements given by the input range `[first, last]`.

```
template<typename ExPolicy, typename Rng>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>
```

Returns GENERALIZED\_SUM(+, T(), \*first, ..., \*(first + (last - first) - 1)).

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity: O(*last - first*) applications of the operator+().

---

---

**Note:** The type of the initial value (and the result type) *T* is determined from the *value\_type* of the used *FwdIterB*.

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
  - b1, ..., bN may be any permutation of a1, ..., aN and
  - 1 < K+1 = M <= N.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise (where *T* is the *value\_type* of *FwdIterB*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

## hpx/parallel/container\_algorithms/remove.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent, typename T, typename Proj = util::projection_identity>
subrange_t<FwdIter, Sent> remove(FwdIter first, Sent last, T const &value, Proj &&proj = Proj())
```

Removes all elements that are equal to *value* from the range [first, last) and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the operator==() and the projection *proj*.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The *remove* algorithm returns a *subrange\_t*<*FwdIter*, *Sent*>. The *remove* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename T, typename Proj = util::projection_identity>
```

```
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type remove(ExPolicy
    &&policy,
    FwdIter
    first, Sent
    last, T
    const
    &value,
    Proj
    &&proj =
    Proj())
```

Removes all elements that are equal to *value* from the range [first, last) and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the operator==() and the projection *proj*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *remove* algorithm returns a *hpx::future<subrange\_t<FwdIter, Sent>>*. The *remove* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```
template<typename Rng, typename T, typename Proj = util::projection_identity>
subrange_t<typename hpx::traits::range_iterator<Rng>::type> remove(Rng &&rng, T const &value,
                                                               Proj &&proj = Proj())
```

Removes all elements that are equal to *value* from the range *rng* and returns a subrange [ret, *util::end(rng)*), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *util::end(rng)*

- *util::begin(rng)* assignments, exactly *util::end(rng) - util::begin(rng)* applications of the operator==() and the projection *proj*.
- 

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *remove* algorithm returns a *subrange\_t<typename hpx::traits::range\_iterator<Rng>::type>*. The *remove* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```
template<typename ExPolicy, typename Rng, typename T, typename Proj = util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<typename hpx::traits::range_iterator<Rng>::type>>::type remove
```

Removes all elements that are equal to *value* from the range *rng* and and returns a subrange [ret, *util::end(rng)*), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *util::end(rng)*

- *util::begin(rng)* assignments, exactly *util::end(rng) - util::begin(rng)* applications of the operator==() and the projection *proj*.
-

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *remove* algorithm returns a *hpx::future< subrange\_t<typename hpx::traits::range\_iterator<Rng>::type>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *remove* algorithm returns the iterator to the new end of the range.

```
template<typename FwdIter, typename Sent, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
subrange_t<FwdIter, Sent> remove_if(FwdIter first, Sent sent, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements for which predicate *pred* returns true from the range [first, last) and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred* and the projection *proj*.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

**Returns** The `remove_if` algorithm returns a `subrange_t<FwdIter, Sent>`. The `remove_if` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred, typename Proj =
    hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type remove_if(ExPolicy
    &&policy,
    FwdIter
    first,
    Sent
    sent,
    Pred
    &&pred,
    Proj
    &&proj
    =
    Proj())
```

Removes all elements for which predicate `pred` returns true from the range `[first, last)` and returns a subrange `[ret, last)`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred` and the projection `proj`.

---

### Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **`Sent`** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.
- **`Proj`** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *remove\_if* algorithm returns a *hpx::future<subrange\_t<FwdIter, Sent>>*. The *remove\_if* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```
template<typename Rng, typename T, typename Proj = util::projection_identity>
subrange_t<typename hpx::traits::range_iterator<Rng>::type> remove_if(Rng &&rng, Pred &&pred,
                                                               Proj &&proj = Proj())
```

Removes all elements that are equal to *value* from the range *rng* and returns a subrange [ret, `util::end(rng)`), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than `util::end(rng)`

- `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator`==()` and the projection *proj*.
- 

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *remove\_if* algorithm returns a *subrange\_t<typename hpx::traits::range\_iterator<Rng>::type>*. The *remove\_if* algorithm returns an object

{ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj =  

util::projection_identity>  

parallel::util::detail::algorithm_result<ExPolicy, subrange_t<typename hpx::traits::range_iterator<Rng>::type>>::type remove_if
```

Removes all elements that are equal to *value* from the range *rng* and returns a subrange [ret, util::end(rng)), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel *remove\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *util::end(rng)*

- *util::begin(rng)* assignments, exactly *util::end(rng) - util::begin(rng)* applications of the operator==() and the projection *proj*.
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

<b>bool pred(const Type &amp;a);</b>
--------------------------------------

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *remove\_if* algorithm returns a `hpx::future<subrange_t< typename hpx::traits::range_iterator<Rng>::type>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *remove\_if* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename Iter, typename Sent, typename T1, typename T2, typename Proj =  
        hpx::parallel::util::projection_identity>  
Iter replace(Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())  
    Replaces all elements satisfying specific criteria with new_value in the range [first, last).
```

Effects: Substitutes elements referred by the iterator it in the range [first,last) with new\_value, when the following corresponding conditions hold: `INVOKED(proj, *i) == old_value`

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).

- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace* algorithm returns an *Iter*.

```
template<typename Rng, typename T1, typename T2, typename Proj =
    hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng>::type replace(Rng &&rng, T1 const &old_value, T2 const
&new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: `(INVOKE(proj, *i) == old_value)`

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` assignments.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace* algorithm returns an *hpx::traits::range\_iterator<Rng>::type*.

```
template<typename ExPolicy, typename Iter, typename Sent, typename T1, typename T2, typename Proj =
    hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, Iter>::type replace(ExPolicy &&policy, Iter first, Sent
sent, T1 const &old_value, T2 const &new_value, Proj &&proj
= Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator *it* in the range [first, last) with *new\_value*, when the following corresponding conditions hold: `(INVOKE(proj, *i) == old_value)`

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace* algorithm returns a *hpx::future<Iter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *Iter* otherwise.

```
template<typename ExPolicy, typename Rng, typename T1, typename T2, typename Proj =  
        hpx::parallel::util::projection_identity>  
parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type replace(ExPolicy  
&&policy,  
Rng &&rng,  
T1  
const  
&old_v  
T2  
const  
&new_v  
Proj  
&&proj  
=  
Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKED(proj, *i) == old_value`

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` is invoked. The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Returns** The `replace` algorithm returns an `hpx::future<hpx::traits::range_iterator<Rng>::type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `hpx::traits::range_iterator<Rng>::type` otherwise.

```
template<typename Iter, typename Sent, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
Iter replace_if(Iter first, Sent sent, Pred &&pred, T const &new_value, Proj &&proj = Proj())
    Replaces all elements satisfying specific criteria (for which predicate f returns true) with new_value in the range [first, sent].
```

Effects: Substitutes elements referred by the iterator `it` in the range `[first, sent)` with `new_value`, when the following corresponding conditions hold: `INVOKED(f, INVOKED(proj, *it)) != false`

The assignments in the parallel `replace_if` algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly `sent - first` applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace\_if* algorithm returns an *Iter*. It returns *last*.

```
template<typename Rng, typename Pred, typename T, typename Proj =  
hpx::parallel::util::projection_identity>  
hpx::traits::range_iterator<Rng>::type replace_if(Rng &&rng, Pred &&pred, T const &new_value,  
Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate *pred* returns *true*) with *new\_value* in the range *rng*.

**Effects:** Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: *(INVOKE(f, INVOKE(proj, \*it)) != false)*

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* applications of the predicate.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *rng*. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace\_if* algorithm returns an *hpx::traits::range\_iterator<Rng>::type* It returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Pred,
typename T,
typename Proj = hpx::parallel::util::projection_identity> parallel::util::detail::algorithm_result<
Iter >::type t_replace_if (ExPolicy &&policy, Iter first, Sent sent,
Pred &&pred, T const &new_value, Proj &&proj=Proj())
```

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new\_value* in the range *rng*.

**Effects:** Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: *(INVOKE(f, INVOKE(proj, \*it)) != false)*

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* applications of the predicate.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.

- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns `true` for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `replace_if` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy`. It returns `last`.

```
template<typename ExPolicy, typename Rng, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type replace_if(ExPolicy
&& icy,
Rng && Pre
&& & & Proj
&& & & Proj
T
con
&ne
Proj
&& =
Proj
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `rng`.

**Effects:** Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type

*sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *util::end(rng)* - *util::begin(rng)* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *rng*. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The *replace\_if* algorithm returns a *hpx::future<typename hpx::traits::range\_iterator<Rng>::type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy*. It returns *last*.

```
template<typename InIter, typename Sent, typename OutIter, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
replace_copy_result<InIter, OutIter> replace_copy(InIter first, Sent sent, OutIter dest, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

**Effects:** Assigns to every iterator *it* in the range [result, result + (sent - first)) either *new\_value* or \*(first + (it - result)) depending on whether the following corresponding condition holds: *INVOKE(proj, \*(first + (i - result))) == old\_value*

The assignments in the parallel *replace\_copy* algorithm execute in sequential order in the calling

thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace\_copy* algorithm returns an *in\_out\_result<InIter, OutIter>*. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename OutIter, typename T1, typename T2, typename Proj =  
    hpx::parallel::util::projection_identity>  
replace_copy_result<typename hpx::traits::range_iterator<Rng>::type, OutIter> replace_copy(Rng  
    &&rng,  
    OutIter  
    dest, T1  
    const  
    &old_value,  
    T2  
    const  
    &new_value,  
    Proj  
    &&proj  
    =  
    Proj())
```

Copies the all elements from the range *rbg* to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range *[result, result + (util::end(rng) - util::begin(rng))]* either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: *INVOKE(proj, \*(first + (i - result))) == old\_value*

The assignments in the parallel *replace\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace_copy` algorithm returns an `in_out_result<typename hpx::traits::range_iterator< Rng>::type, OutIter>`. The `copy` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<FwdIter1, FwdIter2>>::type replace_copy(ExPolicy
&&pol
icy,
FwdIter
first,
Sent
sent,
FwdIter
dest,
T1
const
&old_
T2
const
&new_
Proj
&&pro
=
Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range `[result, result + (sent - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of

type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace\_copy* algorithm returns a *hpx::future<in\_out\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *in\_out\_result<FwdIter1, FwdIter2>* otherwise. The *copy* algorithm returns the pair of the forward iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **Rng**, typename **FwdIter**, typename **T1**, typename **T2**,  
typename **Proj** = *hpx::parallel::util::projection\_identity*>

---

`parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<typename hpx::traits::range_iterator<Rng>::type, FwdIter, T1, T2, Proj>`

Copies the all elements from the range `rbg` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (util::end(rng) - util::begin(rng))]` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `replace_copy` algorithm returns a `hpx::future<in_out_result< typename hpx::traits::range_iterator<Rng>::type, FwdIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result< typename hpx::traits::range_iterator<Rng>::type, FwdIter>>` The `copy` algorithm returns the pair of the input iterator `last` and the forward iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Sent, typename OutIter, typename Pred, typename T,
typename Proj = hpx::parallel::util::projection_identity>
replace_copy_if_result<InIter, OutIter> replace_copy_if(InIter first, Sent sent, OutIter dest, Pred
&&pred, T const &new_value, Proj
&&proj = Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either `new_value` or \*(first + (it - result)) depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly `sent - first` applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for InIter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

<code>bool pred(const Type &amp;a);</code>
--

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new\_value** – Refers to the new value to use as the replacement.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace\_copy\_if* algorithm returns a *in\_out\_result*<*InIter*, *OutIter*>. The *replace\_copy\_if* algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename OutIter, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
replace_copy_if_result<typename hpx::traits::range_iterator<Rng>::type, OutIter> replace_copy_if(Rng &&rng, OutIter dest, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range *rng* to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range [result, result + (util::end(rng) - util::begin(rng))) either *new\_value* or \*(first + (it - result)) depending on whether the following corresponding condition holds: *(INVOKE(f, INVOKE(proj, \*(first + (i - result)))) != false*

The assignments in the parallel *replace\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* applications of the predicate.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The `replace_copy_if` algorithm returns an `in_out_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>`. The `replace_copy_if` algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>  
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_if_result<FwdIter1, FwdIter2>>::type replace_copy_if(
```

Copies the all elements from the range  $[first, sent)$  to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range  $[result, result + (sent - first))$  either *new\_value* or  $*(first + (it - result))$  depending on whether the following corresponding condition holds: `(INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it

executes the assignments.

- **FwdIter1** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for InIter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *replace\_copy\_if* algorithm returns an *hpx::future<FwdIter1, FwdIter2>*. The *replace\_copy\_if* algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter, typename Pred, typename T,  
typename Proj = hpx::parallel::util::projection_identity>  
parallel::util::detail::algorithm_result<ExPolicy>, replace_copy_if_result<typename hpx::traits::range_iterator<Rng>::type, L>
```

Copies the all elements from the range `rng` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (util::end(rng) - util::begin(rng))]` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace_copy_if` algorithm returns an `hpx::future<in_out_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>>`. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/reverse.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename Iter, typename Sent>
Iter reverse(Iter first, Sent last)
```

Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter\_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *reverse* algorithm returns a *Iter*. It returns *last*.

```
template<typename Rng>
hpx::traits::range_iterator<Rng>::type reverse(Rng &&rng)
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter\_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

**Template Parameters Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

**Parameters rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The *reverse* algorithm returns a *hpx::traits::range\_iterator<Rng>::type*. It returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent>
```

`parallel::util::detail::algorithm_result<ExPolicy, Iter>::type reverse(ExPolicy &&policy, Iter first, Sent last)`

Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter\_swap to every pair of iterators  $\text{first}+i$ ,  $(\text{last}-i) - 1$  for each non-negative  $i < (\text{last}-\text{first})/2$ .

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *reverse* algorithm returns a `hpx::future<Iter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *Iter* otherwise. It returns *last*.

template<typename ExPolicy, typename Rng>

`parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type reverse(ExPolicy &&policy, Rng &&rng, Sent first, Sent last)`

Uses *rng* as the source range, as if using `util::begin(rng)` as *first* and `ranges::end(rng)` as *last*. Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter\_swap to every pair of iterators  $\text{first}+i$ ,  $(\text{last}-i) - 1$  for each non-negative  $i < (\text{last}-\text{first})/2$ .

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The *reverse* algorithm returns a *hpx::future<typename hpx::traits::range\_iterator<Rng>::type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *hpx::future< typename hpx::traits::range\_iterator<Rng>::type>* otherwise. It returns *last*.

```
template<typename Iter, typename Sent, typename OutIter>
reverse_copy_result<Iter, OutIter> reverse_copy(Iter first, Sent last, OutIter result)
```

Copies the elements from the range [first, last) to another range beginning at result in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(\text{result} + (\text{last} - \text{first}) - 1 - i) = *(\text{first} + i)$  once for each non-negative  $i < (\text{last} - \text{first})$ . If the source and destination ranges (that is, [first, last) and [result, result+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns** The *reverse\_copy* algorithm returns a *reverse\_copy\_result<Iter, OutIter>*. The *reverse\_copy* algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename OutIter>
ranges::reverse_copy_result<typename hpx::traits::range_iterator<Rng>::type, OutIter> reverse_copy(Rng &&rng,
&&OutIter re-sult)
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Copies the elements from the range [first, last) to another range beginning at *result* in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(\text{result} + (\text{last} - \text{first})) = *(\text{first} + (\text{last} - \text{first}))$ .

$- \text{first}) - 1 - i = *(\text{first} + i)$  once for each non-negative  $i < (\text{last} - \text{first})$  If the source and destination ranges (that is,  $[\text{first}, \text{last}]$  and  $[\text{result}, \text{result} + (\text{last} - \text{first})]$  respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **OutputIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns** The *reverse\_copy* algorithm returns a `ranges::reverse_copy_result< typename hpx::traits::range_iterator<Rng>::type, OutIter>>::type`. The *reverse\_copy* algorithm returns an object equal to  $\{\text{last}, \text{result} + N\}$  where  $N = \text{last} - \text{first}$

```
template<typename ExPolicy, typename Iter, typename Sent, typename OutIter>
parallel::util::detail::algorithm_result<ExPolicy, reverse_copy_result<Iter, OutIter>>::type reverse_copy(ExPolicy &&policy,
                                                Iter first,
                                                Sent last,
                                                OutIter result)
```

Copies the elements from the range  $[\text{first}, \text{last}]$  to another range beginning at  $\text{result}$  in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(\text{result} + (\text{last} - \text{first}) - 1 - i) = *(\text{first} + i)$  once for each non-negative  $i < (\text{last} - \text{first})$  If the source and destination ranges (that is,  $[\text{first}, \text{last}]$  and  $[\text{result}, \text{result} + (\text{last} - \text{first})]$  respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns** The *reverse\_copy* algorithm returns a `hpx::future<reverse_copy_result<Iter, OutIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *reverse\_copy\_result<Iter, OutIter>* otherwise. The *reverse\_copy* algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename OutIter>
util::detail::algorithm_result<ExPolicy, ranges::reverse_copy_result<typename hpx::traits::range_iterator<Rng>::type, OutI
```

Uses *rng* as the source range, as if using `util::begin(rng)` as *first* and `ranges::end(rng)` as *last*. Copies the elements from the range `[first, last)` to another range beginning at *result* in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(\text{result} + (\text{last} - \text{first}) - 1 - i) = *(first + i)$  once for each non-negative  $i < (\text{last} - \text{first})$ . If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **OutputIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns** The *reverse\_copy* algorithm returns a *hpx::future<ranges::reverse\_copy\_result< typename hpx::traits::range\_iterator<Rng>::type, OutIter>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::reverse\_copy\_result< typename hpx::traits::range\_iterator<Rng>::type, OutIter>* otherwise. The *reverse\_copy* algorithm returns an object equal to {last, result + N} where N = last - first

## [hpx/parallel/container\\_algorithms/rotate.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent>
subrange_t<FwdIter, Sent> rotate(FwdIter first, FwdIter middle, Sent last)
```

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element *middle* becomes the first element of the new range and *middle - 1* becomes the last element.

The assignments in the parallel *rotate* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *rotate* algorithm returns a *subrange\_t<FwdIter, Sent>*. The *rotate* algorithm returns the iterator equal to pair(first + (last - middle), last).

```
template<typename ExPolicy, typename FwdIter, typename Sent>
```

---

```
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type rotate(ExPolicy
    &&policy,
    FwdIter
    first,
    FwdIter
    middle,
    Sent last)
```

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [*first*, *last*] in such a way that the element *middle* becomes the first element of the new range and *middle* - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *rotate* algorithm returns a *hpx::future<subrange\_t<FwdIter, Sent>>* if the execution policy is of type *parallel\_task\_policy* and returns a *subrange\_t<FwdIter, Sent>* otherwise. The *rotate* algorithm returns the iterator equal to pair(*first* + (*last* - *middle*), *last*).

```
template<typename Rng>
subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>> rotate(Rng
    &&rng,
    hpx::traits::range_iterator_t<Rng> middle)
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [*first*, *last*] in such a way that the element *middle* becomes the first element of the new range and *middle* - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

**Template Parameters *Rng*** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

**Parameters**

- ***rng*** – Refers to the sequence of elements the algorithm will be applied to.
- ***middle*** – Refers to the element that should appear at the beginning of the rotated range.

**Returns** The *rotate* algorithm returns a *subrange\_t<hpx::traits::range\_iterator\_t<Rng>, hpx::traits::range\_iterator\_t<Rng>>*. The *rotate* algorithm returns the iterator equal to pair(*first* + (*last* - *middle*), *last*).

```
template<typename ExPolicy, typename Rng>
util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>>
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [*first*, *last*] in such a way that the element *middle* becomes the first element of the new range and *middle* - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

**Template Parameters**

- ***ExPolicy*** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **policy** – The execution policy to use for the scheduling of the iterations.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.

**Returns** The *rotate* algorithm returns a *hpx::future* <sub-range\_t<*hpx::traits::range\_iterator\_t<Rng>*, *hpx::traits::range\_iterator\_t<Rng>*>> if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *subrange\_t<hpx::traits::range\_iterator\_t<Rng>*, *hpx::traits::range\_iterator\_t<Rng>*. otherwise. The *rotate* algorithm returns the iterator equal to pair(first + (last - middle), last).

```
template<typename FwdIter, typename Sent, typename OutIter>
rotate_copy_result<FwdIter, OutIter> rotate_copy(FwdIter first, FwdIter middle, Sent last, OutIter dest_first)
```

Copies the elements from the range [first, last), to another range beginning at *dest\_first* in such a way, that the element *middle* becomes the first element of the new range and *middle* - 1 becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *rotate\_copy* algorithm returns a *rotate\_copy\_result<FwdIter, OutIter>*. The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, rotate_copy_result<FwdIter1, FwdIter2>>::type rotate_copy(ExPolicy
&&policy,
FwdIter1
first,
FwdIter1
mid-
dle,
Sent
last,
FwdIter2
dest_first)
```

Copies the elements from the range [first, last), to another range beginning at *dest\_first* in such a way, that the element *middle* becomes the first element of the new range and *middle - 1* becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The *rotate\_copy* algorithm returns areturns `hpx::future<rotate_copy_result<FwdIter1, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `rotate_copy_result<FwdIter1, FwdIter2>` otherwise. The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

```
template<typename Rng, typename OutIter>
rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter> rotate_copy(Rng &&rng,
                                                               hpx::traits::range_iterator_t<Rng>
                                                               middle, OutIter
                                                               dest_first)
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Copies the elements from the range [first, last), to another range beginning at *dest\_first* in such a way, that the element *middle* becomes the first element of the new range and *middle - 1* becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **dest\_first** – Refers to the begin of the destination range.

**Returns** The *rotate* algorithm returns a *rotate\_copy\_result*<*hpx::traits::range\_iterator\_t<Rng>*, *OutIter*>. The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

```
template<typename ExPolicy, typename Rng, typename OutIter>
parallel::util::detail::algorithm_result<ExPolicy, rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>>::type ro
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Copies the elements from the range [*first*, *last*), to another range beginning at *dest\_first* in such a way, that the element *new\_first* becomes the first element of the new range and *new\_first* - 1 becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **dest\_first** – Refers to the begin of the destination range.

**Returns** The *rotate\_copy* algorithm returns a *hpx::future<rotate\_copy\_result<hpx::traits::range\_iterator\_t<Rng>, OutIter>>* if the execution policy is of type *parallel\_task\_policy* and returns *rotate\_copy\_result< hpx::traits::range\_iterator\_t<Rng>,*

`OutIter` otherwise. The `rotate_copy` algorithm returns the output iterator to the element past the last element copied.

## hpx/parallel/container\_algorithms/search.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent, typename FwdIter2, typename Sent2, typename Pred =  
    hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 =  
    parallel::util::projection_identity>  
FwdIter search(FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1  
    &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(s_{\text{first}}, s_{\text{last}})$  and  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter`.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter2`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate *is* invoked.

**Returns** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence  $[s\_first, s\_last)$  in range  $[first, last]$ . If the length of the subsequence  $[s\_first, s\_last)$  is greater than the length of the range  $[first, last)$ , `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search(ExPolicy &&policy, FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range  $[first, last)$  for any elements in the range  $[s\_first, s\_last)$ . Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Sent** – The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>
- **Proj1** – The type of an optional projection function. This defaults to *util::projection\_identity* and is applied to the elements of type dereferenced *FwdIter*.
- **Proj2** – The type of an optional projection function. This defaults to *util::projection\_identity* and is applied to the elements of type dereferenced *FwdIter2*.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *FwdIter1* as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *FwdIter2* as a projection operation before the actual predicate *is* invoked.

**Returns** The *search* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s\_first, s\_last) in range [first, last]. If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

```
template<typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng1>::type search(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(),
                                              Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling

thread.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of *Rng1*.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of *Rng2*.

### Parameters

- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of *rng1* as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of *rng2* as a projection operation before the actual predicate *is* invoked.

**Returns** The *search* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence  $[s\_first, s\_last]$  in range  $[\text{first}, \text{last}]$ . If the length of the subsequence  $[s\_first, s\_last]$  is greater than the length of the range  $[\text{first}, \text{last}]$ , *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred =
    hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =
    hpx::parallel::util::projection_identity

```

```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most ( $S \cdot N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of *Rng1*.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of *Rng2*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated

as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate *is* invoked.

**Returns** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence  $[s_{\text{first}}, s_{\text{last}}]$  in range  $[\text{first}, \text{last}]$ . If the length of the subsequence  $[s_{\text{first}}, s_{\text{last}}]$  is greater than the length of the range  $[\text{first}, \text{last}]$ , `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```
template<typename FwdIter, typename FwdIter2, typename Sent2, typename Pred =  
hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 =  
parallel::util::projection_identity>  
FwdIter search_n(ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, Sent s_last,  
Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range  $[\text{first}, \text{last}]$  for any elements in the range  $[s_{\text{first}}, s_{\text{last}}]$ . Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(S^*N)$  comparisons where  $S = \text{distance}(s_{\text{first}}, s_{\text{last}})$  and  $N = \text{count}$ .

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate *is* invoked.

**Returns** The `search_n` algorithm returns `FwdIter`. The `search_n` algorithm returns an iterator to the beginning of the last subsequence  $[s\_first, s\_last)$  in range  $[first, first+count]$ . If the length of the subsequence  $[s\_first, s\_last)$  is greater than the length of the range  $[first, first+count]$ , `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search_n(ExPolicy &&policy, FwdIter first,
                                                               std::size_t count, FwdIter2 s_first,
                                                               Sent2 s_last, Pred &&op = Pred(),
                                                               Proj1 &&proj1 = Proj1(), Proj2
                                                               &&proj2 = Proj2())
```

Searches the range  $[first, last)$  for any elements in the range  $[s\_first, s\_last)$ . Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{count}$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of

*CopyConstructible*. This defaults to std::equal\_to<>

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *FwdIter1* as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced *FwdIter2* as a projection operation before the actual predicate *is* invoked.

**Returns** The *search\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search\_n* algorithm returns an iterator to the beginning of the last subsequence [s\_first, s\_last) in range [first, first+count). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, first+count), *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

```
template<typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng1>::type search_n(Rng1 &&rng1, std::size_t count, Rng2 &&rng2, Pred
&&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2
&&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most ( $S \cdot N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

#### Template Parameters

- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>
- **Proj1** – The type of an optional projection function. This defaults to *util::projection\_identity* and is applied to the elements of *Rng1*.
- **Proj2** – The type of an optional projection function. This defaults to *util::projection\_identity* and is applied to the elements of *Rng2*.

**Parameters**

- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **count** – The number of elements to apply the algorithm on.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of *rng1* as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of *rng2* as a projection operation before the actual predicate *is* invoked.

**Returns** The *search* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s\_first, s\_last) in range [first, last]. If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred =  
hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 =  
hpx::parallel::util::projection_identity>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type search_n(
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most ( $S^*N$ ) comparisons where  $S = \text{distance}(\text{s\_first}, \text{s\_last})$  and  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of *Rng1*.
- **Proj2** – The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of *Rng2*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **count** – The number of elements to apply the algorithm on.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of *rng1* as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of *rng2* as a projection operation before the actual predicate *is* invoked.

**Returns** The *search* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s\_first, s\_last) in range [first, last]. If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

## hpx/parallel/container\_algorithms/set\_difference.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
         typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename
         Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, ranges::set_difference_result<Iter1, Iter3>>::type set_difference(ExPolicy
    &&policy,
    Iter1
    first1,
    Sent1
    last1,
    Iter2
    first2,
    Sent2
    last2,
    Iter3
    dest,
    Pred
    &&op
    =
    Pred(),
    Proj1
    &&proj1
    =
    Proj1(),
    Proj2
    &&proj2
    =
    Proj2())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::max(m-n, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread

spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op*

is invoked.

**Returns** The *set\_difference* algorithm returns a *hpx::future<ranges::set\_difference\_result<Iter1, Iter3>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::set\_difference\_result<Iter1, Iter3>* otherwise. The *set\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity> util::detail::algorithm_result<ExPolicy, ranges::set_difference_result<typename traits::range_iterator<Rng1>::type, Iter3>>
```

Constructs a sorted range beginning at *dest* consisting of all elements present in the range [*first1*, *last1*) and not present in the range [*first2*, *last2*). This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

Equivalent elements are treated individually, that is, if some element is found *m* times in [*first1*, *last1*) and *n* times in [*first2*, *last2*), it will be copied to *dest* exactly *std::max(m-n, 0)* times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *set\_difference* algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. where *Iter1* is `range_iterator_t<Rng1>` and *Iter2* is `range_iterator_t<Rng2>` The *set\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/set\_intersection.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename
Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, ranges::set_intersection_result<Iter1, Iter2, Iter3>>::type set_intersection(ExPolicy policy, Iter1 first1, Iter1 last1, Iter2 first2, Iter2 last2, Pred pred, Proj1 proj1, Proj2 proj2)
```

Constructs a sorted range beginning at `dest` consisting of all elements present in both sorted ranges `[first1, last1]` and `[first2, last2]`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found  $m$  times in `[first1, last1]` and  $n$  times in `[first2, last2]`, the first `std::min(m, n)` elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object `execute` in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2^*(N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *set\_intersection* algorithm returns a `hpx::future<ranges::set_intersection_result<Iter1, Iter2, Iter3>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>` otherwise. The *set\_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```

`util::detail::algorithm_result<ExPolicy, ranges::set_intersection_result<typename traits::range_iterator<Rng1>::type, typename traits::range_iterator<Rng2>::type, typename traits::range_iterator<Iter3>::type>`

Constructs a sorted range beginning at `dest` consisting of all elements present in both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found  $m$  times in `[first1, last1)` and  $n$  times in `[first2, last2)`, the first `std::min(m, n)` elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *set\_intersection* algorithm returns a *hpx::future<ranges::set\_intersection\_result<Iter1, Iter2, Iter3>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::set\_intersection\_result<Iter1, Iter2, Iter3>* otherwise. where *Iter1* is *range\_iterator\_t<Rng1>* and *Iter2* is *range\_iterator\_t<Rng2>* The *set\_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/set\_symmetric\_difference.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
        typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename
        Proj2 = util::projection_identity

```

`util::detail::algorithm_result<ExPolicy, ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>::type` **set\_symmetric\_difference**

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges [*first1*, *last1*) and [*first2*, *last2*), but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in [*first1*, *last1*) and *n* times in [*first2*, *last2*), it will be copied to *dest* exactly `std::abs(m-n)` times. If *m*>*n*, then the last *m-n* of those elements are copied from [*first1*,*last1*), otherwise the last *n-m* elements are copied from [*first2*,*last2*). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *set\_symmetric\_difference* algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity

```

```
util::detail::algorithm_result<ExPolicy, ranges::set_symmetric_difference_result<typename traits::range_iterator<Rng1>::type
```

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges [*first1*, *last1*] and [*first2*, *last2*], but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in [*first1*, *last1*] and *n* times in [*first2*, *last2*], it will be copied to *dest* exactly `std::abs(m-n)` times. If *m*>*n*, then the last *m-n* of those elements are copied from [*first1*,*last1*), otherwise the last *n-m* elements are copied from [*first2*,*last2*). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object `execute` in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2*(N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const &**, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *set\_symmetric\_difference* algorithm returns a *hpx::future<ranges::set\_symmetric\_difference\_result<Iter1, Iter2, Iter3>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::set\_symmetric\_difference\_result<Iter1, Iter2, Iter3>* otherwise. where *Iter1* is *range\_iterator\_t<Rng1>* and *Iter2* is *range\_iterator\_t<Rng2>* The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx/parallel/container\_algorithms/set\_union.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename
Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, ranges::set_union_result<Iter1, Iter2, Iter3>>::type set_union(ExPolicy
&&policy,
Iter1
first1,
Sent1
last1,
Iter2
first2,
Sent2

=
Pred(),
Proj1
&&proj1
=
Proj1(),
Proj2
&&proj2
=
Proj2())
```

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), then all *m* elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2^*(N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

**Returns** The *set\_union* algorithm returns a `hpx::future<ranges::set_union_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_union_result<Iter1, Iter2, Iter3>` otherwise. where *Iter1* is `range_iterator_t<Rng1>` and *Iter2* is `range_iterator_t<Rng2>` The *set\_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/shift\_left.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent, typename Size>
FwdIter shift_left(FwdIter first, Sent last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position  $\text{first} + n + i$  to position  $\text{first} + i$ .

The assignment operations in the parallel *shift\_left* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_left* algorithm returns *FwdIter*. The *shift\_left* algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_left(ExPolicy &&policy, FwdIter
first, Sent last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_left* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *shift\_left* algorithm returns an iterator to the end of the resulting range.

```
template<typename Rng, typename Size>
hpx::traits::range_iterator_t<Rng> shift_left(Rng &&rng, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift\_left* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

**Note:** Complexity: At most (last - first) - n assignments.

**Note:** The type of dereferenced *hpx::traits::range\_iterator\_t<Rng>* must meet the requirements of *MoveAssignable*.

#### Template Parameters

- **Rng** – The type of the range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

#### Parameters

- **rng** – Refers to the range in which the elements will be shifted.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_left* algorithm returns *hpx::traits::range\_iterator\_t<Rng>*. The *shift\_left* algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename Rng, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>>::type shift_left(ExPolicy &&pol-  
ic平,  
Rng &&rng,  
Size n)
```

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced `hpx::traits::range_iterator_t<Rng>` must meet the requirements of `MoveAssignable`.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the range in which the elements will be shifted.
- **n** – Refers to the number of positions to shift.

**Returns** The `shift_left` algorithm returns a `hpx::future<hpx::traits::range_iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `hpx::traits::range_iterator_t<Rng>` otherwise. The `shift_left` algorithm returns an iterator to the end of the resulting range.

## hpx/parallel/container\_algorithms/shift\_right.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

#### Functions

```
template<typename FwdIter, typename Sent, typename Size>
FwdIter shift_right(FwdIter first, Sent last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- $n + i$ .

The assignment operations in the parallel `shift_right` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced `FwdIter` must meet the requirements of `MoveAssignable`.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_right* algorithm returns *FwdIter*. The *shift\_right* algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_right(ExPolicy &&policy, FwdIter
first, Sent last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_right* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *shift\_right* algorithm returns an iterator to the end of the resulting range.

```
template<typename Rng, typename Size>
hpx::traits::range_iterator_t<Rng> shift_right(Rng &&rng, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift\_right* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

**Note:** The type of dereferenced *hpx::traits::range\_iterator\_t<Rng>* must meet the requirements of *MoveAssignable*.

---

#### Template Parameters

- **Rng** – The type of the range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

#### Parameters

- **rng** – Refers to the range in which the elements will be shifted.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_right* algorithm returns *hpx::traits::range\_iterator\_t<Rng>*. The *shift\_right* algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename Rng, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>>::type shift_right(ExPolicy
&&policy,
Rng
&&rng,
Size
n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

**Note:** The type of dereferenced *hpx::traits::range\_iterator\_t<Rng>* must meet the requirements of *MoveAssignable*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the range in which the elements will be shifted.
- **n** – Refers to the number of positions to shift.

**Returns** The *shift\_right* algorithm returns a *hpx::future<hpx::traits::range\_iterator\_t<Rng>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *hpx::traits::range\_iterator\_t<Rng>* otherwise. The *shift\_right* algorithm returns an iterator to the end of the resulting range.

**hpx/parallel/container\_algorithms/sort.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

**Functions**

```
template<typename RandomIt, typename Sent, typename Comp, typename Proj>
RandomIt sort(RandomIt first, Sent last, Comp &&comp, Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and *Invoke(comp, Invoke(proj, \*(i + n)), Invoke(proj, \*i)) == false*.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel *sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: O(Nlog(N)), where N = *detail::distance(first, last)* comparisons.

**Template Parameters**

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *RandomIt*.
- **Comp** – The type of the function/function object to use (deduced).

- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *sort* algorithm returns *RandomIt*. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```
template<typename ExPolicy, typename RandomIt, typename Sent, typename Comp, typename Proj>
parallel::util::detail::algorithm_result<ExPolicy, RandomIt>::type sort(ExPolicy &&policy, RandomIt
first, Sent last, Comp &&comp,
Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and `(INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.`

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{detail}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *RandomIt*.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *sort* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandomIt* otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```
template<typename Rng, typename Comp, typename Proj>
hpx::traits::range_iterator<Rng>::type sort(Rng &&rng, Compare &&comp, Proj &&proj)
```

Sorts the elements in the range *rng* in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and *(INVOKE(comp, INVOKE(proj, \*(i + n)), INVOKE(proj, \*i)) == false)*.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel *sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{begin}(\text{rng}), \text{end}(\text{rng}))$  comparisons.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *sort* algorithm returns *typename hpx::traits::range\_iterator<Rng>::type*. It returns *last*.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj>
```

```
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator_t<Rng>>::type sort(ExPolicy
    &&policy,
    Rng
    &&rng,
    Comp
    &&comp,
    Proj&&)
```

Sorts the elements in the range *rng* in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and INVOKE(*comp*, INVOKE(*proj*, \*(*i* + *n*)), INVOKE(*proj*, \**i*)) == false.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(Nlog(N)), where N = std::distance(begin(rng), end(rng)) comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *sort* algorithm returns a *hpx::future<typename hpx::traits::range\_iterator\_t<*Rng*>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *typename hpx::traits::range\_iterator<*Rng*>::type* otherwise. It returns *last*.

## hpx/parallel/container\_algorithms/stable\_sort.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename RandomIt, typename Sent, typename Comp, typename Proj>
RandomIt stable_sort(RandomIt first, Sent last, Comp &&comp, Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and  $\text{(INVOKE}(\text{comp}, \text{VOKE}(\text{proj}, *(\text{i} + \text{n})), \text{VOKE}(\text{proj}, *\text{i})) == \text{false}$ .

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel *stable\_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity:  $O(N\log(N))$ , where  $N = \text{std::distance(first, last)}$  comparisons.

#### Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *stable\_sort* algorithm returns *RandomIt*. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```
template<typename ExPolicy, typename RandomIt, typename Sent, typename Comp, typename Proj>
```

```
parallel::util::detail::algorithm_result<ExPolicy, RandomIt>::type stable_sort(ExPolicy &&policy,  
RandomIt first, Sent  
last, Comp &&comp,  
Proj &&proj)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, \*(i + n)), INVOKE(proj, \*i)) == false.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *stable\_sort* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandomIt* otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

template<typename Rng, typename Comp, typename Proj>

---

`hpx::traits::range_iterator<Rng>::type stable_sort(Rng &&rng, Compare &&comp, Proj &&proj)`

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel *stable\_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the `INVOKE` operation applied to an object of type *Comp*, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *stable\_sort* algorithm returns *typename hpx::traits::range\_iterator<Rng>::type*.

It returns *last*.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator_t<Rng>>::type stable_sort(ExPolicy
&&policy,
Rng
&&rng,
Comp
&&comp,
Proj&&)
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object *comp* (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std}::\text{distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to *bool*, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

**Returns** The *stable\_sort* algorithm returns a *hpx::future<typename hpx::traits::range\_iterator\_t<Rng>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *typename hpx::traits::range\_iterator<Rng>::type* otherwise. It returns *last*.

## [hpx/parallel/container\\_algorithms/stable\\_sort.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **ranges**

## Functions

```
template<typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2, typename Pred, typename Proj1, typename Proj2starts_with(FwdIter1 first1, Sent1 last1, FwdIter2 first2, Sent2 last2, Pred &&pred, Proj1&&proj1, Proj2 &&proj2)
```

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2)

The assignments in the parallel *starts\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

### Template Parameters

- **Iter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the end source iterators used(deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a input iterator.
- **Sent2** – The type of the end destination iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj1** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

### Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate is invoked.

**Returns** The *starts\_with* algorithm returns *bool*. The *starts\_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2, typename Pred, typename Proj1, typename Proj2

```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type starts_with(ExPolicy &&policy,  
                           FwdIter1 first1, Sent1  
                           last1, FwdIter2 first2,  
                           Sent2 last2, Pred  
                           &&pred, Proj1  
                           &&proj1, Proj2  
                           &&proj2)
```

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2)

The assignments in the parallel *starts\_with* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *starts\_with* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used(deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **FwdIter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the end destination iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj1** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate *is* invoked.

**Returns** The *starts\_with* algorithm returns a *hpx::future<bool>* if the execution policy is

of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *starts\_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

```
template<typename Rng1, typename Rng2, typename Pred, typename Proj1, typename Proj2>
bool starts_with(Rng1 &&rng1, Rng2 &&rng2, Pred &&pred, Proj1 &&proj1, Proj2 &&proj2)
```

Checks whether the second range *rng2* matches the prefix of the first range *rng1*.

The assignments in the parallel *starts\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

#### Parameters

- **rng1** – Refers to the source range.
- **rng2** – Refers to the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate is invoked.

**Returns** The *starts\_with* algorithm returns *bool*. The *starts\_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred, typename Proj1,
        typename Proj2>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type starts_with(ExPolicy &&policy,
    Rng1 &&rng1, Rng2
    &&rng2, Pred
    &&pred, Proj1
    &&proj1, Proj2
    &&proj2)
```

Checks whether the second range *rng2* matches the prefix of the first range *rng1*.

The assignments in the parallel *starts\_with* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *starts\_with* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to *util::projection\_identity*
- **Proj1** – The type of an optional projection function for the destination range. This defaults to *util::projection\_identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the source range.
- **rng2** – Refers to the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate *is* invoked.

**Returns** The *starts\_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *starts\_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

## hpx/parallel/container\_algorithms/swap\_ranges.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **ranges**

## Functions

```
template<typename InIter1, typename Sent1, typename InIter2, typename Sent2>
swap_ranges_result<InIter1, InIter2> swap_ranges(InIter1 first1, Sent1 last1, InIter2 first2, Sent2 last2)
    Exchanges elements between range [first1, last1) and another range starting at first2.
```

The swap operations in the parallel *swap\_ranges* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*

---

### Template Parameters

- **InIter1** – The type of the first range of iterators to swap (deduced).
- **Sent1** – The type of the first sentinel (deduced). This sentinel type must be a sentinel for InIter1.
- **InIter2** – The type of the second range of iterators to swap (deduced).
- **Sent2** – The type of the second sentinel (deduced). This sentinel type must be a sentinel for InIter2.

### Parameters

- **first1** – Refers to the beginning of the sequence of elements for the first range.
- **last1** – Refers to sentinel value denoting the end of the sequence of elements for the first range.
- **first2** – Refers to the beginning of the sequence of elements for the second range.
- **last2** – Refers to sentinel value denoting the end of the sequence of elements for the second range.

**Returns** The *swap\_ranges* algorithm returns *swap\_ranges\_result*<*InIter1*, *InIter2*>. The *swap\_ranges* algorithm returns *in\_in\_result* with the first element as the iterator to the element past the last element exchanged in range beginning with *first1* and the second element as the iterator to the element past the last element exchanged in the range beginning with *first2*.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2>
parallel::util::detail::algorithm_result<ExPolicy, swap_ranges_result<FwdIter1, FwdIter2>>::type swap_ranges(ExPolicy
    &&policy,
    FwdIter1
    first1,
    Sent1
    last1,
    FwdIter2
    first2,
    Sent2
    last2)
```

Exchanges elements between range [first1, last1) and another range starting at first2.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in

unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first range of iterators to swap (deduced).
- **Sent1** – The type of the first sentinel (deduced). This sentinel type must be a sentinel for FwdIter1.
- **FwdIter2** – The type of the second range of iterators to swap (deduced).
- **Sent2** – The type of the second sentinel (deduced). This sentinel type must be a sentinel for FwdIter2.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements for the first range.
- **last1** – Refers to sentinel value denoting the end of the sequence of elements for the first range.
- **first2** – Refers to the beginning of the sequence of elements for the second range.
- **last2** – Refers to sentinel value denoting the end of the sequence of elements for the second range.

**Returns** The *swap\_ranges* algorithm returns a *hpx::future<swap\_ranges\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *swap\_ranges* algorithm returns *in\_in\_result* with the first element as the iterator to the element past the last element exchanged in range beginning with *first1* and the second element as the iterator to the element past the last element exchanged in the range beginning with *first2*.

```
template<typename Rng1, typename Rng2>
swap_ranges_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng2>> swap_ranges(Rng1
&&rng1,
Rng2
&&rng2)
```

Exchanges elements between range [*first1*, *last1*] and another range starting at *first2*.

The swap operations in the parallel *swap\_ranges* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **rng1** – Refers to the sequence of elements of the first range.
- **rng2** – Refers to the sequence of elements of the second range.

**Returns** The *swap\_ranges* algorithm returns *swap\_ranges\_result<hpx::traits::range\_iterator\_t<Rng1>, hpx::traits::range\_iterator\_t<Rng1>>*. The

*swap\_ranges* algorithm returns `in_in_result` with the first element as the iterator to the element past the last element exchanged in range beginning with `first1` and the second element as the iterator to the element past the last element exchanged in the range beginning with `first2`.

```
template<typename ExPolicy, typename Rng1, typename Rng2>
```

```
parallel::util::detail::algorithm_result<ExPolicy, swap_ranges_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_
```

Exchanges elements between range `[first1, last1)` and another range starting at `first2`.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between `first1` and `last1`

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements of the first range.
- **rng2** – Refers to the sequence of elements of the second range.

**Returns** The *swap\_ranges* algorithm returns a `hpx::future<swap_ranges_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng1>>>` if the execution policy is of type *parallel\_task\_policy* and returns `swap_ranges_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng1>>`. otherwise. The *swap\_ranges* algorithm returns `in_in_result` with the first element as the iterator to the element past the last element exchanged in range beginning with `first1` and the second element as the iterator to the element past the last element exchanged in the range beginning with `first2`.

## hpx/parallel/container\_algorithms/transform.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Rng, typename OutIter, typename F, typename Proj =  
util::projection_identity>  
util::detail::algorithm_result<ExPolicy, ranges::unary_transform_result<typename hpx::traits::range_iterator<Rng>::type, C>
```

Applies the given function  $f$  to the given range  $rng$  and stores the result in another range, beginning at  $dest$ .

The invocations of  $f$  in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The invocations of  $f$  in the parallel *transform* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\text{size}(rng)$  applications of  $f$

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of  $f$ .
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires  $F$  to meet the requirements of *CopyConstructible*.

- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `range_iterator<Rng>::type` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `OutIter` can be dereferenced and assigned a value of type `Ret`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

**Returns** The `transform` algorithm returns a `hpx::future<ranges::unary_transform_result<range_iterator<Rng>::type, OutIter> >` if the execution policy is of type `parallel_task_policy` and returns `ranges::unary_transform_result<range_iterator<Rng>::type, OutIter>` otherwise.

The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename F, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, ranges::unary_transform_result<FwdIter1, FwdIter2>>::type transform(
```

Applies the given function `f` to the given range `rng` and stores the result in another range, beginning at `dest`.

The invocations of `f` in the parallel `transform` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The invocations of `f` in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\text{size}(\text{rng})$  applications of  $f$

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of  $f$ .
- **FwdIter1** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.
- **FwdIter2** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires  $F$  to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *Ret* must be such that an object of type *FwdIter2* can be dereferenced and assigned a value of type *Ret*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate  $f$  is invoked.

**Returns** The *transform* algorithm returns a `hpx::future<ranges::unary_transform_result<FwdIter1, FwdIter2>>` if the execution policy is of type `parallel_task_policy` and returns `ranges::unary_transform_result<FwdIter1, FwdIter2>` otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **Sent1**, typename **FwdIter2**, typename **Sent2**, typename **FwdIter3**, typename **F**, typename **Proj1** = `hpx::parallel::util::projection_identity`, typename **Proj2** = `hpx::parallel::util::projection_identity`>

`parallel::util::detail::algorithm_result<ExPolicy, ranges::binary_transform_result<FwdIter1, FwdIter2, FwdIter3>>::type t`

Applies the given function  $f$  to pairs of elements from two ranges: one defined by  $rng$  and the other beginning at  $first2$ , and stores the result in another range, beginning at  $dest$ .

The invocations of  $f$  in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The invocations of  $f$  in the parallel *transform* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\text{size}(rng)$  applications of  $f$

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of  $f$ .
- **FwdIter1** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `FwdIter1`.
- **FwdIter2** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `FwdIter2`.
- **FwdIter3** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires  $F$  to meet the requirements of *CopyConstructible*.

- **Proj1** – The type of an optional projection function to be used for elements of the first sequence. This defaults to *util::projection\_identity*
- **Proj2** – The type of an optional projection function to be used for elements of the second sequence. This defaults to *util::projection\_identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively. The type *Ret* must be such that an object of type *FwdIter3* can be dereferenced and assigned a value of type *Ret*.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *f* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *f* is invoked.

**Returns** The *transform* algorithm returns a *hpx::future<ranges::binary\_transform\_result<FwdIter1, FwdIter2, FwdIter3>>* if the execution policy is of type *parallel\_task\_policy* and returns *ranges::binary\_transform\_result<FwdIter1, FwdIter2, FwdIter3>* otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

## [hpx/parallel/container\\_algorithms/transform\\_exclusive\\_scan.hpp](#)

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename InIter, typename Sent, typename OutIter, typename T, typename BinOp,
typename UnOp>
transform_exclusive_scan_result<InIter, OutIter> transform_exclusive_scan(InIter first, Sent last,
OutIter dest, T init,
BinOp &&binary_op,
UnOp &&unary_op)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*first + (i - result) - 1))).

The reduce operations in the parallel *transform\_exclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first, last) or [result, result + (last - first)).

The behavior of *transform\_exclusive\_scan* may be non-deterministic for a non-associative predicate.

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,  $a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
- $op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_1, \dots, a_K), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_{M+1}, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for **InIter**.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

R **fun**(**const** Type &a);

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be derefer-

enced and then implicitly converted to Type. The type  $R$  must be such that an object of this type can be implicitly converted to  $T$ .

- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `transform_exclusive_scan` algorithm returns `transform_exclusive_scan_result<InIter, OutIter>`. The `transform_exclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename T,  
typename BinOp, typename UnOp>  
parallel::util::detail::algorithm_result<ExPolicy, transform_exclusive_result<FwdIter1, FwdIter2>>::type transform_exclu
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), \dots, conv(*(first + (i - result) - 1)))`.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of `transform_exclusive_scan` may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates `op` and `conv`.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1
  - op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, ..., aN)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The *transform\_exclusive\_scan* algorithm returns a *hpx::future<transform\_exclusive\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_exclusive\_result<FwdIter1, FwdIter2>* otherwise. The *transform\_exclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

template<typename **Rng**, typename **O**, typename **T**, typename **BinOp**, typename **UnOp**>

```
transform_exclusive_scan_result<traits>::range_iterator_t<Rng>, O) transform_exclusive_scan(Rng
&&rng,
O
dest,
T
init,
BinOp
&&bi-
nary_op,
UnOp
&&unary_op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result) - 1))).

The reduce operations in the parallel *transform\_exclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of *transform\_exclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a1, ..., aN) is defined as:

- a1 when N is 1
  - op(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, aM, ..., aN)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **O** – The type of the iterator representing the destination range (deduced).
- **Conv** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

R <b>fun</b> ( <b>const</b> Type &a);
---------------------------------------

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `transform_exclusive_scan` algorithm returns a `transform_exclusive_scan_result< traits::range_iterator_t<Rng>, O>`. The `transform_exclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename O, typename T, typename BinOp, typename UnOp>
parallel::util::detail::algorithm_result<ExPolicy, transform_exclusive_scan_result<traits::range_iterator_t<Rng>, O>>::type
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), \dots, conv(*(first + (i - result) - 1)))`.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of `transform_exclusive_scan` may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates `op` and `conv`.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, \dots, aN)` is defined as:

- $a1$  when  $N$  is 1

- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator. This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `transform_exclusive_scan` algorithm returns a `hpx::future<transform_exclusive_scan_result< traits::range_iterator_t<Rng>, O>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `transform_exclusive_scan_result< traits::range_iterator_t<Rng>, O>` otherwise. The `transform_exclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

## `hpx/parallel/container_algorithms/transform_inclusive_scan.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent, typename OutIter, typename BinOp, typename UnOp>
transform_inclusive_scan_result<InIter, OutIter> transform_inclusive_scan(InIter first, Sent last,
                                                               OutIter dest, BinOp
                                                               &&binary_op, UnOp
                                                               &&unary_op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(op, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as:

- *a*<sub>1</sub> when N is 1
- *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>K</sub>), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>M</sub>, ..., *a*<sub>N</sub>) where  $1 < K+1 = M \leq N$ .

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **Conv** – The type of the unary function object used for the conversion operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

**Returns** The *transform\_inclusive\_scan* algorithm returns *transform\_inclusive\_scan\_result<InIter, OutIter>*. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename BinOp, typename UnOp>  
parallel::util::detail::algorithm_result<ExPolicy, transform_inclusive_result<FwdIter1, FwdIter2>>::type transform_inclusive_scan(FwdIter1 first, FwdIter1 last, Sent result, ExPolicy exPolicy, FwdIter2 dest, BinOp binOp, UnOp unOp);
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(op, conv(\*first), ..., conv(\*(first + (i - result))))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first, last) or [result, result + (last - first)).

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *op* and *conv*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*1, ..., *a*K), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*M, ..., *a*N)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **Conv** – The type of the unary function object used for the conversion operation.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

**Returns** The *transform\_inclusive\_scan* algorithm returns a *hpx::future<transform\_inclusive\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_inclusive\_result<FwdIter1, FwdIter2>* otherwise. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename O, typename BinOp, typename UnOp>
transform_inclusive_scan_result<traits::range_iterator_t<Rng>, O> transform_inclusive_scan(Rng
&&rng,
O
dest,
BinOp
&&bi-
nary_op,
UnOp
&&unary_op)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM( $op, conv(*first), \dots, conv(*(\text{first} + (i - result)))$ ).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM( $op, a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
  - $op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_1, \dots, a_K), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_M, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **O** – The type of the iterator representing the destination range (deduced).
- **Op** – The type of the binary function object used for the reduction operation.
- **Conv** – The type of the unary function object used for the conversion operation.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

Ret <b>fun</b> ( <b>const</b> Type1 &a, <b>const</b> Type1 &b);
---

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by  $[first, last)$ . This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

**Returns** The `transform_inclusive_scan` algorithm returns a `transform_inclusive_scan_result< traits::range_iterator_t<Rng>, O>`. The `transform_inclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename O, typename BinOp, typename UnOp>
parallel::util::detail::algorithm_result<ExPolicy, transform_inclusive_scan_result<traits::range_iterator_t<Rng>, O>>::type
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of `transform_inclusive_scan` may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates `op` and `conv`.

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- $a1$  when  $N$  is 1
  - $op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, ..., aN))$  where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it

executes the assignments.

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator. This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

**Returns** The `transform_inclusive_scan` algorithm returns a `hpx::future<transform_inclusive_scan_result< traits::range_iterator_t<Rng>, O>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `transform_inclusive_scan_result< traits::range_iterator_t<Rng>, O>` otherwise. The `transform_inclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Sent, typename OutIter, typename BinOp, typename UnOp,  
        typename T>  
transform_inclusive_scan_result<InIter, OutIter> transform_inclusive_scan(InIter first, Sent last,  
                           OutIter dest, BinOp  
                           &&binary_op, UnOp  
                           &&unary_op, T init)
```

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of `transform_inclusive_scan` may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates `op` and `conv`.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- $a1$  when  $N$  is 1
  - $\text{op}(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a1, \dots, aK), \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, aM, \dots, aN))$  where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The `transform_inclusive_scan` algorithm returns `transform_inclusive_scan_result<InIter, OutIter>`. The `transform_inclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **Sent**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**, typename **T**>

*parallel::util::detail::algorithm\_result<ExPolicy, transform\_inclusive\_result<FwdIter1, FwdIter2>>::type* **transform\_incl**

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first, last) or [result, result + (last - first)).

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*,  $a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
  - $op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_1, \dots, a_K), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_{M+1}, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.

- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The *transform\_inclusive\_scan* algorithm returns a *hpx::future<transform\_inclusive\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_inclusive\_result<FwdIter1, FwdIter2>* otherwise. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename O, typename BinOp, typename UnOp, typename T>
transform_inclusive_scan_result<traits::range_iterator_t<Rng>, O> transform_inclusive_scan(Rng
&&rng,
O
dest,
BinOp
&&bi-
nary_op,
UnOp
&&unary_op,
T
init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges [first,last) or [result,result + (last - first)].

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

---

**Note:** *GENERALIZED\_NONCOMMUTATIVE\_SUM*(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as:

- *a*<sub>1</sub> when N is 1
  - *op*(*GENERALIZED\_NONCOMMUTATIVE\_SUM*(*op*, *a*<sub>1</sub>, ..., *a*<sub>K</sub>), *GENERALIZED\_NONCOMMUTATIVE\_SUM*(*op*, *a*<sub>M</sub>, ..., *a*<sub>N</sub>) where  $1 < K+1 = M \leq N$ ).
- 

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **O** – The type of the iterator representing the destination range (deduced).
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The *transform\_inclusive\_scan* algorithm returns a *transform\_inclusive\_scan\_result*< *traits::range\_iterator\_t*<*Rng*>, *O*>. The *transform\_inclusive\_scan* algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **Rng**, typename **O**, typename **BinOp**, typename **UnOp**, typename **T**>

---

`parallel::util::detail::algorithm_result<ExPolicy, transform_inclusive_scan_result<traits::range_iterator_t<Rng>, O>>::type`

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of GENERALIZED\_NONCOMMUTATIVE\_SUM( $binary\_op$ ,  $init$ ,  $conv(*first), \dots, conv(*(first + (i - result)))$ ).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or subranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM( $op, a_1, \dots, a_N$ ) is defined as:

- $a_1$  when  $N$  is 1
  - $op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_1, \dots, a_K), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a_M, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator. This iterator type must meet the requirements of an forward iterator.
- **Conv** – The type of the unary function object used for the conversion operation.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **conv** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The `transform_inclusive_scan` algorithm returns a `hpx::future<transform_inclusive_scan_result< traits::range_iterator_t<Rng>, O>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `transform_inclusive_scan_result< traits::range_iterator_t<Rng>, O>` otherwise. The `transform_inclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/transform\_reduce.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename Rng, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng &&rng, T
init, Reduce &&red_op, Convert
&&conv_op)
```

Returns `GENERALIZED_SUM(red_op, init, conv_op(*first), ..., conv_op(*(first + (last - first) - 1)))`.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform\_reduce* and *accumulate* is that the behavior of *transform\_reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *red\_op* and *conv\_op*.

---

**Note:** GENERALIZED\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as follows:

- *a*<sub>1</sub> when *N* is 1
  - *op*(GENERALIZED\_SUM(*op*, *b*<sub>1</sub>, ..., *b*<sub>K</sub>), GENERALIZED\_SUM(*op*, *b*<sub>M</sub>, ..., *b*<sub>N</sub>)), where:
    - *b*<sub>1</sub>, ..., *b*<sub>N</sub> may be any permutation of *a*<sub>1</sub>, ..., *a*<sub>N</sub> and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv\_op* can be implicitly converted to any of those types.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `Iter` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

**Returns** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `parallel_task_policy` and returns `T` otherwise. The `transform_reduce` algorithm returns the result of the generalized sum over the values returned from `conv_op` when applied to the elements given by the input range `[first, last)`.

```
template<typename ExPolicy, typename Rng1, typename FwdIter2, typename T>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng1 &&rng1,
                                                               FwdIter2 first2, T init)
```

Returns the result of accumulating `init` with the inner products of the pairs formed by the elements of two ranges starting at `first1` and `first2`.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate `op2`.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

**Returns** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise.

```
template<typename ExPolicy, typename Rng1, typename FwdIter2, typename T, typename Reduce,
        typename Convert>
```

---

```
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng1 &&rng1,
                                                               FwdIter2 first2, T init, Reduce
                                                               &&red_op, Convert &&conv_op)
```

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op2*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *op2*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

Ret <b>fun</b> ( <b>const</b> Type1 &a, <b>const</b> Type1 &b);
---

The signature does not need to have **const&**, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Ret` must be such that it can be implicitly converted to an object for the second argument type of `op1`.

**Returns** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise.

## hpx/parallel/container\_algorithms/uninitialized\_copy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent1, typename FwdIter, typename Sent2>
hpx::parallel::util::in_out_result<InIter, FwdIter> uninitialized_copy(InIter first1, Sent1 last1,
                                                               FwdIter first2, Sent2 last2)
```

Copies the elements in the range, defined by `[first, last)`, to an uninitialized memory area beginning at `dest`. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel `uninitialized_copy` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly `last - first` assignments.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter2`.

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements that will be copied from
- **last1** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The `uninitialized_copy` algorithm returns an `in_out_result<InIter, FwdIter>`. The `uninitialized_copy` algorithm returns an input iterator to one past the last element copied

from and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2>
parallel::util::detail::algorithm_result<ExPolicy, parallel::util::in_out_result<FwdIter1, FwdIter2>>::type uninitialized_copy
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter2.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements that will be copied from
- **last1** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The *uninitialized\_copy* algorithm returns a *hpx::future<in\_out\_result<InIter, FwdIter>>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *in\_out\_result<InIter, FwdIter>* otherwise. The *uninitialized\_copy* algorithm returns an input iterator to one past the last element copied from and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng1, typename Rng2>
hpx::parallel::util::in_out_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type>
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

#### Parameters

- **rng1** – Refers to the range from which the elements will be copied from
- **rng2** – Refers to the range to which the elements will be copied to

**Returns** The *uninitialized\_copy* algorithm returns an *in\_out\_result<typename hpx::traits::range\_traits<Rng1>::iterator\_type, typename hpx::traits::range\_traits<Rng2>::iterator\_type>*. The *uninitialized\_copy* algorithm returns an input iterator to one past the last element copied from and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng1, typename Rng2>
```

```
parallel::util::detail::algorithm_result<ExPolicy, hpx::parallel::util::in_out_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type>>
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it

executes the assignments.

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the range from which the elements will be copied from
- **rng2** – Refers to the range to which the elements will be copied to

**Returns** The *uninitialized\_copy* algorithm returns a `hpx::future<in_out_result<InIter, FwdIter>>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type>` otherwise. The *uninitialized\_copy* algorithm returns the input iterator to one past the last element copied from and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Size, typename FwdIter, typename Sent2>
hpx::parallel::util::in_out_result<InIter, FwdIter> uninitialized_copy_n(InIter first1, Size count,
                                                               FwdIter first2, Sent2
                                                               last2)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter`.

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements that will be copied from
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The *uninitialized\_copy\_n* algorithm returns `in_out_result<InIter, FwdIter>`. The *uninitialized\_copy\_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2, typename Sent2>
```

`parallel::util::detail::algorithm_result<ExPolicy, parallel::util::in_out_result<FwdIter1, FwdIter2>>::type uninitialized`

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel `uninitialized_copy_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `uninitialized_copy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter2.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements that will be copied from
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **first2** – Refers to the beginning of the destination range.
- **last1** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The `uninitialized_copy_n` algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `uninitialized_copy_n` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/container\_algorithms/uninitialized\_default\_construct.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename FwdIter, typename Sent>
FwdIter uninitialized_default_construct(FwdIter first, Sent last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.

**Returns** The *uninitialized\_default\_construct* algorithm returns a returns *FwdIter*. The *uninitialized\_default\_construct* algorithm returns the output iterator to the element in the range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Sent>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_default_construct(ExPolicy
&&policy,
FwdIter
first,
Sent
last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.

**Returns** The *uninitialized\_default\_construct* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_default\_construct* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **Rng**>  
*hpx::traits::range\_traits<Rng>::iterator\_type uninitialized\_default\_construct(Rng &&rng)*

Constructs objects of type typename *iterator\_traits<ForwardIt> ::value\_type* in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters rng** – Refers to the range to which will be default constructed.

**Returns** The *uninitialized\_default\_construct* algorithm returns a *hpx::future<ForwardIt> ::value\_type*. The *uninitialized\_default\_construct* algorithm returns the output iterator to the element in the range, one past the last element constructed.

template<typename **ExPolicy**, typename **Rng**>  
*parallel::util::detail::algorithm\_result<ExPolicy, typename hpx::traits::range\_traits<Rng>::iterator\_type>::type uninitialized\_default\_construct(ExPolicy, Rng &&rng)*

Constructs objects of type typename *iterator\_traits<ForwardIt> ::value\_type* in the uninitialized stor-

age designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the range to which the value will be default constructed

**Returns** The *uninitialized\_default\_construct* algorithm returns a `hpx::future<typename hpx::traits::range_traits<Rng> ::iterator_type>`, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `typename hpx::traits::range_traits<Rng>::iterator_type` otherwise. The *uninitialized\_default\_construct* algorithm returns the output iterator to the element in the range, one past the last element constructed.

template<typename **FwdIter**, typename **Size**>  
`FwdIter uninitialized_default_construct_n(FwdIter first, Size count)`

Constructs objects of type `typename iterator_traits<ForwardIt> ::value_type` in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_default\_construct\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_default\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Size>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_default_construct_n(ExPolicy
    &&policy,
    FwdIter
    first,
    Size
    count)
```

Constructs objects of type `typename iterator_traits<ForwardIt> ::value_type` in the uninitialized storage designated by the range `[first, first + count]` by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_default_construct_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `uninitialized_default_construct_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply `f` to.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

**Returns** The `uninitialized_default_construct_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `uninitialized_default_construct_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

## hpx/parallel/container\_algorithms/uninitialized\_fill.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename FwdIter, typename Sent, typename T>
FwdIter uninitialized_fill(FwdIter first, Sent last, T const &value)
```

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

The assignments in the ranges *uninitialized\_fill* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for **FwdIter**.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill* algorithm returns a returns *FwdIter*. The *uninitialized\_fill* algorithm returns the output iterator to the element in the range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter, typename Sent>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_fill(ExPolicy
&&policy,
FwdIter first,
Sent last, T
const &value)
```

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_fill* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_fill* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill* algorithm returns a returns *FwdIter*. The *uninitialized\_fill* algorithm returns the output iterator to the element in the range, one past the last element copied.

template<typename **Rng**, typename **T**>

*hpx::traits::range\_traits<Rng>::iterator\_type uninitialized\_fill(**Rng** &&**rng**, **T** const &**value**)*

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_fill* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **rng** – Refers to the range to which the value will be filled
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill* algorithm returns a returns *hpx::traits::range\_traits<Rng>::iterator\_type*. The *uninitialized\_fill* algorithm returns the output iterator to the element in the range, one past the last element copied.

template<typename **ExPolicy**, typename **Rng**, typename **T**>

*parallel::util::detail::algorithm\_result<ExPolicy, typename hpx::traits::range\_traits<Rng>::iterator\_type>::type uninitialized\_fill*

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_fill* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_fill* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the range to which the value will be filled
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill* algorithm returns a *hpx::future<typename hpx::traits::range\_traits<Rng>::iterator\_type>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *typename hpx::traits::range\_traits<Rng>::iterator\_type* otherwise. The *uninitialized\_fill* algorithm returns the iterator to one past the last element filled in the range.

```
template<typename FwdIter, typename Size, typename T>
FwdIter uninitialized_n(FwdIter first, Size count, T const &value)
```

Copies the given *value* value to the first *count* elements in an uninitialized memory area beginning at *first*. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_fill\_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
```

```
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_fill_n(ExPolicy  
    &&policy,  
    FwdIter  
    first, Size  
    count, T  
    const  
    &value)
```

Copies the given *value* value to the first *count* elements in an uninitialized memory area beginning at *first*. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The *uninitialized\_fill\_n* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_fill\_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

## hpx/parallel/container\_algorithms/uninitialized\_move.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

## Functions

```
template<typename InIter, typename Sent1, typename FwdIter, typename Sent2>
hpx::parallel::util::in_out_result<InIter, FwdIter> uninitialized_move(InIter first1, Sent1 last1,
                                                                     FwdIter first2, Sent2 last2)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter2.

### Parameters

- **first1** – Refers to the beginning of the sequence of elements that will be moved from
- **last1** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The *uninitialized\_move* algorithm returns an *in\_out\_result<InIter, FwdIter>*. The *uninitialized\_move* algorithm returns an input iterator to one past the last element moved from and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2>
parallel::util::detail::algorithm_result<ExPolicy, parallel::util::in_out_result<FwdIter1, FwdIter2>>::type uninitialized
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter2.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements that will be moved from
- **last1** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The *uninitialized\_move* algorithm returns a *hpx::future<in\_out\_result<InIter, FwdIter>>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *in\_out\_result<InIter, FwdIter>* otherwise. The *uninitialized\_move* algorithm returns an input iterator to one past the last element moved from and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename Rng1, typename Rng2>
hpx::parallel::util::in_out_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type> uninitialized_move(hpx::parallel::util::in_out_result<InIter, FwdIter> &result, InIter first1, InIter last1, FwdIter first2, FwdIter last2, hpx::execution::policy policy = hpx::execution::seq);
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

**Parameters**

- **rng1** – Refers to the range from which the elements will be moved from
- **rng2** – Refers to the range to which the elements will be moved to

**Returns** The *uninitialized\_move* algorithm returns an *in\_out\_result*<typename hpx::traits::range\_traits<Rng1>::iterator\_type, typename hpx::traits::range\_traits<Rng2>::iterator\_type>. The *uninitialized\_move* algorithm returns an input iterator to one past the last element moved from and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename Rng1, typename Rng2>
parallel::util::detail::algorithm_result<ExPolicy, hpx::parallel::util::in_out_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type>>
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the range from which the elements will be moved from
- **rng2** – Refers to the range to which the elements will be moved to

**Returns** The *uninitialized\_move* algorithm returns a *hpx::future*<*in\_out\_result*<*InIter*, *FwdIter*>>, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *in\_out\_result*< typename hpx::traits::range\_traits<Rng1>::iterator\_type , typename hpx::traits::range\_traits<Rng2>::iterator\_type > otherwise. The *uninitialized\_move* algorithm returns the input iterator to one past the last element moved from and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename InIter, typename Size, typename FwdIter, typename Sent2>
hpx::parallel::util::in_out_result<InIter, FwdIter> uninitialized_move_n(InIter first1, Size count,
                                                               FwdIter first2, Sent2
                                                               last2)
```

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* movements, if *count* > 0, no move operations otherwise.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements that will be moved from
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The *uninitialized\_move\_n* algorithm returns *in\_out\_result<InIter, FwdIter>*. The *uninitialized\_move\_n* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2, typename
Sent2>
parallel::util::detail::algorithm_result<ExPolicy, parallel::util::in_out_result<FwdIter1, FwdIter2>>::type uninitialized
```

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* movements, if *count* > 0, no move operations otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter2.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements that will be moved from
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **first2** – Refers to the beginning of the destination range.
- **last1** – Refers to sentinel value denoting the end of the second range the algorithm will be applied to.

**Returns** The *uninitialized\_move\_n* algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_move\_n* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

## [hpx/parallel/container\\_algorithms/uninitialized\\_value\\_construct.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

#### Functions

```
template<typename FwdIter, typename Sent>
FwdIter uninitialized_value_construct(FwdIter first, Sent last)
```

Constructs objects of type `typename iterator_traits<ForwardIt> ::value_type` in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.

**Returns** The *uninitialized\_value\_construct* algorithm returns a returns *FwdIter*. The *uninitialized\_value\_construct* algorithm returns the output iterator to the element in the range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Sent>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_value_construct(ExPolicy
    &&policy,
    FwdIter
    first,
    Sent
    last)
```

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.

**Returns** The *uninitialized\_value\_construct* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_value\_construct* algorithm returns the iterator to the element in the source range, one past the last element constructed.

---

template<typename **Rng**>  
*hpx::traits::range\_traits<Rng>::iterator\_type uninitialized\_value\_construct(**Rng** &&rng)*

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

**Template Parameters** **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters** **rng** – Refers to the range to which will be value constructed.

**Returns** The *uninitialized\_value\_construct* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_value\_construct* algorithm returns the output iterator to the element in the range, one past the last element constructed.

template<typename **ExPolicy**, typename **Rng**>

*parallel::util::detail::algorithm\_result<ExPolicy, typename hpx::traits::range\_traits<Rng>::iterator\_type>::type uninitialized\_value\_construct(**ExPolicy** policy, **Rng** rng)*

Constructs objects of type typename iterator\_traits<ForwardIt> ::value\_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **rng** – Refers to the range to which the value will be value consumed

**Returns** The *uninitialized\_value\_construct* algorithm returns a *hpx::future<typename hpx::traits::range\_traits<Rng> ::iterator\_type>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *typename hpx::traits::range\_traits<Rng>::iterator\_type* otherwise. The *uninitialized\_value\_construct* algorithm returns the output iterator to the element in the range, one past the last element constructed.

template<typename **FwdIter**, typename **Size**>

*FwdIter* **uninitialized\_value\_construct\_n**(*FwdIter* first, *Size* count)

Constructs objects of type *typename iterator\_traits<ForwardIt> ::value\_type* in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_value\_construct\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_value\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>

*parallel::util::detail::algorithm\_result<ExPolicy, FwdIter>::type* **uninitialized\_value\_construct\_n**(*ExPolicy*  
    &&policy,  
    *FwdIter*  
    first,  
    *Size*  
    count)

Constructs objects of type *typename iterator\_traits<ForwardIt> ::value\_type* in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns** The *uninitialized\_value\_construct\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_value\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

## hpx/parallel/container\_algorithms/unique.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

#### Functions

```
template<typename FwdIter, typename Sent, typename Pred, typename Proj>
subrange_t<FwdIter, Sent> unique(FwdIter first, Sent last, Pred &&pred, Proj &&proj)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal\_to<>
- **Proj** – The type of an optional projection function. This defaults to util::projection\_identity

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique* algorithm returns *subrange\_t*<*FwdIter*, *Sent*>. The *unique* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred, typename Proj>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type unique(ExPolicy
    &&policy,
    FwdIter
    first, Sent
    last, Pred
    &&pred,
    Proj
    &&proj)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique* algorithm returns *subrange\_t*<*FwdIter*, *Sent*>. The *unique* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange.

```
template<typename Rng, typename Pred, typename Proj>
subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>> unique(Rng
    &&rng,
    Pred
    &&pred,
    Proj
    &&proj)
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range *rng* and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel *unique* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than N assignments, exactly N - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*, where N = `std::distance(begin(rng), end(rng))`.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::equal_to<>`

- **Proj** – The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns** The *unique* algorithm returns `subrange_t<typename hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>>`. The *unique* algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange.

## hpx/parallel/util/low\_level.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **parallel**

        namespace **util**

### Functions

```
template<typename Value, typename ...Args>
inline void construct_object(Value *ptr, Args&&... args)
```

create an object in the memory specified by ptr

**Template Parameters**

- **Value** – : typename of the object to create
- **Args** – : parameters for the constructor

**Parameters**

- **ptr** – [in] : pointer to the memory where to create the object
- **args** – [in] : arguments to the constructor

```
template<typename Value>
```

```
inline void destroy_object(Value *ptr)
```

destroy an object in the memory specified by ptr

**Template Parameters** **Value** – : typename of the object to create

**Parameters** **ptr** – [in] : pointer to the object to destroy

```
template<typename Iter, typename Sent>
```

---

```
inline void init(Iter first, Sent last, typename std::iterator_traits<Iter>::value_type &val)
```

Initialize a range of objects with the object val moving across them

**Parameters**

- **r** – [in] : range of elements not initialized
- **val** – [in] : object used for the initialization

**Returns** range initialized

```
template<typename Value, typename ...Args>
```

```
inline void construct(Value *ptr, Args&&... args)
```

create an object in the memory specified by ptr

**Template Parameters**

- **Value** – : typename of the object to create
- **Args** – : parameters for the constructor

**Parameters**

- **ptr** – [in] : pointer to the memory where to create the object
- **args** – [in] : arguments to the constructor

```
template<typename Iter1, typename Sent1, typename Iter2>
```

```
inline Iter2 init_move(Iter2 it_dest, Iter1 first, Sent1 last)
```

Move objects.

**Template Parameters**

- **Iter** – : iterator to the elements
- **Value** – : typename of the object to create

**Parameters**

- **itdest** – [in] : iterator to the final place of the objects
- **R** – [in] : range to move

```
template<typename Iter, typename Sent, typename Value = typename std::iterator_traits<Iter>::value_type>
```

```
inline Value *uninit_move(Value *ptr, Iter first, Sent last)
```

Move objects to uninitialized memory.

**Template Parameters**

- **Iter** – : iterator to the elements
- **Value** – : typename of the object to construct

**Parameters**

- **ptr** – [in] : pointer to the memory where to create the object
- **R** – [in] : range to move

```
template<typename Iter, typename Sent>
```

```
inline void destroy(Iter first, Sent last)
```

Move objects to uninitialized memory.

**Template Parameters**

- **Iter** – : iterator to the elements
- **Value** – : typename of the object to construct

**Parameters**

- **ptr** – [in] : pointer to the memory where to construct the object
- **R** – [in] : range to move

```
template<typename Iter1, typename Sent1, typename Iter2, typename Compare>
```

```
inline Iter2 full_merge(Iter1 buf1, Sent1 end_buf1, Iter1 buf2, Sent1 end_buf2, Iter2 buf_out,  
                         Compare comp)
```

Merge two contiguous buffers pointed by buf1 and buf2 , and put in the buffer pointed by buf\_out.

**Parameters**

- **buf1** – [in] : iterator to the first element in the first buffer
- **end\_buf1** – [in] : final iterator of first buffer

- **buf2 – [in]** : iterator to the first iterator to the second buffer
- **end\_buf2 – [in]** : final iterator of the second buffer
- **buf\_out – [in]** : buffer where move the elements merged
- **comp – [in]** : comparison object

```
template<typename Iter, typename Sent, typename Value, typename Compare>
inline Value *uninit_full_merge(Iter first1, Sent last1, Iter first2, Sent last2, Value *it_out,
                               Compare comp)
```

Merge two contiguous buffers pointed by first1 and first2 , and put in the uninitialized buffer pointed by it\_out.

#### Parameters

- **first1 – [in]** : iterator to the first element in the first buffer
- **last – [in]** : last iterator of the first buffer
- **first2 – [in]** : iterator to the first element to the second buffer
- **last2 – [in]** : final iterator of the second buffer
- **it\_out – [in]** : uninitialized buffer where move the elements merged
- **comp – [in]** : comparison object

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
inline Iter2 half_merge(Iter1 buf1, Sent1 end_buf1, Iter2 buf2, Sent2 end_buf2, Iter2 buf_out,
                       Compare comp)
```

: Merge two buffers. The first buffer is in a separate memory. The second buffer have a empty space before buf2 of the same size than the (end\_buf1 - buf1)

---

#### Remark

The elements pointed by Iter1 and Iter2 must be the same

---

#### Parameters

- **buf1 – [in]** : iterator to the first element of the first buffer
- **end\_buf1 – [in]** : iterator to the last element of the first buffer
- **buf2 – [in]** : iterator to the first element of the second buffer
- **end\_buf2 – [in]** : iterator to the last element of the second buffer
- **buf\_out – [in]** : iterator to the first element to the buffer where put the result
- **comp – [in]** : object for Compare two elements of the type pointed by the Iter1 and Iter2

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
         typename Compare>
bool in_place_merge_uncontiguous(Iter1 src1, Sent1 end_src1, Iter2 src2, Sent2 end_src2,
                                 Iter3 aux, Compare comp)
```

Merge two non contiguous buffers, placing the results in the buffers for to do this use an auxiliary buffer pointed by aux

#### Parameters

- **src1 – [in]** : iterator to the first element of the first buffer
- **end\_src1 – [in]** : last iterator of the first buffer
- **src2 – [in]** : iterator to the first element of the second buffer
- **end\_src2 – [in]** : last iterator of the second buffer
- **aux – [in]** : iterator to the first element of the auxiliary buffer
- **comp – [in]** : object for to Compare elements

#### Throws

```
template<typename Iter1, typename Sent1, typename Iter2, typename Compare>
```

---

inline bool **in\_place\_merge**(*Iter1* src1, *Iter1* src2, *Sent1* end\_src2, *Iter2* buf, *Compare* comp)

: merge two contiguous buffers, using an auxiliary buffer pointed by buf

**Parameters**

- **src1** – [in] iterator to the first position of the first buffer
- **src2** – [in] final iterator of the first buffer and first iterator of the second buffer
- **end\_src2** – [in] : final iterator of the second buffer
- **buf** – [in] : iterator to buffer used as auxiliary memory
- **comp** – [in] : object for to Compare elements

**Throws**

## hpx/parallel/util/merge\_four.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parallel**

namespace **util**

### Functions

template<typename **Iter**, typename **Sent**, typename **Compare**>

inline bool **less\_range**(*Iter* it1, *std*::uint32\_t pos1, *Sent* it2, *std*::uint32\_t pos2, *Compare* comp)

Compare the elements pointed by it1 and it2, and if they are equals, compare their position, doing a stable comparison.

**Parameters**

- **it1** – [in] : iterator to the first element
- **pos1** – [in] : position of the object pointed by it1
- **it2** – [in] : iterator to the second element
- **pos2** – [in] : position of the element pointed by it2
- **comp** – [in] : comparison object

**Returns** result of the comparison

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>

*util*::range<*Iter1*, *Sent1*> **full\_merge4**(*util*::range<*Iter1*, *Sent1*> &rdest, *util*::range<*Iter2*, *Sent2*> vrangle\_input[4], *std*::uint32\_t nrangle\_input, *Compare* comp)

Merge four ranges.

**Parameters**

- **dest** – [in] range where move the elements merged. Their size must be greater or equal than the sum of the sizes of the ranges in the array R
- **R** – [in] : array of ranges to merge
- **nrangle\_input** – [in] : number of ranges in R
- **comp** – [in] : comparison object

**Returns** range with all the elements move with the size adjusted

template<typename **Value**, typename **Iter**, typename **Sent**, typename **Compare**>

```
util::range<Value*> uninit_full_merge4(util::range<Value*> const &dest, util::range<Iter,
                                          Sent> vrange_input[4], std::uint32_t nrange_input,
                                          Compare comp)
```

Merge four ranges and put the result in uninitialized memory.

#### Parameters

- **dest** – [in] range where create and move the elements merged. Their size must be greater or equal than the sum of the sizes of the ranges in the array R
- **R** – [in] : array of ranges to merge
- **nrange\_input** – [in] : number of ranges in vrange\_input
- **comp** – [in] : comparison object

**Returns** range with all the elements move with the size adjusted

## hpx/parallel/util/merge\_vector.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parallel**

namespace **util**

### Functions

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
         Compare>
void merge_level4(util::range<Iter1, Sent1> dest, std::vector<util::range<Iter2, Sent2>>
                  &v_input, std::vector<util::range<Iter1, Sent1>> &v_output, Compare comp)
```

Merge the ranges in the vector v\_input using full\_merge4. The v\_output vector is used as auxiliary memory in the internal process. The final results is in the dest range. All the ranges of v\_output are inside the range dest

#### Parameters

- **dest** – [in] : range where move the elements merged
- **v\_input** – [in] : vector of ranges to merge
- **v\_output** – [in] : vector of ranges obtained
- **comp** – [in] : comparison object

**Returns** range with all the elements moved

```
template<typename Value, typename Iter, typename Sent, typename Compare>
void uninit_merge_level4(util::range<Value*> dest, std::vector<util::range<Iter, Sent>>
                        &v_input, std::vector<util::range<Value*>> &v_output, Compare
                        comp)
```

Merge the ranges over uninitialized memory,in the vector v\_input using full\_merge4. The v\_output vector is used as auxiliary memory in the internal process. The final results is in the dest range. All the ranges of v\_output are inside the range dest

#### Parameters

- **dest** – [in] : range where move the elements merged
- **v\_input** – [in] : vector of ranges to merge
- **v\_output** – [in] : vector of ranges obtained
- **comp** – [in] : comparison object

**Returns** range with all the elements moved

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
util::range<Iter2, Sent2> merge_vector4(util::range<Iter1, Sent1> range_input, util::range<Iter2,
                                          Sent2> range_output, std::vector<util::range<Iter1,
                                          Sent1>> &v_input, std::vector<util::range<Iter2,
                                          Sent2>> &v_output, Compare comp)
```

Merge the ranges in the vector v\_input using merge\_level4. The v\_output vector is used as auxiliary memory in the internal process. The final results are in the range range\_output. All the ranges of v\_output are inside the range range\_output. All the ranges of v\_input are inside the range range\_input.

**Parameters** `range_input` – [in] : range including all the ranges of v\_input  
**Param**

## hpx/parallel/util/nbits.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## namespace **hpx**

namespace **parallel**

## namespace **util**

## Functions

```
inline constexpr std::uint32_t nbits32(std::uint32_t num) noexcept
```

Obtain the number of bits equal or greater than num.

### Parameters num

**Throws** none –

**Returns** Number of bits

ine constexpr `std::uint32_t` **nbits64**(`std::uint64_t` num)

Obtain the number of bits equal or greater than m

## Parameters num

**Throws** none –

## hpx/parallel/util/range.hpp

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

    namespace **parallel**

        namespace **util**

### Typedefs

```
template<typename Iterator, typename Sentinel = Iterator>
using range = hpx::util::iterator_range<Iterator, Sentinel>
```

### Functions

```
template<typename Iter, typename Sent>
range<Iter, Sent> concat(range<Iter, Sent> const &it1, range<Iter, Sent> const &it2)
    concatenate two contiguous ranges
    Parameters
        • it1 – [in] : first range
        • it2 – [in] : second range
    Returns range resulting of the concatenation

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2>
inline range<Iter2, Iter2> init_move(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const &src)
    Move objects from the range src to dest.
    Parameters
        • dest – [in] : range where move the objects
        • src – [in] : range from where move the objects
    Returns range with the objects moved and the size adjusted

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2>
inline range<Iter2, Sent2> uninit_move(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const &src)
    Move objects from the range src creating them in dest.
    Parameters
        • dest – [in] : range where move and create the objects
        • src – [in] : range from where move the objects
    Returns range with the objects moved and the size adjusted

template<typename Iter, typename Sent>
inline void destroy_range(range<Iter, Sent> r)
    destroy a range of objects
    Parameters r – [in] : range to destroy

template<typename Iter, typename Sent>
```

---

```
inline range<Iter, Sent> init(range<Iter, Sent> const &r, typename
                           std::iterator_traits<Iter>::value_type &val)

initialize a range of objects with the object val moving across them

Parameters

- r – [in] : range of elements not initialized
- val – [in] : object used for the initialization

Returns range initialized

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
Compare>
inline bool is_mergeable(range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2,
                        Compare comp)

: indicate if two ranges have a possible merge

Parameters

- src1 – [in] : first range
- src2 – [in] : second range
- comp – [in] : object for to compare elements

Throws

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
typename Sent3, typename Compare>
inline range<Iter3, Sent3> full_merge(range<Iter3, Sent3> const &dest, range<Iter1, Sent1> const
                                         &src1, range<Iter2, Sent2> const &src2, Compare comp)

Merge two contiguous ranges src1 and src2 , and put the result in the range dest, returning the
range merged.

Parameters

- dest – [in] : range where locate the elements merged. the size of dest must be greater or
equal than the sum of the sizes of src1 and src2
- src1 – [in] : first range to merge
- src2 – [in] : second range to merge
- comp – [in] : comparison object

Returns range with the elements merged and the size adjusted

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Value,
typename Compare>
inline range<Value*> uninit_full_merge(const range<Value*> &dest, range<Iter1, Sent1> const
                                         &src1, range<Iter2, Sent2> const &src2, Compare
                                         comp)

Merge two contiguous ranges src1 and src2 , and create and move the result in the uninitialized
range dest, returning the range merged.

Parameters

- dest – [in] : range where locate the elements merged. the size of dest must be greater
or equal than the sum of the sizes of src1 and src2. Initially is uninitialized memory
- src1 – [in] : first range to merge
- src2 – [in] : second range to merge
- comp – [in] : comparison object

Returns range with the elements merged and the size adjusted

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
Compare>
inline range<Iter2, Sent2> half_merge(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const
                                         &src1, range<Iter2, Sent2> const &src2, Compare comp)

: Merge two buffers. The first buffer is in a separate memory

Parameters
```

- **dest** – [in] : range where finish the two buffers merged
  - **src1** – [in] : first range to merge in a separate memory
  - **src2** – [in] : second range to merge, in the final part of the range where deposit the final results
  - **comp** – [in] : object for compare two elements of the type pointed by the Iter1 and Iter2
- Returns** : range with the two buffers merged

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
         typename Sent3, typename Compare>
bool in_place_merge_uncontiguous(range<Iter1, Sent1> const &src1, range<Iter2, Sent2>
                                 const &src2, range<Iter3, Sent3> &aux, Compare comp)
```

: merge two non contiguous buffers src1 , src2, using the range aux as auxiliary memory

**Parameters**

- **src1** – [in] : first range to merge
- **src2** – [in] : second range to merge
- **aux** – [in] : auxiliary range used in the merge
- **comp** – [in] : object for to compare elements

**Throws**

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
         Compare>
inline range<Iter1, Sent1> in_place_merge(range<Iter1, Sent1> const &src1, range<Iter1, Sent1>
                                             const &src2, range<Iter2, Sent2> &buf, Compare
                                             comp)
```

: merge two contiguous buffers ( src1, src2) using buf as auxiliary memory

**Parameters**

- **src1** – [in] : first range to merge
- **src2** – [in] : second range to merge
- **buf** – [in] : auxiliary memory used in the merge
- **comp** – [in] : object for to compare elements

**Throws**

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
         Compare>
inline void merge_flow(range<Iter1, Sent1> rng1, range<Iter2, Sent2> rbuf, range<Iter1, Sent1>
                      rng2, Compare cmp)
```

: merge two contiguous buffers

**Template Parameters**

- **Iter** – : iterator to the elements
- **compare** – : object for to compare two elements pointed by Iter iterators

**Parameters**

- **first** – [in] : iterator to the first element
- **last** – [in] : iterator to the element after the last in the range
- **comp** – [in] : object for to compare elements

**Throws**

## hpx/parallel/util/result\_types.hpp

namespace **hpx**

namespace **assertion**

### hpx/modules/assertion.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## Defines

### HPX\_ASSERT(expr)

This macro asserts that *expr* evaluates to true.

If *expr* evaluates to false, The source location and *msg* is being printed along with the expression and additional. Afterwards the program is being aborted. The assertion handler can be customized by calling `hpx::assertion::set_assertion_handler()`.

Asserts are enabled if *HPX\_DEBUG* is set. This is the default for *CMAKE\_BUILD\_TYPE=Debug*

#### Parameters

- **expr** – The expression to assert on. This can either be an expression that's convertible to bool or a callable which returns bool
- **msg** – The optional message that is used to give further information if the assert fails. This should be convertible to a `std::string`

### HPX\_ASSERT\_MSG(expr, msg)

See also:

`HPX_ASSERT`

---

namespace **hpx**

namespace **assertion**

### Typedefs

```
using assertion_handler = void (*)(hpx::source_location const &loc, const char *expr, std::string const &msg)
```

The signature for an assertion handler.

### Functions

```
void set_assertion_handler(assertion_handler handler)
```

Set the assertion handler to be used within a program. If the handler has been set already once, the call to this function will be ignored.

---

**Note:** This function is not thread safe

---

## async\_base

See *Public API* for a list of names and headers that are part of the public HPX API.

### **hpx/async\_base/launch\_policy.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

```
struct launch : public detail::policy_holder<>
```

```
#include <launch_policy.hpp> Launch policies for hpx::async etc.
```

### Public Functions

```
inline constexpr launch() noexcept
```

Default constructor. This creates a launch policy representing all possible launch modes

```
inline constexpr launch(detail::async_policy p) noexcept
```

Create a launch policy representing asynchronous execution.

```
inline constexpr launch(detail::fork_policy p) noexcept
```

Create a launch policy representing asynchronous execution. The new thread is executed in a preferred way

```
inline constexpr launch(detail::sync_policy p) noexcept
```

Create a launch policy representing synchronous execution.

```
inline constexpr launch(detail::deferred_policy p) noexcept
    Create a launch policy representing deferred execution.

inline constexpr launch(detail::apply_policy p) noexcept
    Create a launch policy representing fire and forget execution.

template<typename F>
inline constexpr launch(detail::select_policy<F> const &p) noexcept
    Create a launch policy representing fire and forget execution.

template<typename Launch, typename Enable =
    std::enable_if_t<hpx::traits::is_launch_policy_v<Launch>>>
inline constexpr launch(Launch l, threads::thread_priority priority, threads::thread_stacksize stacksize,
    threads::thread_schedule_hint hint) noexcept
```

## Public Static Attributes

static const detail::async\_policy **async**

Predefined launch policy representing asynchronous execution.

static const detail::fork\_policy **fork**

Predefined launch policy representing asynchronous execution. The new thread is executed in a preferred way

static const detail::sync\_policy **sync**

Predefined launch policy representing synchronous execution.

static const detail::deferred\_policy **deferred**

Predefined launch policy representing deferred execution.

static const detail::apply\_policy **apply**

Predefined launch policy representing fire and forget execution.

static const detail::select\_policy\_generator **select**

Predefined launch policy representing delayed policy selection.

## Friends

```
inline friend launch tag_invoke(hpx::execution::experimental::with_priority_t, launch const &policy,
    threads::thread_priority priority) noexcept
```

```
inline friend constexpr friend hpx::threads::thread_priority tag_invoke (hpx::execution::experimental::with_priority_t, launch const &policy)
    launch const &policy) noexcept
```

```
inline friend launch tag_invoke(hpx::execution::experimental::with_stacksize_t, launch const &policy,
    threads::thread_stacksize stacksize) noexcept
```

```

inline friend constexpr friend hpx::threads::thread_stacksize tag_invoke (hpx::execution::experimental::with_hint_t, launch const &policy) noexcept

inline friend launch tag_invoke(hpx::execution::experimental::with_hint_t, launch const &policy,
           threads::thread_schedule_hint hint) noexcept

inline friend constexpr friend hpx::threads::thread_schedule_hint tag_invoke (hpx::execution::experimental::with_hint_t, launch const &policy) noexcept

```

## async\_combinators

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### `hpx/async_combinators/split_future.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

#### Functions

```

template<typename ...Ts>
inline tuple<future<Ts>...> split_future(future<tuple<Ts...>> &&f)

```

The function `split_future` is an operator allowing to split a given future of a sequence of values (any tuple, std::pair, or std::array) into an equivalent container of futures where each future represents one of the values from the original future. In some sense this function provides the inverse operation of `when_all`.

---

**Note:** The following cases are special:

```

tuple<future<void> > split_future(future<tuple<>> && f);
array<future<void>, 1> split_future(future<array<T, 0>> && f);

```

---

here the returned futures are directly representing the futures which were passed to the function.

**Parameters** `f` – [in] A future holding an arbitrary sequence of values stored in a tuple-like container. This facility supports `hpx::tuple<>`, `std::pair<T1, T2>`, and `std::array<T, N>`

**Returns** Returns an equivalent container (same container type as passed as the argument) of futures, where each future refers to the corresponding value in the input parameter. All of the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

```

template<typename T>
inline std::vector<future<T>> split_future(future<std::vector<T>> &&f, std::size_t size)

```

The function `split_future` is an operator allowing to split a given future of a sequence of values (any std::vector) into a std::vector of futures where each future represents one of the values from the original std::vector. In some sense this function provides the inverse operation of `when_all`.

#### Parameters

- **f** – [in] A future holding an arbitrary sequence of values stored in a std::vector.
- **size** – [in] The number of elements the vector will hold once the input future has become ready

**Returns** Returns a std::vector of futures, where each future refers to the corresponding value in the input parameter. All of the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

## hpx/async\_combinators/wait\_all.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InputIter>
void wait_all(InputIter first, InputIter last)
```

The function *wait\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all* returns after all futures have become ready. All input futures are still valid after *wait\_all* returns.

---

**Note:** The function *wait\_all* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_all\_nothrow* instead.

---

### Parameters

- **first** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_all* should wait.
- **last** – The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_all* should wait.

```
template<typename R>
void wait_all(std::vector<future<R>> &&futures)
```

The function *wait\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all* returns after all futures have become ready. All input futures are still valid after *wait\_all* returns.

---

**Note:** The function *wait\_all* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_all\_nothrow* instead.

---

---

**Parameters `futures`** – A vector or array holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_all* should wait.

```
template<typename R, std::size_t N>
void wait_all(std::array<future<R>, N> &&futures)
```

The function *wait\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all* returns after all futures have become ready. All input futures are still valid after *wait\_all* returns.

---

**Note:** The function *wait\_all* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_all\_nothrow* instead.

**Parameters `futures`** – A vector or array holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_all* should wait.

```
template<typename ...T>
void wait_all(T&&... futures)
```

The function *wait\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all* returns after all futures have become ready. All input futures are still valid after *wait\_all* returns.

---

**Note:** The function *wait\_all* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_all\_nothrow* instead.

**Parameters `futures`** – An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_all* should wait.

```
template<typename InputIter>
void wait_all_n(InputIter begin, std::size_t count)
```

The function *wait\_all\_n* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all\_n* returns after all futures have become ready. All input futures are still valid after *wait\_all\_n* returns.

---

**Note:** The function *wait\_all\_n* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_all\_n\_nothrow* instead.

## Parameters

- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_all\_n* should wait.
- **count** – The number of elements in the sequence starting at *first*.

**Returns** The function *wait\_all\_n* will return an iterator referring to the first element in the input sequence after the last processed element.

## hpx/async\_combinators/wait\_any.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InputIter>
void wait_any(InputIter first, InputIter last)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

---

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_any* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_any* should wait.

```
template<typename R>
void wait_any(std::vector<future<R>> &futures)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

---

---

**Parameters** **futures** – [in] A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_any* should wait.

```
template<typename R, std::size_t N>
void wait_any(std::array<future<R>, N> &futures)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

**Parameters** **futures** – [in] An array holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_any* should wait.

```
template<typename ...T>
void wait_any(T &&... futures)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

**Parameters** **futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_any* should wait.

```
template<typename InputIter>
void wait_any_n(InputIter first, std::size_t count)
```

The function *wait\_any\_n* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any\_n* returns after at least one future has become ready. All input futures are still valid after *wait\_any\_n* returns.

---

**Note:** The function *wait\_any\_n* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_n\_nothrow* instead.

## Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_any\_n* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

## hpx/async\_combinators/wait\_each.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename F, typename Future>
void wait_each(F &&f, std::vector<Future> &&futures)
```

The function *wait\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait\_each* returns after all futures have been become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_each* should wait.

```
template<typename F, typename Iterator>
void wait_each(F &&f, Iterator begin, Iterator end)
```

The function *wait\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait\_each* returns after all futures have been become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.

- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.
- **end** – The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.

```
template<typename F, typename ...T>
void wait_each(F &&f, T&&... futures)
```

The function *wait\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait\_each* returns after all futures have been become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_each* should wait.

```
template<typename F, typename Iterator>
void wait_each_n(F &&f, Iterator begin, std::size_t count)
```

The function *wait\_each* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each\_n* should wait.
- **count** – The number of elements in the sequence starting at *first*.

## hpx/async\_combinators/wait\_some.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InputIter>
void wait_some(std::size_t n, InputIter first, InputIter last)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

---

**Note:** The function *wait\_some* returns after n futures have become ready. All input futures are still valid after *wait\_some* returns.

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the function to return.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.

```
template<typename R>
void wait_some(std::size_t n, std::vector<future<R>> &&futures)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

---

**Note:** The function *wait\_some* returns after n futures have become ready. All input futures are still valid after *wait\_some* returns.

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.

- **futures** – [in] A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_some* should wait.

```
template<typename R, std::size_t N>
void wait_some(std::size_t n, std::array<future<R>, N> &&futures)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_some* returns after *n* futures have become ready. All input futures are still valid after *wait\_some* returns.

---

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] An array holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_some* should wait.

```
template<typename ...T>
void wait_some(std::size_t n, T&&... futures)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_all* returns after *n* futures have become ready. All input futures are still valid after *wait\_some* returns.

---

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_some* should wait.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
template<typename InputIter>
```

```
void wait_some_n(std::size_t n, InputIter first, std::size_t count)
```

The function *wait\_some\_n* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_some\_n* returns after *n* futures have become ready. All input futures are still valid after *wait\_some\_n* returns.

---

**Note:** The function *wait\_some\_n* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_n\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

## [hpx/async\\_combinators/when\\_all.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InputIter, typename Container = vector<future<typename  
std::iterator_traits<InputIter>::value_type>>>  
hpx::future<Container> when_all(InputIter first, InputIter last)
```

The function *when\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** Calling this version of *when\_all* where *first* == *last*, returns a future with an empty container that is immediately ready. Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_all* will not throw an exception, but the futures held in the output collection may.

---

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.

**Returns** Returns a future holding the same list of futures as has been passed to *when\_all*.

- `future<Container<future<R>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename Range>
hpx::future<Range> when_all(Range &&values)
```

The function `when_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** Calling this version of `when_all` where the input container is empty, returns a future with an empty container that is immediately ready. Each future and shared\_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_all` will not throw an exception, but the futures held in the output collection may.

---

**Parameters `values`** – [in] A range holding an arbitrary amount of `future` or `shared_future` objects for which `when_all` should wait.

**Returns** Returns a future holding the same list of futures as has been passed to `when_all`.

- `future<Container<future<R>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type.

```
template<typename ...T>
hpx::future<hpx::tuple<hpx::future<T>...>> when_all(T &&... futures)
```

The function `when_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** Each future and shared\_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_all` will not throw an exception, but the futures held in the output collection may.

---

**Parameters `futures`** – [in] An arbitrary number of `future` or `shared_future` objects, possibly holding different types for which `when_all` should wait.

**Returns** Returns a future holding the same list of futures as has been passed to `when_all`.

- `future<tuple<future<T0>, future<T1>, future<T2>...>>`: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- `future<tuple<>>` if `when_all` is called with zero arguments. The returned future will be initially ready.

```
template<typename InputIter, typename Container = vector<future<typename
std::iterator_traits<InputIter>::value_type>>>
hpx::future<Container> when_all_n(InputIter begin, std::size_t count)
```

The function `when_all_n` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** None of the futures in the input sequence are invalidated.

---

### Parameters

- **begin** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_all\_n* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

**Throws** This – function will throw errors which are encountered while setting up the requested operation only. Errors encountered while executing the operations delivering the results to be stored in the futures are reported through the futures themselves.

**Returns** Returns a future holding the same list of futures as has been passed to *when\_all\_n*.

- *future<Container<future<R>>>*: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output vector will be the same as given by the input iterator.

## hpx/async\_combinators/when\_any.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InputIter, typename Container = vector<future<typename  
std::iterator_traits<InputIter>::value_type>>>  
future<when_any_result<Container>> when_any(InputIter first, InputIter last)
```

The function *when\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_any* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_any* should wait.

**Returns** Returns a *when\_any\_result* holding the same list of futures as has been passed to *when\_any* and an index pointing to a ready future.

- *future<when\_any\_result<Container<future<R>>>>*: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename Range>

---

`future<when_any_result<Range>> when_any(Range &values)`

The function `when_any` is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Parameters** `values` – [in] A range holding an arbitrary amount of `futures` or `shared_future` objects for which `when_any` should wait.

**Returns** Returns a `when_any_result` holding the same list of futures as has been passed to `when_any` and an index pointing to a ready future.

- `future<when_any_result<Container<future<R>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

`template<typename ...T>  
future<when_any_result<tuple<future<T>...>>> when_any(T&&... futures)`

The function `when_any` is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Parameters** `futures` – [in] An arbitrary number of `future` or `shared_future` objects, possibly holding different types for which `when_any` should wait.

**Returns** Returns a `when_any_result` holding the same list of futures as has been passed to `when_any` and an index pointing to a ready future..

- `future<when_any_result<tuple<future<T0>, future<T1>...>>>`: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- `future<when_any_result<tuple<>>>` if `when_any` is called with zero arguments. The returned future will be initially ready.

`template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>>  
future<when_any_result<Container>> when_any_n(InputIter first, std::size_t count)`

The function `when_any_n` is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

---

**Note:** None of the futures in the input sequence are invalidated.

---

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `when_any_n` should wait.
- **count** – [in] The number of elements in the sequence starting at `first`.

**Returns** Returns a `when_any_result` holding the same list of futures as has been passed to `when_any` and an index pointing to a ready future.

- `future<when_any_result<Container<future<R>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

`template<typename Sequence>`

```
struct when_any_result
```

`#include <when_any.hpp>` Result type for *when\_any*, contains a sequence of futures and an index pointing to a ready future.

### Public Members

```
std::size_t index
```

The index of a future which has become ready.

```
Sequence futures
```

The sequence of futures as passed to *hpx::when\_any*

## hpx/async\_combinators/when\_each.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename F, typename Future>
future<void> when_each(F &&f, std::vector<Future> &&futures)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_each* should wait.

**Returns** Returns a future representing the event of all input futures being ready.

```
template<typename F, typename Iterator>
future<Iterator> when_each(F &&f, Iterator begin, Iterator end)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.
- **end** – The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.

**Returns** Returns a future representing the event of all input futures being ready.

```
template<typename F, typename ...Ts>
future<void> when_each(F &&f, Ts&&... futures)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_each* should wait.

**Returns** Returns a future representing the event of all input futures being ready.

```
template<typename F, typename Iterator>
future<Iterator> when_each_n(F &&f, Iterator begin, std::size_t count)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each\_n* should wait.
- **count** – The number of elements in the sequence starting at *first*.

**Returns** Returns a future holding the iterator pointing to the first element after the last one.

## hpx/async\_combinators/when\_some.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InputIter, typename Container = vector<future<typename  
std::iterator_traits<InputIter>::value_type>>>  
future<when_some_result<Container>> when_some(std::size_t n, Iterator first, Iterator last)
```

The function *when\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The future returned by the function *when\_some* becomes ready when at least *n* argument futures have become ready.

---

**Note:** Calling this version of *when\_some* where *first* == *last*, returns a future with an empty container that is immediately ready. Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_some* will not throw an exception, but the futures held in the output collection may.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.

**Returns** Returns a *when\_some\_result* holding the same list of futures as has been passed to *when\_some* and indices pointing to ready futures.

- *future<when\_some\_result<Container<future<R>>>>*: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename Range>

---

`future<when_some_result<Range>> when_some(std::size_t n, Range &&futures)`

The function `when_some` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

---

**Note:** The future returned by the function `when_some` becomes ready when at least `n` argument futures have become ready.

---

**Note:** Each future and shared\_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_some` will not throw an exception, but the futures held in the output collection may.

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] A container holding an arbitrary amount of `future` or `shared_future` objects for which `when_some` should wait.

**Returns** Returns a `when_some_result` holding the same list of futures as has been passed to `when_some` and indices pointing to ready futures.

- `future<when_some_result<Container<future<R>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

`template<typename ...Ts>`

`future<when_some_result<tuple<future<T>...>>> when_some(std::size_t n, Ts&&... futures)`

The function `when_some` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

---

**Note:** The future returned by the function `when_some` becomes ready when at least `n` argument futures have become ready.

---

**Note:** Each future and shared\_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_some` will not throw an exception, but the futures held in the output collection may.

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] An arbitrary number of `future` or `shared_future` objects, possibly holding different types for which `when_some` should wait.

**Returns** Returns a `when_some_result` holding the same list of futures as has been passed to `when_some` and an index pointing to a ready future..

- `future<when_some_result<tuple<future<T0>, future<T1>...>>>`: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- `future<when_some_result<tuple<>>>` if `when_some` is called with zero arguments. The returned future will be initially ready.

```
template<typename InputIter, typename Container = vector<future<typename  
std::iterator_traits<InputIter>::value_type>>>  
future<when_some_result<Container>> when_some_n(std::size_t n, Iterator first, std::size_t count)
```

The function `when_some_n` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

---

**Note:** The future returned by the function `when_some_n` becomes ready when at least `n` argument futures have become ready.

---

---

**Note:** Calling this version of `when_some_n` where `count == 0`, returns a future with the same elements as the arguments that is immediately ready. Possibly none of the futures in that container are ready. Each future and `shared_future` is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_some_n` will not throw an exception, but the futures held in the output collection may.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `when_all` should wait.
- **count** – [in] The number of elements in the sequence starting at `first`.

**Returns** Returns a `when_some_result` holding the same list of futures as has been passed to `when_some` and indices pointing to ready futures.

- `future<when_some_result<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename Sequence>
```

```
struct when_some_result
```

```
#include <when_some.hpp> Result type for when_some, contains a sequence of futures and indices pointing to ready futures.
```

## Public Members

`std::vector<std::size_t> indices`

List of indices of futures that have become ready.

*Sequence* **futures**

The sequence of futures as passed to `hpx::when_some`.

## cache

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/cache/local\_cache.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

namespace **cache**

```
template<typename Key, typename Entry, typename UpdatePolicy = std::less<Entry>, typename
InsertPolicy = policies::always<Entry>, typename CacheStorage = std::map<Key, Entry>,
typename Statistics = statistics::no_statistics>
class local_cache
```

#include <hpx/cache/local\_cache.hpp> The `local_cache` implements the basic functionality needed for a local (non-distributed) cache.

#### Template Parameters

- **Key** – The type of the keys to use to identify the entries stored in the cache
- **Entry** – The type of the items to be held in the cache, must model the `CacheEntry` concept
- **UpdatePolicy** – A (optional) type specifying a (binary) function object used to sort the cache entries based on their ‘age’. The ‘oldest’ entries (according to this sorting criteria) will be discarded first if the maximum capacity of the cache is reached. The default is `std::less<Entry>`. The function object will be invoked using 2 entry instances of the type `Entry`. This type must model the `UpdatePolicy` model.
- **InsertPolicy** – A (optional) type specifying a (unary) function object used to allow global decisions whether a particular entry should be added to the cache or not. The default is `policies::always`, imposing no global insert related criteria on the cache. The

function object will be invoked using the entry instance to be inserted into the cache. This type must model the InsertPolicy model.

- **CacheStorage** – A (optional) container type used to store the cache items. The container must be an associative and STL compatible container. The default is a std::map<Key, Entry>.
- **Statistics** – A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type `statistics::no_statistics` which does not collect any numbers, but provides empty stubs allowing the code to compile.

## Public Types

using **key\_type** = `Key`

using **entry\_type** = `Entry`

using **update\_policy\_type** = `UpdatePolicy`

using **insert\_policy\_type** = `InsertPolicy`

using **storage\_type** = `CacheStorage`

using **statistics\_type** = `Statistics`

using **value\_type** = typename `entry_type`::value\_type

using **size\_type** = typename `storage_type`::size\_type

using **storage\_value\_type** = typename `storage_type`::value\_type

## Public Functions

```
inline local_cache(size_type max_size = 0, update_policy_type const &up =
                    update_policy_type(), insert_policy_type const &ip =
                    insert_policy_type())
```

Construct an instance of a `local_cache`.

### Parameters

- **max\_size** – [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry's `get_size` function.
- **up** – [in] An instance of the `UpdatePolicy` to use for this cache. The default is to use a default constructed instance of the type as defined by the `UpdatePolicy` template parameter.
- **ip** – [in] An instance of the `InsertPolicy` to use for this cache. The default is to use a default constructed instance of the type as defined by the `InsertPolicy` template parameter.

```
local_cache(local_cache &&other) = default
```

```
inline constexpr size_type size() const noexcept
```

Return current size of the cache.

**Returns** The current size of this cache instance.

```
inline constexpr size_type capacity() const noexcept
```

Access the maximum size the cache is allowed to grow to.

---

**Note:** The unit of this value is usually determined by the unit of the return values of the entry's function *entry::get\_size*.

---

**Returns** The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

```
inline bool reserve(size_type max_size)
```

Change the maximum size this cache can grow to.

**Parameters** **max\_size** – [in] The new maximum size this cache will be allowed to grow to.

**Returns** This function returns *true* if successful. It returns *false* if the new *max\_size* is smaller than the current limit and the cache could not be shrunk to the new maximum size.

```
inline bool holds_key(key_type const &k) const
```

Check whether the cache currently holds an entry identified by the given key.

---

**Note:** This function does not call the entry's function *entry::touch*. It just checks if the cache contains an entry corresponding to the given key.

---

**Parameters** **k** – [in] The key for the entry which should be looked up in the cache.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool get_entry(key_type const &k, key_type &realkey, entry_type &val)
```

Get a specific entry identified by the given key.

---

**Note:** The function will call the entry's *entry::touch* function if the value corresponding to the provided key is found in the cache.

---

**Parameters**

- **k** – [in] The key for the entry which should be retrieved from the cache.
- **val** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool get_entry(key_type const &k, entry_type &val)
```

Get a specific entry identified by the given key.

---

**Note:** The function will call the entry's *entry::touch* function if the value corresponding to the provided key is found in the cache.

---

**Parameters**

- **k** – [in] The key for the entry which should be retrieved from the cache.
- **val** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

---

inline bool **get\_entry**(*key\_type* const &k, *value\_type* &val)

Get a specific entry identified by the given key.

---

**Note:** The function will call the entry's *entry::touch* function if the value corresponding to the provided is found in the cache.

**Parameters**

- **k** – [in] The key for the entry which should be retrieved from the cache
- **val** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding value.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

---

inline bool **insert**(*key\_type* const &k, *value\_type* const &val)

Insert a new element into this cache.

---

**Note:** This function invokes both, the insert policy as provided to the constructor and the function *entry::insert* of the newly constructed entry instance. If either of these functions returns false the key/value pair doesn't get inserted into the cache and the *insert* function will return *false*. Other reasons for this function to fail (return *false*) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

**Parameters**

- **k** – [in] The key for the entry which should be added to the cache.
- **value** – [in] The value which should be added to the cache.

**Returns** This function returns *true* if the entry has been successfully added to the cache, otherwise it returns *false*.

---

inline bool **insert**(*key\_type* const &k, *value\_type* &&val)

template<typename **Entry\_**, *std*::enable\_if\_t<*std*::is\_convertible\_v<*std*::decay\_t<**Entry\_**>, *entry\_type*>, int> = 0>

inline bool **insert**(*key\_type* const &k, *Entry\_* &&e)

Insert a new entry into this cache.

---

**Note:** This function invokes both, the insert policy as provided to the constructor and the function *entry::insert* of the provided entry instance. If either of these functions returns false the key/value pair doesn't get inserted into the cache and the *insert* function will return *false*. Other reasons for this function to fail (return *false*) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

**Parameters**

- **k** – [in] The key for the entry which should be added to the cache.

- **value** – [in] The entry which should be added to the cache.

**Returns** This function returns *true* if the entry has been successfully added to the cache, otherwise it returns *false*.

```
template<typename Value, std::enable_if_t<std::is_convertible_v<std::decay_t<Value>,  
value_type>, int> = 0>  
inline bool update(key_type const &k, Value &&val)
```

Update an existing element in this cache.

---

**Note:** The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

#### Parameters

- **k** – [in] The key for the value which should be updated in the cache.
- **value** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

**Returns** This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename F, typename Value, typename =  
std::enable_if_t<std::is_convertible_v<std::decay_t<Value>, value_type>>>  
inline bool update_if(key_type const &k, Value &&val, F &&f)
```

Update an existing element in this cache.

---

**Note:** The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

#### Parameters

- **k** – [in] The key for the value which should be updated in the cache.
- **value** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **f** – [in] A callable taking two arguments, *k* and the key found in the cache (in that order). If *f* returns *true*, then the update will continue. If *f* returns *false*, then the update will not succeed.

**Returns** This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename Entry, std::enable_if_t<std::is_convertible_v<std::decay_t<Entry>,  
entry_type>, int> = 0>
```

---

```
inline bool update(key_type const &k, Entry_ &&e)
```

Update an existing entry in this cache.

---

**Note:** The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the whole cache entry, while the other overload replaces the cached value only, leaving the cache entry properties untouched.

---

#### Parameters

- **k** – [in] The key for the entry which should be updated in the cache.
- **value** – [in] The entry which should be used as a replacement for the existing entry in the cache. Any existing entry is first removed and then this entry is added.

**Returns** This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename Func = policies::always<storage_value_type>>
inline size_type erase(Func &&ep = Func())
```

Remove stored entries from the cache for which the supplied function object returns true.

**Parameters** **ep** – [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*. Even then the entry might not be removed from the cache as its *entry::remove* function might return false.

**Returns** This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline size_type erase()
```

Remove all stored entries from the cache.

---

**Note:** All entries are considered for removal, but in the end an entry might not be removed from the cache as its *entry::remove* function might return false. This function is very useful for instance in conjunction with an entry's *entry::remove* function enforcing additional criteria like entry expiration, etc.

---

**Returns** This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline void clear()
```

Clear the cache.

Unconditionally removes all stored entries from the cache.

```
inline constexpr statistics_type const &get_statistics() const noexcept
```

Allow to access the embedded statistics instance.

**Returns** This function returns a reference to the statistics instance embedded inside this cache

```
inline statistics_type &get_statistics() noexcept
```

## Protected Functions

### hpx/cache/lru\_cache.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

namespace **cache**

```
template<typename Key, typename Entry, typename Statistics = statistics::no_statisticslru_cache
#include <hpx/cache/lru_cache.hpp> The lru_cache implements the basic functionality needed
for a local (non-distributed) LRU cache.
```

#### Template Parameters

- **Key** – The type of the keys to use to identify the entries stored in the cache
- **Entry** – The type of the items to be held in the cache.
- **Statistics** – A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type *statistics::no\_statistics* which does not collect any numbers, but provides empty stubs allowing the code to compile.

## Public Types

using **key\_type** = *Key*

using **entry\_type** = *Entry*

using **statistics\_type** = *Statistics*

using **entry\_pair** = *std::pair<key\_type, entry\_type>*

using **storage\_type** = *std::list<entry\_pair>*

```
using map_type = std::map<Key, typename storage_type::iterator>
```

```
using size_type = std::size_t
```

## Public Functions

```
inline lru_cache(size_type max_size = 0)
```

Construct an instance of a *lru\_cache*.

**Parameters** **max\_size** – [in] The maximal size this cache is allowed to reach any time.

The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry’s *get\_size* function.

```
lru_cache(lru_cache &&other) = default
```

```
inline constexpr size_type size() const noexcept
```

Return current size of the cache.

**Returns** The current size of this cache instance.

```
inline constexpr size_type capacity() const noexcept
```

Access the maximum size the cache is allowed to grow to.

---

**Note:** The unit of this value is usually determined by the unit of the return values of the entry’s function *entry::get\_size*.

---

**Returns** The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

```
inline void reserve(size_type max_size)
```

Change the maximum size this cache can grow to.

**Parameters** **max\_size** – [in] The new maximum size this cache will be allowed to grow to.

```
inline bool holds_key(key_type const &key) const
```

Check whether the cache currently holds an entry identified by the given key.

---

**Note:** This function does not call the entry’s function *entry::touch*. It just checks if the cache contains an entry corresponding to the given key.

---

**Parameters** **k** – [in] The key for the entry which should be looked up in the cache.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool get_entry(key_type const &key, key_type &realkey, entry_type &entry)
```

Get a specific entry identified by the given key.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

### Parameters

- **key** – [in] The key for the entry which should be retrieved from the cache.

- **entry** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

---

inline bool **get\_entry**(*key\_type* const &*key*, *entry\_type* const &*entry*)

Get a specific entry identified by the given key.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

#### Parameters

- **key** – [in] The key for the entry which should be retrieved from the cache.
- **entry** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns** This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

---

template<typename **Entry\_**, typename =  
*std*::enable\_if\_t<*std*::is\_convertible\_v<*std*::decay\_t<*Entry\_*>, *entry\_type*>>>  
 inline bool **insert**(*key\_type* const &*key*, *Entry\_* &&*entry*)

Insert a new entry into this cache.

---

**Note:** This function assumes that the entry is not in the cache already. Inserting an already existing entry is considered undefined behavior

#### Parameters

- **key** – [in] The key for the entry which should be added to the cache.
- **entry** – [in] The entry which should be added to the cache.

---

template<typename **Entry\_**, typename =  
*std*::enable\_if\_t<*std*::is\_convertible\_v<*std*::decay\_t<*Entry\_*>, *entry\_type*>>>  
 inline void **update**(*key\_type* const &*key*, *Entry\_* &&*entry*)

Update an existing element in this cache.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

#### Parameters

- **key** – [in] The key for the value which should be updated in the cache.
- **entry** – [in] The entry which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

---

template<typename **F**, typename **Entry\_**,  
*std*::enable\_if\_t<*std*::is\_convertible\_v<*std*::decay\_t<*Entry\_*>, *entry\_type*>, int> = 0>

```
inline bool update_if(key_type const &key, Entry_ &&entry, F &&f)
```

Update an existing element in this cache.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

#### Parameters

- **key** – [in] The key for the value which should be updated in the cache.
- **entry** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **f** – [in] A callable taking two arguments, *k* and the key found in the cache (in that order). If *f* returns true, then the update will continue. If *f* returns false, then the update will not succeed.

**Returns** This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename Func>
```

```
inline size_type erase(Func const &ep)
```

Remove stored entries from the cache for which the supplied function object returns true.

**Parameters** **ep** – [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*.

**Returns** This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline size_type erase()
```

Remove all stored entries from the cache.

**Returns** This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline size_type clear()
```

Clear the cache.

Unconditionally removes all stored entries from the cache.

```
inline constexpr statistics_type const &get_statistics() const noexcept
```

Allow to access the embedded statistics instance.

**Returns** This function returns a reference to the statistics instance embedded inside this cache

```
inline statistics_type &get_statistics() noexcept
```

## Private Types

```
using update_on_exit = typename statistics_type::update_on_exit
```

## hpx/cache/entries/entry.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

class **entry**

#include <hpx/cache/entries/entry.hpp>

### Template Parameters

- **Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and less\_than\_comparable.
- **Derived** – The (optional) type for which this type is used as a base class.

## Public Types

```
using value_type = Value
```

## Public Functions

**entry()** = default

Any cache entry has to be default constructible.

```
inline explicit entry(value_type const &val)  
    noexcept(std::is_nothrow_copy_constructible_v<value_type>)
```

Construct a new instance of a cache entry holding the given value.

```
inline explicit entry(value_type &&val) noexcept
```

Construct a new instance of a cache entry holding the given value.

```
inline constexpr bool touch() const noexcept
```

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

---

**Note:** It is possible to change the entry in a way influencing the sort criteria mandated by the UpdatePolicy. In this case the function should return *true* to indicate this to the cache, forcing to reorder the cache entries.

---

**Note:** This function is part of the CacheEntry concept

---

**Returns** This function should return *true* if the cache needs to update its internal heap.

Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

```
inline constexpr bool insert() const noexcept
```

The function *insert* is called by a cache whenever it is about to be inserted into the cache.

---

**Note:** This function is part of the CacheEntry concept

---

**Returns** This function should return *true* if the entry should be added to the cache, otherwise it should return *false*.

```
inline constexpr bool remove() const noexcept
```

The function *remove* is called by a cache holding this instance whenever it is about to be removed from the cache.

---

**Note:** This function is part of the CacheEntry concept

---

**Returns** The return value can be used to avoid removing this instance from the cache.

If the value is *true* it is ok to remove the entry, other wise it will stay in the cache.

---

inline constexpr `std::size_t get_size()` const noexcept

Return the ‘size’ of this entry. By default the size of each entry is just one (1), which is sensible if the cache has a limit (capacity) measured in number of entries.

inline `value_type &get()` noexcept

Get a reference to the stored data value.

---

**Note:** This function is part of the CacheEntry concept

---

inline constexpr `value_type const &get()` const noexcept

## Private Members

`value_type value_`

## Friends

inline friend bool `operator<(entry const &lhs, entry const &rhs)`  
`noexcept(noexcept(std::declval<value_type const&>() <`  
`std::declval<value_type const&>()))`

Forwarding operator< allowing to compare entries instead of the values.

## hpx/cache/entries/fifo\_entry.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **fifo\_entry** : public `hpx::util::cache::entries::entry<Value, fifo_entry<Value>>`

`#include <hpx/cache/entries/fifo_entry.hpp>` The `fifo_entry` type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least recently inserted entries are discarded from the cache first.

---

**Note:** The `fifo_entry` conforms to the CacheEntry concept.

---

---

**Note:** This type can be used to model a ‘last in first out’ cache policy if it is used with a `std::greater` as the caches’ `UpdatePolicy` (instead of the default `std::less`).

---

**Template Parameters** **Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and less\_than\_comparable.

## Public Functions

**fifo\_entry()** = default

Any cache entry has to be default constructible.

inline explicit **fifo\_entry**(*Value* const &val)  
    noexcept(*std*::is\_nothrow\_constructible\_v<*base\_type*, *Value*  
         const&>)

Construct a new instance of a cache entry holding the given value.

inline explicit **fifo\_entry**(*Value* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline constexpr bool **insert()**

The function *insert* is called by a cache whenever it is about to be inserted into the cache.

---

**Note:** This function is part of the CacheEntry concept

---

**Returns** This function should return *true* if the entry should be added to the cache, otherwise it should return *false*.

inline constexpr *time\_point* const &**get\_creation\_time()** const noexcept

## Private Types

using **base\_type** = *entry*<*Value*, *fifo\_entry*<*Value*>>

using **time\_point** = *std*::chrono::steady\_clock::time\_point

## Private Members

*time\_point* **insertion\_time\_**

## Friends

inline friend bool **operator<**(*fifo\_entry* const &lhs, *fifo\_entry* const &rhs)  
    noexcept(noexcept(*std*::declval<*time\_point* const&>() <  
         *std*::declval<*time\_point* const&>()))

Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been created earlier (FIFO).

**hpx/cache/entries/lfu\_entry.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **util**

        namespace **cache**

            namespace **entries**

                template<typename **Value**>

            class **lfu\_entry** : public *hpx::util::cache::entries::entry<Value, lfu\_entry<Value>>*

*#include <hpx/cache/entries/lfu\_entry.hpp>* The **lfu\_entry** type can be used to store arbitrary values in a cache. Using this type as the cache's entry type makes sure that the least frequently used entries are discarded from the cache first.

**Note:** The **lfu\_entry** conforms to the CacheEntry concept.

**Note:** This type can be used to model a ‘most frequently used’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

**Template Parameters Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and less\_than\_comparable.

## Public Functions

**lfu\_entry()** = default

Any cache entry has to be default constructible.

inline explicit **lfu\_entry**(*Value* const &*val*)  
    noexcept(*std*::is\_nothrow\_constructible\_v<*base\_type*, *Value* const&>)

Construct a new instance of a cache entry holding the given value.

inline explicit **lfu\_entry**(*Value* &&*val*) noexcept

Construct a new instance of a cache entry holding the given value.

inline bool **touch()** noexcept

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LFU entry we store the reference count tracking the number of times this entry has been requested. This which will be used to compare the age of an entry during the invocation of the *operator<()*.

**Returns** This function should return true if the cache needs to update its internal heap.

Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache’s UpdatePolicy

```
inline constexpr unsigned long const &get_access_count() const noexcept
```

## Private Types

```
using base_type = entry<Value, lfu_entry<Value>>
```

## Private Members

```
unsigned long ref_count_ = 0
```

## Friends

```
inline friend bool operator<(lfu_entry const &lhs, lfu_entry const &rhs) noexcept
    Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been accessed less frequently (LFU).
```

## hpx/cache/entries/lru\_entry.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **util**

        namespace **cache**

            namespace **entries**

                template<typename **Value**>

            class **lru\_entry** : public *hpx::util::cache::entries::entry<Value, lru\_entry<Value>>*

```
#include <hpx/cache/entries/lru_entry.hpp> The lru_entry type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least recently used entries are discarded from the cache first.
```

---

**Note:** The **lru\_entry** conforms to the CacheEntry concept.

---

---

**Note:** This type can be used to model a ‘most recently used’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

---

**Template Parameters** **Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and less\_than\_comparable.

## Public Functions

`inline lru_entry()`

Any cache entry has to be default constructible.

`inline explicit lru_entry(Value const &val)`  
`noexcept(std::is_nothrow_constructible_v<base_type, Value  
                  const&>)`

Construct a new instance of a cache entry holding the given value.

`inline explicit lru_entry(Value &&val) noexcept`

Construct a new instance of a cache entry holding the given value.

`inline bool touch()`

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LRU entry we store the time of the last access which will be used to compare the age of an entry during the invocation of the *operator<*().

**Returns** This function should return true if the cache needs to update it's internal heap.

Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

`inline constexpr time_point const &get_access_time() const noexcept`

Returns the last access time of the entry.

## Private Types

`using base_type = entry<Value, lru_entry<Value>>`

`using time_point = std::chrono::steady_clock::time_point`

## Private Members

`time_point access_time_`

## Friends

`inline friend bool operator<(lru_entry const &lhs, lru_entry const &rhs)`  
`noexcept(noexcept(std::declval<time_point const&>() <`  
`std::declval<time_point const&>()))`

Compare the 'age' of two entries. An entry is 'older' than another entry if it has been accessed less recently (LRU).

## hpx/cache/entries/size\_entry.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **util**

        namespace **cache**

            namespace **entries**

                class **size\_entry**

```
#include <hpx/cache/entries/size_entry.hpp>
```

The `size_entry` type can be used to store values in a cache which have a size associated (such as files, etc.). Using this type as the cache's entry type makes sure that the entries with the biggest size are discarded from the cache first.

---

**Note:** The `size_entry` conforms to the CacheEntry concept.

---

**Note:** This type can be used to model a ‘discard smallest first’ cache policy if it is used with a `std::greater` as the caches’ `UpdatePolicy` (instead of the default `std::less`).

---

### Template Parameters

- **Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and `less_than_comparable`.
- **Derived** – The (optional) type for which this type is used as a base class.

### Public Functions

`size_entry()` = default

Any cache entry has to be default constructible.

```
inline explicit size_entry(Value const &val, std::size_t size = 0)  
    noexcept(std::is_nothrow_constructible_v<base_type, Value,  
            Value  
            const&>)
```

Construct a new instance of a cache entry holding the given value.

```
inline explicit size_entry(Value &&val, std::size_t size = 0) noexcept
```

Construct a new instance of a cache entry holding the given value.

```
inline constexpr std::size_t get_size() const noexcept
```

Return the ‘size’ of this entry.

## Private Types

```
using derived_type = typename detail::size_derived<Value, Derived>::type  
  
using base_type = entry<Value, derived_type>
```

## Private Members

```
std::size_t size_ = 0
```

## Friends

```
inline friend constexpr friend bool operator< (size_entry const &lhs,  
size_entry const &rhs) noexcept  
Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has a bigger size.
```

## hpx/cache/statistics/local\_statistics.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **util**

        namespace **cache**

            namespace **statistics**

```
class local_statistics : public hpx::util::cache::statistics::no_statistics
```

## Public Functions

```
local_statistics() = default  
  
inline std::size_t get_and_reset(std::size_t &value, bool reset) noexcept  
  
inline constexpr std::size_t hits() const noexcept  
  
inline constexpr std::size_t misses() const noexcept  
  
inline constexpr std::size_t insertions() const noexcept  
  
inline constexpr std::size_t evictions() const noexcept  
  
inline std::size_t hits(bool reset) noexcept
```

```
inline std::size_t misses(bool reset) noexcept
inline std::size_t insertions(bool reset) noexcept
inline std::size_t evictions(bool reset) noexcept
inline void got_hit() noexcept
    The function got_hit will be called by a cache instance whenever a entry got touched.
inline void got_miss() noexcept
    The function got_miss will be called by a cache instance whenever a requested entry has not
    been found in the cache.
inline void got_insertion() noexcept
    The function got_insertion will be called by a cache instance whenever a new entry has been
    inserted.
inline void got_eviction() noexcept
    The function got_eviction will be called by a cache instance whenever an entry has been
    removed from the cache because a new inserted entry let the cache grow beyond its capacity.
inline void clear() noexcept
    Reset all statistics.
```

### Private Members

```
std::size_t hits_ = 0
std::size_t misses_ = 0
std::size_t insertions_ = 0
std::size_t evictions_ = 0
```

The function *got\_miss* will be called by a cache instance whenever a requested entry has not been found in the cache.

inline constexpr void **got\_insertion()** const noexcept

The function *got\_insertion* will be called by a cache instance whenever a new entry has been inserted.

inline constexpr void **got\_eviction()** const noexcept

The function *got\_eviction* will be called by a cache instance whenever an entry has been removed from the cache because a new inserted entry let the cache grow beyond its capacity.

inline constexpr void **clear()** const noexcept

Reset all statistics.

```
inline constexpr std::int64_t get_get_entry_count(bool) const noexcept
The function get_get_entry_count returns the number of invocations of the get_entry() API
function of the cache.

inline constexpr std::int64_t get_insert_entry_count(bool) const noexcept
The function get_insert_entry_count returns the number of invocations of the insert_entry()
API function of the cache.

inline constexpr std::int64_t get_update_entry_count(bool) const noexcept
The function get_update_entry_count returns the number of invocations of the update_entry()
API function of the cache.

inline constexpr std::int64_t get_erase_entry_count(bool) const noexcept
The function get_erase_entry_count returns the number of invocations of the erase() API
function of the cache.

inline constexpr std::int64_t get_get_entry_time(bool) const noexcept
The function get_get_entry_time returns the overall time spent executing of the get_entry()
API function of the cache.

inline constexpr std::int64_t get_insert_entry_time(bool) const noexcept
The function get_insert_entry_time returns the overall time spent executing of the in-
sert_entry() API function of the cache.

inline constexpr std::int64_t get_update_entry_time(bool) const noexcept
The function get_update_entry_time returns the overall time spent executing of the up-
date_entry() API function of the cache.

inline constexpr std::int64_t get_erase_entry_time(bool) const noexcept
The function get_erase_entry_time returns the overall time spent executing of the erase() API
function of the cache.
```

**struct update\_on\_exit**

#include <no\_statistics.hpp> Helper class to update timings and counts on function exit.

**Public Functions**

```
inline constexpr update_on_exit(no_statistics const&, method) noexcept
```

**compute\_local**

See *Public API* for a list of names and headers that are part of the public HPX API.

**hpx/compute\_local/vector.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **compute**

## Functions

```
template<typename T, typename Allocator>
void swap(vector<T, Allocator> &x, vector<T, Allocator> &y)

    Effects: x.swap(y);.

template<typename T, typename Allocator = std::allocator<T>>
class vector
```

## Public Types

```
using value_type = T
    Member types (FIXME: add reference to std.

using allocator_type = Allocator

using access_target = typename alloc_traits::access_target

using difference_type = std::ptrdiff_t

using reference = typename alloc_traits::reference

using const_reference = typename alloc_traits::const_reference

using pointer = typename alloc_traits::pointer

using const_pointer = typename alloc_traits::const_pointer

using iterator = detail::iterator<T, Allocator>

using const_iterator = detail::iterator<T const, Allocator>

using reverse_iterator = detail::reverse_iterator<T, Allocator>

using const_reverse_iterator = detail::const_reverse_iterator<T, Allocator>
```

## Public Functions

```
inline explicit vector(Allocator const &alloc = Allocator())  
  
inline vector(size_type count, T const &value, Allocator const &alloc = Allocator())  
  
inline explicit vector(size_type count, Allocator const &alloc = Allocator())  
  
template<typename InIter, typename Enable = typename  
        std::enable_if<hpx::traits::is_input_iterator<InIter>::value>::type>  
inline vector(InIter first, InIter last, Allocator const &alloc)  
  
inline vector(vector const &other)  
  
inline vector(vector const &other, Allocator const &alloc)  
  
inline vector(vector &&other)  
  
inline vector(vector &&other, Allocator const &alloc)  
  
inline vector(std::initializer_list<T> init, Allocator const &alloc)  
  
inline ~vector()  
  
inline vector &operator=(vector const &other)  
  
inline vector &operator=(vector &&other)  
  
inline allocator_type get_allocator() const noexcept  
    Returns the allocator associated with the container.  
  
inline reference operator[](size_type pos)  
  
inline const_reference operator[](size_type pos) const  
  
inline pointer data() noexcept  
    Returns pointer to the underlying array serving as element storage. The pointer is such that range  
    [data(); data() + size()] is always a valid range, even if the container is empty (data() is not deref-  
    erenceable in that case).  
  
inline const_pointer data() const noexcept  
    Returns pointer to the underlying array serving as element storage. The pointer is such that range  
    [data(); data() + size()] is always a valid range, even if the container is empty (data() is not deref-  
    erenceable in that case).  
  
inline T *device_data() const noexcept  
    Returns a raw pointer corresponding to the address of the data allocated on the device.  
  
inline std::size_t size() const noexcept  
  
inline std::size_t capacity() const noexcept  
  
inline bool empty() const noexcept  
    Returns: size() == 0.
```

---

```
inline void resize(size_type)
```

Effects: If size <= size(), equivalent to calling pop\_back() size() - size times. If size() < size, appends size - size() default-inserted elements to the sequence.

Requires: T shall be MoveInsertable and DefaultInsertable into \*this.

Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

```
inline void resize(size_type, T const&)
```

Effects: If size <= size(), equivalent to calling pop\_back() size() - size times. If size() < size, appends size - size() copies of val to the sequence.

Requires: T shall be CopyInsertable into \*this.

Remarks: If an exception is thrown there are no effects.

```
inline iterator begin() noexcept
```

```
inline iterator end() noexcept
```

```
inline const_iterator cbegin() const noexcept
```

```
inline const_iterator cend() const noexcept
```

```
inline const_iterator begin() const noexcept
```

```
inline const_iterator end() const noexcept
```

```
inline void swap(vector &other)
```

Effects: Exchanges the contents and capacity() of \*this with that of x.

Complexity: Constant time.

```
inline void clear() noexcept
```

Effects: Erases all elements in the range [begin(),end()). Destroys all elements in a. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.

Post: a.empty() returns true.

Complexity: Linear.

namespace **hpx**

    namespace **threads**

### Enums

enum class **thread\_schedule\_state** : *std::int8\_t*

The *thread\_schedule\_state* enumerator encodes the current state of a *thread* instance

*Values:*

enumerator **unknown**

enumerator **active**

    thread is currently active (running, has resources)

enumerator **pending**

    thread is pending (ready to run, but no hardware resource available)

enumerator **suspended**

    thread has been suspended (waiting for synchronization event, but still known and under control of the thread-manager)

enumerator **depleted**

    thread has been depleted (deeply suspended, it is not known to the thread-manager)

enumerator **terminated**

    thread has been stopped and may be garbage collected

**enumerator `staged`**

this is not a real thread state, but allows to reference staged task descriptions, which eventually will be converted into thread objects

**enumerator `pending_do_not_schedule`****enumerator `pending_boost`****enum class `thread_priority` : `std::int8_t`**

This enumeration lists all possible thread-priorities for HPX threads.

*Values:*

**enumerator `unknown`****enumerator `default_`**

Will assign the priority of the task to the default (normal) priority.

**enumerator `low`**

Task goes onto a special low priority queue and will not be executed until all high/normal priority tasks are done, even if they are added after the low priority task.

**enumerator `normal`**

Task will be executed when it is taken from the normal priority queue, this is usually a first-in-first-out ordering of tasks (depending on scheduler choice). This is the default priority.

**enumerator `high_recursive`**

The task is a high priority task and any child tasks spawned by this task will be made high priority as well - unless they are specifically flagged as non default priority.

**enumerator `boost`**

Same as `thread_priority_high` except that the thread will fall back to `thread_priority_normal` if resumed after being suspended.

**enumerator `high`**

Task goes onto a special high priority queue and will be executed before normal/low priority tasks are taken (some schedulers modify the behavior slightly and the documentation for those should be consulted).

**enumerator `bound`**

Task goes onto a special high priority queue and will never be stolen by another thread after initial assignment. This should be used for thread placement tasks such as OpenMP type for loops.

**enum class `thread_restart_state` : `std::int8_t`**

The `thread_restart_state` enumerator encodes the reason why a thread is being restarted

*Values:*

enumerator **unknown**

enumerator **signaled**

The thread has been signaled.

enumerator **timeout**

The thread has been reactivated after a timeout

enumerator **terminate**

The thread needs to be terminated.

enumerator **abort**

The thread needs to be aborted.

enum class **thread\_stacksize** : *std*::int8\_t

A *thread\_stacksize* references any of the possible stack-sizes for HPX threads.

*Values:*

enumerator **unknown**

enumerator **small\_**

use small stack size (the underscore is to work around small being defined to char on Windows)

enumerator **medium**

use medium sized stack size

enumerator **large**

use large stack size

enumerator **huge**

use very large stack size

enumerator **nostack**

this thread does not suspend (does not need a stack)

enumerator **current**

use size of current thread's stack

enumerator **default\_**

use default stack size

enumerator **minimal**

use minimally stack size

enumerator **maximal**

use maximally stack size

enum class **thread\_schedule\_hint\_mode** : *std*::int8\_t

The type of hint given when creating new tasks.

*Values:*

enumerator **none**

A hint that leaves the choice of scheduling entirely up to the scheduler.

enumerator **thread**

A hint that tells the scheduler to prefer scheduling a task on the local thread number associated with this hint. Local thread numbers are indexed from zero. It is up to the scheduler to decide how to interpret thread numbers that are larger than the number of threads available to the scheduler. Typically thread numbers will wrap around when too large.

enumerator **numa**

A hint that tells the scheduler to prefer scheduling a task on the NUMA domain associated with this hint. NUMA domains are indexed from zero. It is up to the scheduler to decide how to interpret NUMA domain indices that are larger than the number of available NUMA domains to the scheduler. Typically indices will wrap around when too large.

## Functions

*std*::ostream &**operator<<**(*std*::ostream &os, *thread\_schedule\_state* const t)

char const \***get\_thread\_state\_name**(*thread\_schedule\_state* state)

Returns the name of the given state.

Get the readable string representing the name of the given thread\_state constant.

**Parameters** **state** – this represents the thread state.

*std*::ostream &**operator<<**(*std*::ostream &os, *thread\_priority* const t)

char const \***get\_thread\_priority\_name**(*thread\_priority* priority)

Return the thread priority name.

Get the readable string representing the name of the given thread\_priority constant.

**Parameters** **this** – represents the thread priority.

*std*::ostream &**operator<<**(*std*::ostream &os, *thread\_restart\_state* const t)

char const \***get\_thread\_state\_ex\_name**(*thread\_restart\_state* state)

Get the readable string representing the name of the given thread\_restart\_state constant.

char const \***get\_thread\_state\_name**(*thread\_state* state)

Get the readable string representing the name of the given thread\_state constant.

*std*::ostream &**operator<<**(*std*::ostream &os, *thread\_stacksize* const t)

---

```
char const *get_stack_size_enum_name(thread_stacksize size)
```

Returns the stack size name.

Get the readable string representing the given stack size constant.

**Parameters** **size** – this represents the stack size

```
struct thread_schedule_hint
```

```
#include <thread_enums.hpp> A hint given to a scheduler to guide where a task should be scheduled.
```

A scheduler is free to ignore the hint, or modify the hint to suit the resources available to the scheduler.

## Public Functions

```
inline constexpr thread_schedule_hint() noexcept
```

Construct a default hint with mode `thread_schedule_hint_mode::none`.

```
inline explicit constexpr thread_schedule_hint(std::int16_t thread_hint) noexcept
```

Construct a hint with mode `thread_schedule_hint_mode::thread` and the given hint as the local thread number.

```
inline constexpr thread_schedule_hint(thread_schedule_hint_mode mode, std::int16_t hint)  
noexcept
```

Construct a hint with the given mode and hint. The numerical hint is unused when the mode is `thread_schedule_hint_mode::none`.

## Public Members

*std*::int16\_t **hint**

The hint associated with the mode. The interpretation of this hint depends on the given mode.

*thread\_schedule\_hint\_mode* **mode**

The mode of the scheduling hint.

## hpx/coroutines/thread\_id\_type.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Enums

enum **error**

Possible error conditions.

This enumeration lists all possible error conditions which can be reported from any of the API functions.

*Values:*

enumerator **success**

The operation was successful.

**enumerator `no_success`**

The operation did failed, but not in an unexpected manner.

**enumerator `not_implemented`**

The operation is not implemented.

**enumerator `out_of_memory`**

The operation caused an out of memory condition.

**enumerator `bad_action_code`****enumerator `bad_component_type`**

The specified component type is not known or otherwise invalid.

**enumerator `network_error`**

A generic network error occurred.

**enumerator `version_too_new`**

The version of the network representation for this object is too new.

**enumerator `version_too_old`**

The version of the network representation for this object is too old.

**enumerator `version_unknown`**

The version of the network representation for this object is unknown.

**enumerator `unknown_component_address`****enumerator `duplicate_component_address`**

The given global id has already been registered.

**enumerator `invalid_status`**

The operation was executed in an invalid status.

**enumerator `bad_parameter`**

One of the supplied parameters is invalid.

**enumerator `internal_server_error`****enumerator `service_unavailable`****enumerator `bad_request`****enumerator `repeated_request`**

enumerator **lock\_error**

enumerator **duplicate\_console**

There is more than one console locality.

enumerator **no\_registered\_console**

There is no registered console locality available.

enumerator **startup\_timed\_out**

enumerator **uninitialized\_value**

enumerator **bad\_response\_type**

enumerator **deadlock**

enumerator **assertion\_failure**

enumerator **null\_thread\_id**

Attempt to invoke a API function from a non-HPX thread.

enumerator **invalid\_data**

enumerator **yield\_aborted**

The yield operation was aborted.

enumerator **dynamic\_link\_failure**

enumerator **commandline\_option\_error**

One of the options given on the command line is erroneous.

enumerator **serialization\_error**

There was an error during serialization of this object.

enumerator **unhandled\_exception**

An unhandled exception has been caught.

enumerator **kernel\_error**

The OS kernel reported an error.

enumerator **broken\_task**

The task associated with this future object is not available anymore.

**enumerator `task_moved`**

The task associated with this future object has been moved.

**enumerator `task_already_started`**

The task associated with this future object has already been started.

**enumerator `future_already_retrieved`**

The future object has already been retrieved.

**enumerator `promise_already_satisfied`**

The value for this future object has already been set.

**enumerator `future_does_not_support_cancellation`**

The future object does not support cancellation.

**enumerator `future_can_not_be_cancelled`**

The future can't be canceled at this time.

**enumerator `no_state`**

The future object has no valid shared state.

**enumerator `broken.promise`**

The promise has been deleted.

migration failed because of global race, retry

## hpx/errors/error\_code.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Unnamed Group

inline `error_code make_error_code(error e, throwmode mode = throwmode::plain)`

Returns a new `error_code` constructed from the given parameters.

inline `error_code make_error_code(error e, char const *func, char const *file, long line, throwmode mode = throwmode::plain)`

inline `error_code make_error_code(error e, char const *msg, throwmode mode = throwmode::plain)`

Returns error\_code(e, msg, mode).

inline `error_code make_error_code(error e, char const *msg, char const *func, char const *file, long line, throwmode mode = throwmode::plain)`

inline `error_code make_error_code(error e, std::string const &msg, throwmode mode = throwmode::plain)`

Returns error\_code(e, msg, mode).

inline `error_code make_error_code(error e, std::string const &msg, char const *func, char const *file, long line, throwmode mode = throwmode::plain)`

inline `error_code make_error_code(std::exception_ptr const &e)`

## Functions

`std::error_category const &get_hpx_category()`

Returns generic HPX error category used for new errors.

`std::error_category const &get_hpx_rethrow_category()`

Returns generic HPX error category used for errors re-thrown after the exception has been de-serialized.

inline `error_code make_success_code(throwmode mode = throwmode::plain)`

Returns `error_code`(hpx::success, “success”, mode).

class `error_code` : public `error_code`

`#include <error_code.hpp>` A `hpx::error_code` represents an arbitrary error condition.

The class `hpx::error_code` describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

---

**Note:** Class `hpx::error_code` is an adjunct to error reporting by exception

---

## Public Functions

inline explicit `error_code(throwmode mode = throwmode::plain)`

Construct an object of type `error_code`.

**Parameters** `mode` – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** nothing –

`explicit error_code(error e, throwmode mode = throwmode::plain)`

Construct an object of type `error_code`.

**Parameters**

- `e` – The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `mode` – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** nothing –

`error_code(error e, char const *func, char const *file, long line, throwmode mode = throwmode::plain)`

Construct an object of type `error_code`.

**Parameters**

- `e` – The parameter `e` holds the hpx::error code the new exception should encapsulate.
- `func` – The name of the function where the error was raised.
- `file` – The file name of the code where the error was raised.
- `line` – The line number of the code line where the error was raised.
- `mode` – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** nothing –

`error_code(error e, char const *msg, throwmode mode = throwmode::plain)`

Construct an object of type `error_code`.

**Parameters**

- `e` – The parameter `e` holds the hpx::error code the new exception should encapsulate.

- **msg** – The parameter `msg` holds the error message the new exception should encapsulate.
- **mode** – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** `std::bad_alloc` – (if allocation of a copy of the passed string fails).

**error\_code**(`error e`, `char const *msg`, `char const *func`, `char const *file`, `long line`, `throwmode mode = throwmode::plain`)

Construct an object of type `error_code`.

**Parameters**

- **e** – The parameter `e` holds the `hpx::error` code the new exception should encapsulate.
- **msg** – The parameter `msg` holds the error message the new exception should encapsulate.
- **func** – The name of the function where the error was raised.
- **file** – The file name of the code where the error was raised.
- **line** – The line number of the code line where the error was raised.
- **mode** – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** `std::bad_alloc` – (if allocation of a copy of the passed string fails).

**error\_code**(`error e`, `std::string const &msg`, `throwmode mode = throwmode::plain`)

Construct an object of type `error_code`.

**Parameters**

- **e** – The parameter `e` holds the `hpx::error` code the new exception should encapsulate.
- **msg** – The parameter `msg` holds the error message the new exception should encapsulate.
- **mode** – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** `std::bad_alloc` – (if allocation of a copy of the passed string fails).

**error\_code**(`error e`, `std::string const &msg`, `char const *func`, `char const *file`, `long line`, `throwmode mode = throwmode::plain`)

Construct an object of type `error_code`.

**Parameters**

- **e** – The parameter `e` holds the `hpx::error` code the new exception should encapsulate.
- **msg** – The parameter `msg` holds the error message the new exception should encapsulate.
- **func** – The name of the function where the error was raised.
- **file** – The file name of the code where the error was raised.
- **line** – The line number of the code line where the error was raised.
- **mode** – The parameter `mode` specifies whether the constructed `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**Throws** `std::bad_alloc` – (if allocation of a copy of the passed string fails).

`std::string get_message() const`

Return a reference to the error message stored in the `hpx::error_code`.

**Throws** `nothing` –

`inline void clear()`

Clear this `error_code` object. The postconditions of invoking this method are.

- `value() == hpx::success` and `category() == hpx::get_hpx_category()`

**error\_code**(`error_code const &rhs`)

Copy constructor for `error_code`

---

**Note:** This function maintains the error category of the left hand side if the right hand side is a success code.

---

`error_code &operator=(error_code const &rhs)`

Assignment operator for `error_code`

---

**Note:** This function maintains the error category of the left hand side if the right hand side is a success code.

---

## Private Functions

`error_code(int err, hpx::exception const &e)`

## hpx/errors/exception.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

## Typedefs

`using custom_exception_info_handler_type = std::function<hpx::exception_info(std::string const&, std::string const&, long, std::string const&)>`

`using pre_exception_handler_type = std::function<void()>`

## Functions

`void set_custom_exception_info_handler(custom_exception_info_handler_type f)`

`void set_pre_exception_handler(pre_exception_handler_type f)`

`std::string get_error_what(exception_info const &xi)`

Return the error message of the thrown exception.

The function `hpx::get_error_what` can be used to extract the diagnostic information element representing the error message as stored in the given exception instance.

### See also:

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_thread_description()`,  
`hpx::get_error()`      `hpx::get_error_backtrace()`,      `hpx::get_error_env()`,      `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The error message stored in the exception. If the exception instance does not hold this information, the function will return an empty string.

`error get_error(hpx::exception const &e)`

Return the error code value of the exception thrown.

The function `hpx::get_error` can be used to extract the diagnostic information element representing the error value code as stored in the given exception instance.

### See also:

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,

`hpx::get_error_backtrace()`,      `hpx::get_error_env()`,      `hpx::get_error_what()`,      `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters** `e` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception`, `hpx::error_code`, or `std::exception_ptr`.

**Throws** nothing –

**Returns** The error value code of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return `hpx::naming::invalid_locality_id`.

`error get_error(hpx::error_code const &e)`

`std::string get_error_function_name(hpx::exception_info const &xi)`

Return the function name from which the exception was thrown.

The function `hpx::get_error_function_name` can be used to extract the diagnostic information element representing the name of the function as stored in the given exception instance.

**See also:**

<code>hpx::diagnostic_information()</code> ,	<code>hpx::get_error_host_name()</code> ,	<code>hpx::get_error_process_id()</code> ,

<code>hpx::get_error_state()</code>		<code>hpx::get_error_config()</code> ,

**Parameters xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The name of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_file_name(hpx::exception_info const &xi)`

Return the (source code) file name of the function from which the exception was thrown.

The function `hpx::get_error_file_name` can be used to extract the diagnostic information element representing the name of the source file as stored in the given exception instance.

**See also:**

<code>hpx::diagnostic_information()</code> ,	<code>hpx::get_error_host_name()</code> ,	<code>hpx::get_error_process_id()</code> ,
<code>hpx::get_error_function_name()</code> ,	<code>hpx::get_error_line_number()</code> ,	<code>hpx::get_error_os_thread()</code> ,

<code>hpx::get_error_state()</code>		<code>hpx::get_error_config()</code> ,

**Parameters xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The name of the source file of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`long get_error_line_number(hpx::exception_info const &xi)`

Return the line number in the (source code) file of the function from which the exception was thrown.

The function `hpx::get_error_line_number` can be used to extract the diagnostic information element representing the line number as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_os_thread()`,  
`hpx::get_error_thread_id()`,      `hpx::get_error_thread_description()`,      `hpx::get_error()`,  
`hpx::get_error_backtrace()`,    `hpx::get_error_env()`,    `hpx::get_error_what()`,    `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** nothing –

**Returns** The line number of the place where the exception was thrown. If the exception instance does not hold this information, the function will return -1.

class **exception** : public system\_error

#include <exception.hpp> A `hpx::exception` is the main exception type used by HPX to report errors.

The `hpx::exception` type is the main exception type used by HPX to report errors. Any exceptions thrown by functions in the HPX library are either of this type or of a type derived from it. This implies that it is always safe to use this type only in catch statements guarding HPX library calls.

Subclassed by `hpx::exception_list`

## Public Functions

explicit **exception**(`error` e = success)

Construct a `hpx::exception` from a `hpx::error`.

**Parameters** `e` – The parameter `e` holds the `hpx::error` code the new exception should encapsulate.

explicit **exception**(`std::system_error` const &`e`)

Construct a `hpx::exception` from a `boost::system_error`.

explicit **exception**(`std::error_code` const &`e`)

Construct a `hpx::exception` from a `boost::system::error_code` (this is new for Boost V1.69). This constructor is required to compensate for the changes introduced as a resolution to LWG3162 (<https://cplusplus.github.io/LWG/issue3162>).

**exception**(`error` e, char const \*msg, `throwmode` mode = `throwmode::plain`)

Construct a `hpx::exception` from a `hpx::error` and an error message.

**Parameters**

- `e` – The parameter `e` holds the `hpx::error` code the new exception should encapsulate.
- `msg` – The parameter `msg` holds the error message the new exception should encapsulate.
- `mode` – The parameter `mode` specifies whether the returned `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

**exception**(`error` e, `std::string` const &`msg`, `throwmode` mode = `throwmode::plain`)

Construct a `hpx::exception` from a `hpx::error` and an error message.

**Parameters**

- `e` – The parameter `e` holds the `hpx::error` code the new exception should encapsulate.
- `msg` – The parameter `msg` holds the error message the new exception should encapsulate.

- **mode** – The parameter mode specifies whether the returned `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

`~exception() noexcept`

Destruct a `hpx::exception`

**Throws** nothing –

`error get_error() const noexcept`

The function `get_error()` returns the `hpx::error` code stored in the referenced instance of a `hpx::exception`. It returns the `hpx::error` code this exception instance was constructed from.

**Throws** nothing –

`error_code get_error_code(throwmode mode = throwmode::plain) const noexcept`

The function `get_error_code()` returns a `hpx::error_code` which represents the same error condition as this `hpx::exception` instance.

**Parameters** `mode` – The parameter mode specifies whether the returned `hpx::error_code` belongs to the error category `hpx_category` (if mode is `throwmode::plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

struct `thread_interrupted` : public `exception`

#include <exception.hpp> A `hpx::thread_interrupted` is the exception type used by HPX to interrupt a running HPX thread.

The `hpx::thread_interrupted` type is the exception type used by HPX to interrupt a running thread. A running thread can be interrupted by invoking the `interrupt()` member function of the corresponding `hpx::thread` object. When the interrupted thread next executes one of the specified interruption points (or if it is currently blocked whilst executing one) with interruption enabled, then a `hpx::thread_interrupted` exception will be thrown in the interrupted thread. If not caught, this will cause the execution of the interrupted thread to terminate. As with any other exception, the stack will be unwound, and destructors for objects of automatic storage duration will be executed.

If a thread wishes to avoid being interrupted, it can create an instance of `hpx::this_thread::disable_interruption`. Objects of this class disable interruption for the thread that created them on construction, and restore the interruption state to whatever it was before on destruction.

```
void f()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::disable_interruption di2;
            // interruption still disabled
        } // di2 destroyed, interruption state restored
        // interruption still disabled
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

The effects of an instance of `hpx::this_thread::disable_interruption` can be temporarily reversed by constructing an instance of `hpx::this_thread::restore_interruption`, passing in the

*hpx::this\_thread::disable\_interruption* object in question. This will restore the interruption state to what it was when the *hpx::this\_thread::disable\_interruption* object was constructed, and then disable interruption again when the *hpx::this\_thread::restore\_interruption* object is destroyed.

```
void g()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::restore_interruption ri(di);
            // interruption now enabled
        } // ri destroyed, interruption disable again
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

At any point, the interruption state for the current thread can be queried by calling *hpx::this\_thread::interruption\_enabled()*.

## hpx/errors/exception\_fwd.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

**HPX\_THROWMODE\_UNSCOPED\_ENUM\_DEPRECATED\_MSG**

namespace **hpx**

### Enums

enum class **throwmode** : *std::uint8\_t*  
Encode error category for new *error\_code*.  
*Values:*

enumerator **plain**

enumerator **rethrow**

enumerator **lightweight**

## Functions

```
inline constexpr bool operator&(throwmode lhs, throwmode rhs) noexcept
```

## Variables

```
constexpr throwmode plain = throwmode::plain
```

```
constexpr throwmode rethrow = throwmode::rethrow
```

```
constexpr throwmode lightweight = throwmode::lightweight
```

```
constexpr throwmode lightweight_rethrow = throwmode::lightweight_rethrow
```

### *error\_code* throws

Predefined *error\_code* object used as “throw on error” tag.

The predefined *hpx::error\_code* object *hpx::throws* is supplied for use as a “throw on error” tag.

Functions that specify an argument in the form ‘*error\_code*& ec=throws’ (with appropriate namespace qualifiers), have the following error handling semantics:

If &ec != &throws and an error occurred: ec.value() returns the implementation specific error number for the particular error that occurred and ec.category() returns the error\_category for ec.value().

If &ec != &throws and an error did not occur, ec.clear().

If an error occurs and &ec == &throws, the function throws an exception of type *hpx::exception* or of a type derived from it. The exception’s *get\_errorcode()* member function returns a reference to an *hpx::error\_code* object with the behavior as specified above.

## hpx/errors/exception\_list.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

```
class exception_list : public hpx::exception
```

```
#include <exception_list.hpp> The class exception_list is a container of exception_ptr objects parallel algorithms may use to communicate uncaught exceptions encountered during parallel execution to the caller of the algorithm
```

The type *exception\_list*::const\_iterator fulfills the requirements of a forward iterator.

## Public Types

```
using iterator = exception_list_type::const_iterator  
bidirectional iterator
```

## Public Functions

```
inline std::size_t size() const noexcept
```

The number of exception\_ptr objects contained within the *exception\_list*.

---

**Note:** Complexity: Constant time.

---

```
inline exception_list_type::const_iterator begin() const noexcept
```

An iterator referring to the first exception\_ptr object contained within the *exception\_list*.

```
inline exception_list_type::const_iterator end() const noexcept
```

An iterator which is the past-the-end value for the *exception\_list*.

## hpx/errors/throw\_exception.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

### Defines

**HPX\_THROW\_EXCEPTION**(errcode, f, ...)

Throw a *hpx::exception* initialized from the given parameters.

The macro *HPX\_THROW\_EXCEPTION* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter *errcode* holds the hpx::error code the new exception should encapsulate. The parameter *f* is expected to hold the name of the function exception is thrown from and the parameter *msg* holds the error message the new exception should encapsulate.

```
void raise_exception()  
{  
    // Throw a hpx::exception initialized from the given parameters.  
    // Additionally associate with this exception some detailed  
    // diagnostic information about the throw-site.  
    HPX_THROW_EXCEPTION(hpx::no_success, "raise_exception", "simulated error");  
}
```

**Example:**

**HPX\_THROWS\_IF**(ec, errcode, f, ...)

Either throw a `hpx::exception` or initialize `hpx::error_code` from the given parameters.

The macro `HPX_THROWS_IF` can be used to either throw a `hpx::exception` or to initialize a `hpx::error_code` from the given parameters. If `&ec == &hpx::throws`, the semantics of this macro are equivalent to `HPX_THROW_EXCEPTION`. If `&ec != &hpx::throws`, the `hpx::error_code` instance `ec` is initialized instead.

The parameter `errcode` holds the `hpx::error` code from which the new exception should be initialized. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

namespace **hpx**

**execution**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

**`hpx/execution/executors/adaptive_static_chunk_size.hpp`**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

namespace **hpx**

namespace **execution**

**struct `adaptive_static_chunk_size`**

`#include <adaptive_static_chunk_size.hpp>` Loop iterations are divided into pieces of size `chunk_size` and then assigned to threads. If `chunk_size` is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

---

**Note:** This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.

---

**Public Functions**

inline constexpr **`adaptive_static_chunk_size()`** noexcept

Construct a `adaptive_static_chunk_size` executor parameters object

---

**Note:** By default the number of loop iterations is determined from the number of available cores and the overall number of loop iterations to schedule.

---

inline explicit constexpr **`adaptive_static_chunk_size(std::size_t chunk_size)`** noexcept

Construct a `adaptive_static_chunk_size` executor parameters object

**Parameters** `chunk_size` – [in] The optional chunk size to use as the number of loop iterations to run on a single thread.

namespace **parallel**

namespace **execution**

## hpx/execution/executors/auto\_chunk\_size.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

struct **auto\_chunk\_size**

```
#include <auto_chunk_size.hpp>
```

Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

### Public Functions

inline constexpr **auto\_chunk\_size**(*std*::uint64\_t num\_iters\_for\_timing = 0) noexcept

Construct an `auto_chunk_size` executor parameters object

---

**Note:** Default constructed `auto_chunk_size` executor parameter types will use 80 microseconds as the minimal time for which any of the scheduled chunks should run.

---

inline explicit **auto\_chunk\_size**(*hpx*::chrono::steady\_duration const &*rel\_time*, *std*::uint64\_t num\_iters\_for\_timing = 0) noexcept

Construct an `auto_chunk_size` executor parameters object

**Parameters** *rel\_time* – [in] The time duration to use as the minimum to decide how many loop iterations should be combined.

namespace **parallel**

namespace **execution**

## hpx/execution/executors/dynamic\_chunk\_size.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

```
struct dynamic_chunk_size
```

```
#include <dynamic_chunk_size.hpp> Loop iterations are divided into pieces of size chunk_size and then dynamically scheduled among the threads; when a thread finishes one chunk, it is dynamically assigned another. If chunk_size is not specified, the default chunk size is 1.
```

---

**Note:** This executor parameters type is equivalent to OpenMP's DYNAMIC scheduling directive.

---

## Public Functions

```
inline explicit constexpr dynamic_chunk_size(std::size_t chunk_size = 1) noexcept
```

```
Construct a dynamic_chunk_size executor parameters object
```

```
Parameters chunk_size – [in] The optional chunk size to use as the number of loop iterations to schedule together. The default chunk size is 1.
```

```
namespace parallel
```

```
namespace execution
```

## hpx/execution/executors/execution.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
namespace parallel
```

```
namespace execution
```

## hpx/execution/executors/execution\_information.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
namespace parallel
```

```
namespace execution
```

## Variables

`hpx::parallel::execution::has_pending_closures_t has_pending_closures`

`hpx::parallel::execution::get_pu_mask_t get_pu_mask`

`hpx::parallel::execution::set_scheduler_mode_t set_scheduler_mode`

```
struct get_pu_mask_t : public hpx::functional::detail::tag_fallback<get_pu_mask_t>
    #include <execution_information.hpp> Retrieve the bitmask describing the processing units the
    given thread is allowed to run on
    All threads::executors invoke sched.get_pu_mask().
```

---

**Note:** If the executor does not support this operation, this call will always invoke `hpx::threads::get_pu_mask()`

---

**Param exec** [in] The executor object to use for querying the number of pending tasks.

**Param topo** [in] The topology object to use to extract the requested information.

**Param tstream\_num** [in] The sequence number of the thread to retrieve information for.

## Private Functions

```
template<typename Executor>
inline decltype(auto) friend tagFallback_invoke(get_pu_mask_t, Executor&&,  

                                                 threads::topology &topo, std::size_t  

                                                 thread_num)
```

```
template<typename Executor>
inline decltype(auto) friend tag_invoke(get_pu_mask_t, Executor &&exec, threads::topology  

                                         &topo, std::size_t thread_num)
```

```
struct has_pending_closures_t : public
hpx::functional::detail::tag_fallback<has_pending_closures_t>
    #include <execution_information.hpp> Retrieve whether this executor has operations pending or
    not.
```

---

**Note:** If the executor does not expose this information, this call will always return `false`

---

**Param exec** [in] The executor object to use to extract the requested information for.

## Private Functions

```
template<typename Executor>
inline decltype(auto) friend tagFallback_invoke(has_pending_closures_t, Executor&&)

template<typename Executor>
inline decltype(auto) friend tag_invoke(has_pending_closures_t, Executor &&exec)

struct set_scheduler_mode_t : public
    hpx::functional::detail::tag_fallback<set_scheduler_mode_t>

#include <execution_information.hpp> Set various modes of operation on the scheduler underneath the given executor.
```

---

**Note:** This calls exec.set\_scheduler\_mode(mode) if it exists; otherwise it does nothing.

---

**Param exec** [in] The executor object to use.

**Param mode** [in] The new mode for the scheduler to pick up

## Friends

```
template<typename Executor, typename Mode>
inline friend void tagFallback_invoke(set_scheduler_mode_t, Executor&&, Mode const&)

template<typename Executor, typename Mode>
inline friend void tag_invoke(set_scheduler_mode_t, Executor &&exec, Mode const &mode)
```

## hpx/execution/executors/execution\_parameters.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parallel**

namespace **execution**

## Functions

```
template<typename ...Params>
constexpr executor_parameters_join<Params...>::type join_executor_parameters(Params&&...
    params)

template<typename Param>
constexpr Param &&join_executor_parameters(Param &&param) noexcept

template<typename ...Params>
struct executor_parameters_join
```

## Public Types

```
using type = detail::executor_parameters<std::decay_t<Params>...>
template<typename Param>
struct executor_parameters_join<Param>
```

## Public Types

```
using type = Param
```

### `hpx/execution/executors/execution_parameters_fwd.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **parallel**

        namespace **execution**

## Variables

*hpx::parallel::execution::get\_chunk\_size\_t* **get\_chunk\_size**

*hpx::parallel::execution::maximal\_number\_of\_chunks\_t* **maximal\_number\_of\_chunks**

*hpx::parallel::execution::reset\_thread\_distribution\_t* **reset\_thread\_distribution**

*hpx::parallel::execution::processing\_units\_count\_t* **processing\_units\_count**

*hpx::parallel::execution::with\_processing\_units\_count\_t* **with\_processing\_units\_count**

*hpx::parallel::execution::mark\_begin\_execution\_t* **mark\_begin\_execution**

*hpx::parallel::execution::mark\_end\_of\_scheduling\_t* **mark\_end\_of\_scheduling**

*hpx::parallel::execution::mark\_end\_execution\_t* **mark\_end\_execution**

---

```
struct get_chunk_size_t : public hpx::functional::detail::tag_fallback<get_chunk_size_t>
#include <execution_parameters_fwd.hpp> Return the number of invocations of the given function f which should be combined into a single task
```

---

**Note:** The parameter *f* is expected to be a nullary function returning a `std::size_t` representing the number of iteration the function has already executed (i.e. which don't have to be scheduled anymore).

**Param params** [in] The executor parameters object to use for determining the chunk size for the given number of tasks *num\_tasks*.  
**Param exec** [in] The executor object which will be used for scheduling of the loop iterations.  
**Param f** [in] The function which will be optionally scheduled using the given executor.  
**Param cores** [in] The number of cores the number of chunks should be determined for.  
**Param num\_tasks** [in] The number of tasks the chunk size should be determined for

### Private Functions

```
template<typename Parameters, typename Executor, typename F>
inline decltype(auto) friend tag_fallback_invoke(get_chunk_size_t, Parameters &&params,
                                                Executor &&exec, F &&f, std::size_t
                                                cores, std::size_t num_tasks)
```

```
struct mark_begin_execution_t : public
hpx::functional::detail::tag_fallback<mark_begin_execution_t>
#include <execution_parameters_fwd.hpp> Mark the begin of a parallel algorithm execution
```

---

**Note:** This calls *params.mark\_begin\_execution(exec)* if it exists; otherwise it does nothing.

**Param params** [in] The executor parameters object to use as a fallback if the executor does not expose

### Private Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) friend tag_fallback_invoke(mark_begin_execution_t, Parameters
                                                &&params, Executor &&exec)
```

```
struct mark_end_execution_t : public
hpx::functional::detail::tag_fallback<mark_end_execution_t>
#include <execution_parameters_fwd.hpp> Mark the end of a parallel algorithm execution
```

---

**Note:** This calls *params.mark\_end\_execution(exec)* if it exists; otherwise it does nothing.

**Param params** [in] The executor parameters object to use as a fallback if the executor does not expose

## Private Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) friend tagFallback_invoke(mark_end_execution_t, Parameters
&&params, Executor &&exec)

struct mark_end_of_scheduling_t : public
hpx::functional::detail::tagFallback<mark_end_of_scheduling_t>
#include <execution_parameters_fwd.hpp> Mark the end of scheduling tasks during parallel algorithm execution
```

---

**Note:** This calls params.mark\_begin\_execution(exec) if it exists; otherwise it does nothing.

---

**Param params** [in] The executor parameters object to use as a fallback if the executor does not expose

## Private Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) friend tagFallback_invoke(mark_end_of_scheduling_t, Parameters
&&params, Executor &&exec)
```

```
struct maximal_number_of_chunks_t : public
hpx::functional::detail::tagFallback<maximal_number_of_chunks_t>
#include <execution_parameters_fwd.hpp> Return the largest reasonable number of chunks to create for a single algorithm invocation.
```

**Param params** [in] The executor parameters object to use for determining the number of chunks for the given number of *cores*.

**Param exec** [in] The executor object which will be used for scheduling of the loop iterations.

**Param cores** [in] The number of cores the number of chunks should be determined for.

**Param num\_tasks** [in] The number of tasks the chunk size should be determined for

## Private Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) friend tagFallback_invoke(maximal_number_of_chunks_t,
Parameters &&params, Executor
&&exec, std::size_t cores, std::size_t
num_tasks)
```

```
struct processing_units_count_t : public
hpx::functional::detail::tagFallback<processing_units_count_t>
#include <execution_parameters_fwd.hpp> Retrieve the number of (kernel-)threads used by the associated executor.
```

---

**Note:** This calls params.processing\_units\_count(Executor&&) if it exists; otherwise it forwards the request to the executor parameters object.

---

---

**Param params** [in] The executor parameters object to use as a fallback if the executor does not expose

### Private Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) friend tag_fallback_invoke(processing_units_count_t, Parameters
&&params, Executor &&exec)
```

```
struct reset_thread_distribution_t : public
hpx::functional::detail::tag_fallback<reset_thread_distribution_t>
#include <execution_parameters_fwd.hpp> Reset the internal round robin thread distribution
scheme for the given executor.
```

---

**Note:** This calls params.reset\_thread\_distribution(exec) if it exists; otherwise it does nothing.

---

**Param params** [in] The executor parameters object to use for resetting the thread distribution scheme.

**Param exec** [in] The executor object to use.

### Private Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) friend tag_fallback_invoke(reset_thread_distribution_t, Parameters
&&params, Executor &&exec)
```

```
struct with_processing_units_count_t : public
hpx::functional::detail::tag_fallback<with_processing_units_count_t>
#include <execution_parameters_fwd.hpp> Generate a policy that supports setting the number of
cores for execution.
```

## **hpx/execution/executors/guided\_chunk\_size.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

struct **guided\_chunk\_size**

```
#include <guided_chunk_size.hpp> Iterations are dynamically assigned to threads in blocks as threads
request them until no blocks remain to be assigned. Similar to dynamic_chunk_size except that the
block size decreases each time a number of loop iterations is given to a thread. The size of the initial
block is proportional to number_of_iterations / number_of_cores. Subsequent blocks are proportional
to number_of_iterations_remaining / number_of_cores. The optional chunk size parameter defines the
minimum block size. The default chunk size is 1.
```

---

**Note:** This executor parameters type is equivalent to OpenMP's GUIDED scheduling directive.

---

## Public Functions

inline explicit constexpr **guided\_chunk\_size**(*std*::size\_t min\_chunk\_size = 1) noexcept  
Construct a `guided_chunk_size` executor parameters object  
**Parameters** `min_chunk_size` – [in] The optional minimal chunk size to use as the minimal number of loop iterations to schedule together. The default minimal chunk size is 1.

namespace **parallel**

namespace **execution**

## **hpx/execution/executors/num\_cores.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

struct **num\_cores**

#include <num\_cores.hpp> Control number of cores in executors which need a functionality for setting the number of cores to be used by an algorithm directly

## Public Functions

inline explicit constexpr **num\_cores**(*std*::size\_t cores = 1) noexcept  
Construct a `num_cores` executor parameters object

---

**Note:** make sure the minimal number of cores is 1

---

namespace **parallel**

namespace **execution**

## hpx/execution/executors/persistent\_auto\_chunk\_size.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

struct **persistent\_auto\_chunk\_size**

*#include <persistent\_auto\_chunk\_size.hpp>* Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

### Public Functions

inline constexpr **persistent\_auto\_chunk\_size**(*std::uint64\_t num\_iters\_for\_timing = 0*)  
noexcept

Construct an **persistent\_auto\_chunk\_size** executor parameters object

---

**Note:** Default constructed **persistent\_auto\_chunk\_size** executor parameter types will use 0 microseconds as the execution time for each chunk and 80 microseconds as the minimal time for which any of the scheduled chunks should run.

---

inline explicit **persistent\_auto\_chunk\_size**(*hpx::chrono::steady\_duration const &time\_cs,*  
*std::uint64\_t num\_iters\_for\_timing = 0*) noexcept

Construct an **persistent\_auto\_chunk\_size** executor parameters object

**Parameters** **time\_cs** – The execution time for each chunk.

inline **persistent\_auto\_chunk\_size**(*hpx::chrono::steady\_duration const &time\_cs,*  
*hpx::chrono::steady\_duration const &rel\_time,*  
*std::uint64\_t num\_iters\_for\_timing = 0*) noexcept

Construct an **persistent\_auto\_chunk\_size** executor parameters object

**Parameters**

- **rel\_time** – [in] The time duration to use as the minimum to decide how many loop iterations should be combined.
- **time\_cs** – The execution time for each chunk.

namespace **parallel**

namespace **execution**

## hpx/execution/executors/polymorphic\_executor.hpp

```

```
template<typename ExPolicy, typename Executor, typename Parameters>
```

```
struct rebind_executor
```

*#include <rebind\_executor.hpp>* Rebind the type of executor used by an execution policy. The execution category of Executor shall not be weaker than that of ExecutionPolicy.

## Public Types

```
using type = typename policy_type::template rebind<executor_type, parameters_type>::type
```

The type of the rebound execution policy.

## hpx/execution/executors/static\_chunk\_size.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

```
struct static_chunk_size
```

*#include <static\_chunk\_size.hpp>* Loop iterations are divided into pieces of size *chunk\_size* and then assigned to threads. If *chunk\_size* is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

---

**Note:** This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.

---

## Public Functions

```
inline constexpr static_chunk_size() noexcept
Construct a static_chunk_size executor parameters object
```

---

**Note:** By default the number of loop iterations is determined from the number of available cores and the overall number of loop iterations to schedule.

---

```
inline explicit constexpr static_chunk_size(std::size_t chunk_size) noexcept
Construct a static_chunk_size executor parameters object
Parameters chunk_size – [in] The optional chunk size to use as the number of loop iterations to run on a single thread.
```

namespace **parallel**

    namespace **execution**

### `hpx/execution/traits/is_execution_policy.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

hpx::detail::is_sequenced_execution_policy<std::decay_t<T>>
```

```
#include <is_execution_policy.hpp> Extension: Detect whether given execution policy does not enable parallelization
```

i. The type `is_sequenced_execution_policy` can be used to detect non-parallel execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

ii. If  $T$  is the type of a standard or implementation-defined execution policy, `is_sequenced_execution_policy<T>` shall be publicly derived from `integral_constant<bool, true>`, otherwise from `integral_constant<bool, false>`.

iii. The behavior of a program that adds specializations for `is_sequenced_execution_policy` is undefined.

**execution\_base**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

**hpx/execution\_base/execution.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

struct **parallel\_execution\_tag**

`#include <execution.hpp>` Function invocations executed by a group of parallel execution agents execute in unordered fashion. Any such invocations executing in the same thread are indeterminately sequenced with respect to each other.

---

**Note:** `parallel_execution_tag` is weaker than `sequenced_execution_tag`.

---

struct **sequenced\_execution\_tag**

`#include <execution.hpp>` Function invocations executed by a group of sequential execution agents execute in sequential order.

struct **unsequenced\_execution\_tag**

`#include <execution.hpp>` Function invocations executed by a group of vector execution agents are permitted to execute in unordered fashion when executed in different threads, and un-sequenced with respect to one another when executed in the same thread.

---

**Note:** `unsequenced_execution_tag` is weaker than `parallel_execution_tag`.

---

namespace **parallel**

namespace **execution**

**Variables**

`hpx::parallel::execution::sync_execute_t sync_execute`

`hpx::parallel::execution::async_execute_t async_execute`

`hpx::parallel::execution::then_execute_t then_execute`

`hpx::parallel::execution::post_t post`

`hpx::parallel::execution::bulk_sync_execute_t bulk_sync_execute`

`hpx::parallel::execution::bulk_async_execute_t bulk_async_execute`

`hpx::parallel::execution::bulk_then_execute_t bulk_then_execute`

struct **async\_execute\_t** : public `hpx::functional::detail::tag_fallback<async_execute_t>`

`#include <execution.hpp>` Customization point for asynchronous execution agent creation.

This asynchronously creates a single function invocation `f()` using the associated executor.

---

**Note:** Executors have to implement only `async_execute()`. All other functions will be emulated by this or other customization points in terms of this single basic primitive. However, some executors will naturally specialize all operations for maximum efficiency.

---

**Note:** This is valid for one way executors (calls `make_ready_future(exec.sync_execute(f, ts...))` if it exists) and for two way executors (calls `exec.async_execute(f, ts...)` if it exists).

---

**Param exec** [in] The executor object to use for scheduling of the function `f`.

**Param f** [in] The function which will be scheduled using the given executor.

**Param ts** [in] Additional arguments to use to invoke `f`.

**Return** `f(ts...)`'s result through a future

## Private Functions

template<typename **Executor**, typename **F**, typename ...**Ts**>  
inline decltype(auto) friend **tag\_fallback\_invoke**(`async_execute_t`, **Executor** &&exec, **F**  
&&f, `Ts`&&... ts)

struct **bulk\_async\_execute\_t** : public

`hpx::functional::detail::tag_fallback<bulk_async_execute_t>`

`#include <execution.hpp>` Bulk form of asynchronous execution agent creation.

This asynchronously creates a group of function invocations `f(i)` whose ordering is given by the `execution_category` associated with the executor.

Here `i` takes on all values in the index space implied by shape. All exceptions thrown by invocations of `f(i)` are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This is deliberately different from the `bulk_async_execute` customization points specified in P0443. The `bulk_async_execute` customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

---

---

**Note:** This calls `exec.bulk_async_execute(f, shape, ts...)` if it exists; otherwise it executes `async_execute(f, shape, ts...)` as often as needed.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param f** [in] The function which will be scheduled using the given executor.

**Param shape** [in] The shape objects which defines the iteration boundaries for the arguments to be passed to *f*.

**Param ts** [in] Additional arguments to use to invoke *f*.

**Return** The return type of `executor_type::bulk_async_execute` if defined by `executor_type`. Otherwise a vector of futures holding the returned values of each invocation of *f*.

## Private Functions

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(bulk_async_execute_t, Executor &&exec,
                                              F &&f, Shape const &shape, Ts&&... ts)
```

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(bulk_async_execute_t, Executor &&exec,
                                              F &&f, Shape const &shape, Ts&&... ts)
```

```
struct bulk_sync_execute_t : public hpx::functional::detail::tag_fallback<bulk_sync_execute_t>
#include <execution.hpp> Bulk form of synchronous execution agent creation.
```

This synchronously creates a group of function invocations *f(i)* whose ordering is given by the `execution_category` associated with the executor. The function synchronizes the execution of all scheduled functions with the caller.

Here *i* takes on all values in the index space implied by `shape`. All exceptions thrown by invocations of *f(i)* are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This is deliberately different from the `bulk_sync_execute` customization points specified in P0443. The `bulk_sync_execute` customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

---

---

**Note:** This calls `exec.bulk_sync_execute(f, shape, ts...)` if it exists; otherwise it executes `sync_execute(f, shape, ts...)` as often as needed.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param f** [in] The function which will be scheduled using the given executor.

**Param shape** [in] The shape objects which defines the iteration boundaries for the arguments to be passed to *f*.

**Param ts** [in] Additional arguments to use to invoke *f*.

**Return** The return type of `executor_type::bulk_sync_execute` if defined by `executor_type`. Otherwise a vector holding the returned values of each invocation of *f* except when *f* returns void, which case void is returned.

## Private Functions

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(bulk_sync_execute_t, Executor &&exec,
                                                F &&f, Shape const &shape, Ts&&... ts)
```

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(bulk_sync_execute_t, Executor &&exec,
                                                F &&f, Shape const &shape, Ts&&... ts)
```

```
struct bulk_then_execute_t : public hpx::functional::detail::tag_fallback<bulk_then_execute_t>
#include <execution.hpp> Bulk form of execution agent creation depending on a given future.
```

This creates a group of function invocations  $f(i)$  whose ordering is given by the execution\_category associated with the executor.

Here  $i$  takes on all values in the index space implied by shape. All exceptions thrown by invocations of  $f(i)$  are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This is deliberately different from the then\_sync\_execute customization points specified in P0443. The bulk\_then\_execute customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

---

---

**Note:** This calls exec.bulk\_then\_execute(f, shape, pred, ts...) if it exists; otherwise it executes sync\_execute(f, shape, pred.share(), ts...) (if this executor is also an OneWayExecutor), or async\_execute(f, shape, pred.share(), ts...) (if this executor is also a TwoWayExecutor) - as often as needed.

---

**Param exec** [in] The executor object to use for scheduling of the function  $f$ .

**Param f** [in] The function which will be scheduled using the given executor.

**Param shape** [in] The shape objects which defines the iteration boundaries for the arguments to be passed to  $f$ .

**Param predecessor** [in] The future object the execution of the given function depends on.

**Param ts** [in] Additional arguments to use to invoke  $f$ .

**Return** The return type of  $executor\_type::bulk\_then\_execute$  if defined by  $executor\_type$ . Otherwise a vector holding the returned values of each invocation of  $f$ .

## Private Functions

```
template<typename Executor, typename F, typename Shape, typename Future, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(bulk_then_execute_t, Executor &&exec,
                                                F &&f, Shape const &shape, Future
                                                &&predecessor, Ts&&... ts)
```

```
template<typename Executor, typename F, typename Shape, typename Future, typename ...Ts>
```

---

```
inline decltype(auto) friend tag_fallback_invoke(bulk_then_execute_t, Executor &&exec,
                                              F &&f, Shape const &shape, Future
                                              &&predecessor, Ts&&... ts)
```

```
struct post_t : public hpx::functional::detail::tag_fallback<post_t>
{
    #include <execution.hpp> Customization point for asynchronous fire & forget execution agent creation.
```

This asynchronously (fire & forget) creates a single function invocation *f()* using the associated executor.

---

**Note:** This is valid for two way executors (calls *exec.post(f, ts...)*, if available, otherwise it calls *exec.async\_execute(f, ts...)* while discarding the returned future), and for non-blocking two way executors (calls *exec.post(f, ts...)* if it exists).

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param f** [in] The function which will be scheduled using the given executor.

**Param ts** [in] Additional arguments to use to invoke *f*.

## Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(post_t, Executor &&exec, F &&f,
                                              Ts&&... ts)
```

```
struct sync_execute_t : public hpx::functional::detail::tag_fallback<sync_execute_t>
{
    #include <execution.hpp> Customization point for synchronous execution agent creation.
```

This synchronously creates a single function invocation *f()* using the associated executor. The execution of the supplied function synchronizes with the caller

---

**Note:** This is valid for one way executors only, it will call *exec.sync\_execute(f, ts...)* if it exists.

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param f** [in] The function which will be scheduled using the given executor.

**Param ts** [in] Additional arguments to use to invoke *f*.

**Return** *f(ts...)*'s result

## Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(sync_execute_t, Executor &&exec, F
                                              &&f, Ts&&... ts)
```

```
struct then_execute_t : public hpx::functional::detail::tag_fallback<then_execute_t>
```

```
    #include <execution.hpp> Customization point for execution agent creation depending on a given future.
```

This creates a single function invocation *f()* using the associated executor after the given future object has become ready.

---

**Note:** This is valid for two way executors (calls `exec.then_execute(f, predecessor, ts...)` if it exists) and for one way executors (calls `predecessor.then(bind(f, ts...))`).

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param f** [in] The function which will be scheduled using the given executor.

**Param predecessor** [in] The future object the execution of the given function depends on.

**Param ts** [in] Additional arguments to use to invoke *f*.

**Return** *f(ts...)*'s result through a future

## Private Functions

```
template<typename Executor, typename F, typename Future, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(then_execute_t, Executor &&exec, F
&&f, Future &&predecessor, Ts&&... ts)
```

## hpx/execution\_base/receiver.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **execution**

        namespace **experimental**

## Functions

```
template<typename R, typename ...As>
void set_value(R &&r, As&&... as)
```

`set_value` is a customization point object. The expression `hpx::execution::set_value(r, as...)` is equivalent to:

- `r.set_value(as...)`, if that expression is valid. If the function selected does not send the value(s) `as...` to the Receiver `r`'s value channel, the program is ill-formed (no diagnostic required).
- Otherwise, ``set_value(r, as...)`, if that expression is valid, with overload resolution performed in a context that include the declaration `void set_value();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

```
template<typename R>
void set_stopped(R &&r)
```

`set_stopped` is a customization point object. The expression `hpx::execution::set_stopped(r)` is equivalent to:

- `r.set_stopped()`, if that expression is valid. If the function selected does not signal the Receiver `r`'s done channel, the program is ill-formed (no diagnostic required).
- Otherwise, ``set_stopped(r)`, if that expression is valid, with overload resolution performed in a context that include the declaration `void set_stopped();`
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

```
template<typename R, typename E>
void set_error(R &&r, E &&e)
```

`set_error` is a customization point object. The expression `hpx::execution::set_error(r, e)` is equivalent to:

- `r.set_stopped(e)`, if that expression is valid. If the function selected does not send the error `e` the Receiver `r`'s error channel, the program is ill-formed (no diagnostic required).
- Otherwise, ``set_error(r, e)`, if that expression is valid, with overload resolution performed in a context that include the declaration `void set_error()`;
- Otherwise, the expression is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`.

```

```
template<typename T, typename E>
```

```
struct is_receiver
```

#include <receiver.hpp> Receiving values from asynchronous computations is handled by the Receiver concept. A Receiver needs to be able to receive an error or be marked as being canceled. As such, the Receiver concept is defined by having the following two customization points defined, which form the completion-signal operations:

- `hpx::execution::experimental::set_stopped`
- `hpx::execution::experimental::set_error`

Those two functions denote the completion-signal operations. The Receiver contract is as follows:

- None of a Receiver's completion-signal operation shall be invoked before `hpx::execution::experimental::start` has been called on the operation state object that was returned by connecting a Receiver to a sender `hpx::execution::experimental::connect`.

- Once `hpx::execution::start` has been called on the operation state object, exactly one of the Receiver's completion-signal operation shall complete without an exception before the Receiver is destroyed

Once one of the Receiver's completion-signal operation has been completed without throwing an exception, the Receiver contract has been satisfied. In other words: The asynchronous operation has been completed.

**See also:**

`hpx::execution::experimental::is_receiver_of`

template<typename **T**, typename **CS**>

struct **is\_receiver\_of**

`#include <receiver.hpp>` The `receiver_of` concept is a refinement of the `Receiver` concept by requiring one additional completion-signal operation:

- `hpx::execution::set_value`

The `receiver_of` concept takes a receiver and an instance of the `completion_signatures`<> class template. The `receiver_of` concept, rather than accepting a receiver and some value types, is changed to take a receiver and an instance of the `completion_signatures`<> class template. A sender uses `completion_signatures`<> to describe the signals with which it completes. The `receiver_of` concept ensures that a particular receiver is capable of receiving those signals.

This completion-signal operation adds the following to the Receiver's contract:

- If `hpx::execution::set_value` exits with an exception, it is still valid to call `hpx::execution::set_error` or `hpx::execution::set_stopped`

### Typedefs

```
using current_executor = parallel::execution::thread_pool_executor
```

namespace **this\_thread**

### Functions

*parallel::execution::current\_executor get\_executor(error\_code &ec = throws)*

Returns a reference to the executor which was used to create the current thread.

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

namespace **threads**

### Functions

*parallel::execution::current\_executor get\_executor(thread\_id\_type const &id, error\_code &ec = throws)*

Returns a reference to the executor which was used to create the given thread.

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

## hpx/executors/execution\_policy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **execution**

### Typedefs

using **sequenced\_task\_policy** = detail::sequenced\_task\_policy\_shim<*sequenced\_executor*>

Extension: The class sequenced\_task\_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may not be parallelized (has to run sequentially).

The algorithm returns a future representing the result of the corresponding algorithm when invoked with the sequenced\_policy.

using **sequenced\_policy** = detail::sequenced\_policy\_shim<*sequenced\_executor*>

The class sequenced\_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm's execution may not be parallelized.

using **parallel\_task\_policy** = detail::parallel\_task\_policy\_shim<*parallel\_executor*>

Extension: The class parallel\_task\_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

The algorithm returns a future representing the result of the corresponding algorithm when invoked with the parallel\_policy.

using **parallel\_policy** = detail::parallel\_policy\_shim<*parallel\_executor*>

The class parallel\_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

using **parallel\_unsequenced\_task\_policy** =  
detail::parallel\_unsequenced\_task\_policy\_shim<*parallel\_executor*>

The class `parallel_unsequenced_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized and vectorized.

```
using parallel_unsequenced_policy =  
    detail::parallel_unsequenced_policy_shim<parallel_executor>
```

The class `parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized and vectorized.

```
using unsequenced_task_policy = detail::unsequenced_task_policy_shim<sequenced_executor>
```

The class `unsequenced_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be vectorized.

```
using unsequenced_policy = detail::unsequenced_policy_shim<sequenced_executor>
```

The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be vectorized.

## Variables

```
constexpr hpx::execution::experimental::to_task_t task = {}
```

Default sequential execution policy object.

```
constexpr hpx::execution::experimental::to_non_task_t non_task = {}
```

```
constexpr sequenced_policy seq = {}
```

Default sequential execution policy object.

```
constexpr parallel_policy par = {}
```

Default parallel execution policy object.

```
constexpr parallel_unsequenced_policy par_unseq = {}
```

Default vector execution policy object.

```
constexpr unsequenced_policy unseq = {}
```

Default vector execution policy object.

    Params &&params)
```

## hpx/executors/fork\_join\_executor.hpp

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

    namespace **execution**

        namespace **experimental**

### Functions

*std*::ostream &**operator<<**(*std*::ostream &os, *fork\_join\_executor*::**loop\_schedule** const &schedule)

class **fork\_join\_executor**

#include <*fork\_join\_executor.hpp*> An executor with fork-join (blocking) semantics.

The *fork\_join\_executor* creates on construction a set of worker threads that are kept alive for the duration of the executor. Copying the executor has reference semantics, i.e. copies of a *fork\_join\_executor* hold a reference to the worker threads of the original instance. Scheduling work through the executor concurrently from different threads is undefined behaviour.

The executor keeps a set of worker threads alive for the lifetime of the executor, meaning other work will not be executed while the executor is busy or waiting for work. The executor has a customizable delay after which it will yield to other work. Since starting and resuming the worker threads is a slow operation the executor should be reused whenever possible for multiple adjacent parallel algorithms or invocations of bulk\_(a)sync\_execute.

### Public Types

enum class **loop\_schedule**

Type of loop schedule for use with the *fork\_join\_executor*. *loop\_schedule*::**static\_** implies no work-stealing; *loop\_schedule*::**dynamic** allows stealing when a worker has finished its local work.

*Values:*

enumerator **static\_**

enumerator **dynamic**

## Public Functions

```
inline explicit fork_join_executor(threads::thread_priority priority =  

    threads::thread_priority::high, threads::thread_stacksize  

    stacksize = threads::thread_stacksize::small_,  

    loop_schedule schedule = loop_schedule::static_,  

    std::chrono::nanoseconds yield_delay =  

    std::chrono::milliseconds(1))
```

Construct a *fork\_join\_executor*.

### Parameters

- **priority** – The priority of the worker threads.
- **stacksize** – The stacksize of the worker threads. Must not be nostack.
- **schedule** – The loop schedule of the parallel regions.
- **yield\_delay** – The time after which the executor yields to other work if it hasn't received any new work for bulk execution.

namespace **parallel**

namespace **execution**

## hpx/executors/parallel\_executor.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

## TypeDefs

```
using parallel_executor = parallel_policy_executor<hpx::launch>
```

```
template<typename Policy>
```

```
struct parallel_policy_executor
```

```
#include <parallel_executor.hpp> A parallel_executor creates groups of parallel execution agents which execute in threads implicitly created by the executor. This executor prefers continuing with the creating thread first before executing newly created threads.
```

This executor conforms to the concepts of a *TwoWayExecutor*, and a *BulkTwoWayExecutor*

## Public Types

```
using execution_category = parallel_execution_tag
```

Associate the parallel\_execution\_tag executor tag type as a default with this executor.

```
using executor_parameters_type = static_chunk_size
```

Associate the static\_chunk\_size executor parameters type as a default with this executor.

## Public Functions

```
inline explicit constexpr parallel_policy_executor(threads::thread_priority priority,
                                                 threads::thread_stacksize stacksize =
                                                 threads::thread_stacksize::default_,
                                                 threads::thread_schedule_hint
                                                 schedulehint = {}, Policy1 = parallel::execution::detail::get_default_policy<Policy>::call(),
                                                 std::size_t hierarchical_threshold =
                                                 hierarchical_threshold_default_)
```

Create a new parallel executor.

```
inline explicit constexpr parallel_policy_executor(threads::thread_stacksize stacksize,
                                                 threads::thread_schedule_hint
                                                 schedulehint = {}, Policy1 = parallel::execution::detail::get_default_policy<Policy>::call())
```

```
inline explicit constexpr parallel_policy_executor(threads::thread_schedule_hint
                                                 schedulehint, Policy1 = parallel::execution::detail::get_default_policy<Policy>::call())
```

```
inline explicit constexpr parallel_policy_executor(Policy1 = parallel::execution::detail::get_default_policy<Policy>::call())
```

```
inline explicit constexpr parallel_policy_executor(threads::thread_pool_base *pool,
                                                 threads::thread_priority priority =
                                                 threads::thread_priority::default_,
                                                 threads::thread_stacksize stacksize =
                                                 threads::thread_stacksize::default_,
                                                 threads::thread_schedule_hint
                                                 schedulehint = {}, Policy1 = parallel::execution::detail::get_default_policy<Policy>::call(),
                                                 std::size_t hierarchical_threshold =
                                                 hierarchical_threshold_default_)
```

## hpx/executors/parallel\_executor\_aggregated.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

template<>

```
struct hpx::parallel::execution::parallel_policy_executor_aggregated<hpx::launch>
```

### Public Types

```
using execution_category = hpx::execution::parallel_execution_tag
```

Associate the parallel\_execution\_tag executor tag type as a default with this executor.

```
using executor_parameters_type = hpx::execution::static_chunk_size
```

Associate the static\_chunk\_size executor parameters type as a default with this executor.

### Public Functions

```
inline explicit constexpr parallel_policy_executor_aggregated(hpx::launch l =
    hpx::launch::async_policy{},  
    std::size_t spread = 4, std::size_t tasks  
    = std::size_t(-1))
```

Create a new parallel executor.

```
template<typename F, typename S, typename ...Ts>  
inline auto bulk_async_execute(F &&f, S const &shape, Ts&&... ts) const
```

namespace **hpx**

    namespace **parallel**

        namespace **execution**

### Typedefs

```
using parallel_executor_aggregated =  
parallel_policy_executor_aggregated<hpx::launch::async_policy>
```

```
template<typename Policy = hpx::launch::async_policy>
```

```
struct parallel_policy_executor_aggregated
```

#include <parallel\_executor\_aggregated.hpp> A *parallel\_executor\_aggregated* creates groups of parallel execution agents that execute in threads implicitly created by the executor. This executor prefers continuing with the creating thread first before executing newly created threads.

This executor conforms to the concepts of a TwoWayExecutor, and a BulkTwoWayExecutor

## Public Types

```
using execution_category = hpx::execution::parallel_execution_tag
```

Associate the parallel\_execution\_tag executor tag type as a default with this executor.

```
using executor_parameters_type = hpx::execution::static_chunk_size
```

Associate the static\_chunk\_size executor parameters type as a default with this executor.

## Public Functions

```
inline explicit constexpr parallel_policy_executor_aggregated(std::size_t spread = 4,  
                                                 std::size_t tasks =  
                                                 std::size_t(-1))
```

Create a new parallel executor.

```
template<typename F, typename S, typename ...Ts>  
inline std::vector<hpx::future<void>> bulk_async_execute(F &&f, S const &shape, Ts&&...  
                                         ts) const
```

```
template<> launch >
```

## Public Types

```
using execution_category = hpx::execution::parallel_execution_tag
```

Associate the parallel\_execution\_tag executor tag type as a default with this executor.

```
using executor_parameters_type = hpx::execution::static_chunk_size
```

Associate the static\_chunk\_size executor parameters type as a default with this executor.

## Public Functions

```
inline explicit constexpr parallel_policy_executor_aggregated(hpx::launch l =  
                                                 hpx::launch::async_policy{},

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **execution**

        namespace **experimental**

**struct thread\_pool\_scheduler**

## Public Functions

```
constexpr thread_pool_scheduler() = default  
inline explicit thread_pool_scheduler(hpx::threads::thread_pool_base *pool)
```

### **hpx/executors/datapar/execution\_policy.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

### **hpx/executors/datapar/execution\_policy\_mappings.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

## filesystem

See *Public API* for a list of names and headers that are part of the public *HPX API*.

### **hpx/modules/filesystem.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

This file provides a compatibility layer using Boost.Filesystem for the C++17 filesystem library. It is *not* intended to be a complete compatibility layer. It only contains functions required by the HPX codebase. It also provides some functions only available in Boost.Filesystem when using C++17 filesystem.

namespace **hpx**

    namespace **filesystem**

### Functions

```
inline path initial_path()  
inline std::string basename(path const &p)  
inline path canonical(path const &p, path const &base)  
inline path canonical(path const &p, path const &base, std::error_code &ec)
```

namespace **filesystem**

## functional

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/functional/invoke.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

#### Defines

`HPX_INVOKE_R(R, F, ...)`

namespace `hpx`

namespace `util`

#### Functions

```
template<typename F, typename ...Ts>
constexpr util::invoke_result<F, Ts...>::type invoke(F &&f, Ts&&... vs) noexcept
    noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(F,
        f), HPX_FORWARD(Ts, vs)...)))
```

Invokes the given callable object f with the content of the argument pack vs

---

**Note:** This function is similar to `std::invoke` (C++17)

---

#### Parameters

- **f** – Requires to be a callable object. If f is a member function pointer, the first argument in the pack will be treated as the callee (this object).
- **vs** – An arbitrary pack of arguments

**Throws** `std::exception` – like objects thrown by call to object f with the argument types vs.

**Returns** The result of the callable object when it's called with the given argument types.

```
template<typename R, typename F, typename ...Ts>
constexpr R invoke_r(F &&f, Ts&&... vs) noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(F,
    f), HPX_FORWARD(Ts, vs)...)))
```

**Template Parameters** **R** – The result type of the function when it's called with the content of the given argument types vs.

namespace `functional`

struct `invoke`

## Public Functions

```
template<typename F, typename ...Ts>
inline constexpr util::invoke\_result<F, Ts...>::type operator()(F &&f, Ts&&... vs) const
    noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(f), HPX_FORWARD(Ts,
        vs)...)))
```

```
template<typename R>
struct invoke_r
```

## Public Functions

```
template<typename F, typename ...Ts>
inline constexpr R operator()(F &&f, Ts&&... vs) const
    noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(F, f),
        HPX_FORWARD(Ts, vs)...)))
```

## [hpx/functional/invoke\\_fused.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public *HPX API*.

namespace **hpx**

namespace **util**

## Functions

```
template<typename F, typename Tuple>
constexpr detail::invoke_fused_result<F, Tuple>::type invoke_fused(F &&f, Tuple &&t) noexcept
    noexcept(detail::invoke_fused_impl(detail::fused(
        HPX_FORWARD(F, f),
        HPX_FORWARD(Tuple, t))))
```

Invokes the given callable object f with the content of the sequenced type t (tuples, pairs)

---

**Note:** This function is similar to `std::apply` (C++17)

---

### Parameters

- **f** – Must be a callable object. If f is a member function pointer, the first argument in the sequenced type will be treated as the callee (this object).
- **t** – A type whose contents are accessible through a call to `hpx::get`.

**Throws** `std::exception` – like objects thrown by call to object f with the arguments contained in the sequenceable type t.

**Returns** The result of the callable object when it's called with the content of the given sequenced type.

template<typename R, typename F, typename Tuple>

```
constexpr R invoke_fused_r(F &&f, Tuple &&t) noexcept
    noexcept(noexcept(detail::invoke_fused_impl(detail::fused_index_pack_t<Tuple>{}, HPX_FORWARD(F, f), HPX_FORWARD(Tuple, t))))
```

**Template Parameters** **R** – The result type of the function when it's called with the content of the given sequenced type.

## futures

typedef hpx::future<R> instead
```

namespace **lcos**

## io\_service

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

### hpx/io\_service/io\_service\_pool.hpp

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

```
class io_service_pool
```

```
#include <io_service_pool.hpp> A pool of io_service objects.
```

## Public Functions

```
HPX_NON_COPYABLE(io_service_pool)

explicit io_service_pool(std::size_t pool_size = 2, threads::policies::callback_notifier const
    &notifier = threads::policies::callback_notifier(), char const
    *pool_name = "", char const *name_postfix = "")

Construct the io_service pool.

Parameters

- pool_size – [in] The number of threads to run to serve incoming requests
- start_thread – [in]

explicit io_service_pool(threads::policies::callback_notifier const &notifier, char const
    *pool_name = "", char const *name_postfix = "")

Construct the io_service pool.

Parameters start_thread – [in]

~io_service_pool()

bool run(bool join_threads = true, barrier *startup = nullptr)

Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to
complete

bool run(std::size_t num_threads, bool join_threads = true, barrier *startup = nullptr)

Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to
complete

void stop()

Stop all io_service objects in the pool.

void join()

Join all io_service threads in the pool.

void clear()

Clear all internal data structures.

void wait()

Wait for all work to be done.

bool stopped()

asio::io_context &get_io_service(int index = -1)

Get an io_service to use.

std::thread &get_os_thread_handle(std::size_t thread_num)

access underlying thread handle

inline std::size_t size() const

Get number of threads associated with this I/O service.

void thread_run(std::size_t index, barrier *startup = nullptr)

Activate the thread index for this thread pool.

inline char const *get_name() const

Return name of this pool.

void init(std::size_t pool_size)
```

## Protected Functions

```
bool run_locked(std::size_t num_threads, bool join_threads, barrier *startup)  
void stop_locked()  
void join_locked()  
void clear_locked()  
void wait_locked()
```

## Private Types

```
using io_service_ptr = std::unique_ptr<asio::io_context>  
using work_type = asio::io_context::work
```

## Private Functions

```
inline work_type initialize_work(asio::io_context &io_service)
```

## Private Members

*std*::mutex **mtx\_**

*std*::vector<*io\_service\_ptr*> **io\_services\_**

The pool of io\_services.

*std*::vector<*std*::thread> **threads\_**

*std*::vector<*work\_type*> **work\_**

The work that keeps the io\_services running.

*std*::size\_t **next\_io\_service\_**

The next io\_service to use for a connection.

bool **stopped\_**

set to true if stopped

*std*::size\_t **pool\_size\_**

initial number of OS threads to execute in this pool

*threads::policies*::callback\_notifier const &**notifier\_**

call this for each thread start/stop

```

char const *pool_name_
char const *pool_name_postfix_
bool waiting_
    Set to true if waiting for work to finish.

std::unique_ptr<barrier> wait_barrier_
std::unique_ptr<barrier> continue_barrier_

```

## lcos\_local

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/lcos\_local/and\_gate.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **lcos**

namespace **local**

```
struct and_gate : public hpx::lcos::local::base_and_gate<hpx::no_mutex>
```

#### Public Functions

```

inline and_gate(std::size_t count = 0)
inline and_gate(and_gate &&rhs) noexcept
inline and_gate &operator=(and_gate &&rhs) noexcept
template<typename Lock>
inline hpx::future<void> get_future(Lock &l, std::size_t count = std::size_t(-1), std::size_t

## pack\_traversal

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/pack\_traversal/pack\_traversal.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

## Functions

```
template<typename Mapper, typename... T> <unspecified> map_pack(Mapper &&mapper, T &&... pack)
```

Maps the pack with the given mapper.

This function tries to visit all plain elements which may be wrapped in:

- homogeneous containers (`std::vector`, `std::list`)
- heterogeneous containers (`hpx::tuple`, `std::pair`, `std::array`) and re-assembles the pack with the result of the mapper. Mapping from one type to a different one is supported.

Elements that aren't accepted by the mapper are routed through and preserved through the hierarchy.

```
// Maps all integers to floats
map_pack([](int value) {
    return float(value);
},
1, hpx::make_tuple(2, std::vector<int>{3, 4}), 5);
```

**Throws** `std::exception` – like objects which are thrown by an invocation to the mapper.

**Parameters**

- **mapper** – A callable object, which accept an arbitrary type and maps it to another type or the same one.
- **pack** – An arbitrary variadic pack which may contain any type.

**Returns** The mapped element or in case the pack contains multiple elements, the pack is wrapped into a `hpx::tuple`.

## hpx/pack\_traversal/pack\_traversal\_async.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

namespace `util`

### Functions

```
template<typename Visitor, typename ...T>
auto traverse_pack_async(Visitor &&visitor, T&&... pack) ->
    decltype(detail::apply_pack_transform_async(HPX_FORWARD(Visitor,
    visitor), HPX_FORWARD(T, pack)...))
```

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
struct my_async_visitor
{
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }
```

(continues on next page)

(continued from previous page)

```
template <typename T>
void operator()(async_traverse_complete_tag, T&& pack)
{
}
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

#### Parameters

- **visitor** – A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should must have a virtual destructor!
- **pack** – The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.

**Returns** A `hpx::intrusive_ptr` that references an instance of the given visitor object.

```
template<typename Allocator, typename Visitor, typename ...T>
auto traverse_pack_async_allocator(Allocator const &alloc, Visitor &&visitor, T &&... pack) ->
    de-
    cltype(detail::apply_pack_transform_async_allocator(alloc,
        HPX_FORWARD(Visitor, visitor), HPX_FORWARD(T,
            pack)...))
```

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
struct my_async_visitor
{
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }

    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

#### Parameters

- **visitor** – A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should must have a virtual destructor!

- **pack** – The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.
- **alloc** – Allocator instance to use to create the traversal frame.

**Returns** A hpx::intrusive\_ptr that references an instance of the given visitor object.

## hpx/pack\_traversal/unwrap.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ...Args>
auto unwrap(Args&&... args) -> decltype(util::detail::unwrap_depth_impl<1U>(HPX_FORWARD(Args,
args)...))
```

A helper function for retrieving the actual result of any hpx::future like type which is wrapped in an arbitrary way.

Unwraps the given pack of arguments, so that any hpx::future object is replaced by its future result type in the argument pack:

- `hpx::future<int> -> int`
- `hpx::future<std::vector<float>> -> std::vector<float>`
- `std::vector<future<float>> -> std::vector<float>`

The function is capable of unwrapping hpx::future like objects that are wrapped inside any container or tuple like type, see `hpx::util::map_pack()` for a detailed description about which surrounding types are supported. Non hpx::future like types are permitted as arguments and passed through.

```
// Single arguments
int i1 = hpx::unwrap(hpx::make_ready_future(0));

// Multiple arguments
hpx::tuple<int, int> i2 =
    hpx::unwrap(hpx::make_ready_future(1),
                hpx::make_ready_future(2));
```

---

**Note:** This function unwraps the given arguments until the first traversed nested hpx::future which corresponds to an unwrapping depth of one. See `hpx::unwrap_n()` for a function which unwraps the given arguments to a particular depth or `hpx::unwrap_all()` that unwraps all future like objects recursively which are contained in the arguments.

---

**Parameters** `args` – the arguments that are unwrapped which may contain any arbitrary future or non future type.

**Throws** `std::exception` – like objects in case any of the given wrapped hpx::future objects were resolved through an exception. See `hpx::future::get()` for details.

**Returns** Depending on the count of arguments this function returns a hpx::tuple containing the unwrapped arguments if multiple arguments are given. In case the function is called with a single argument, the argument is unwrapped and returned.

```
template<std::size_t Depth, typename ...Args>
auto unwrap_n(Args&&... args) ->
    decltype(util::detail::unwrap_depth_impl<Depth>(HPX_FORWARD(Args, args)...))
```

An alterntive version of hpx::unwrap(), which unwraps the given arguments to a certain depth of hpx::future like objects.

See unwrap for a detailed description.

**Template Parameters Depth** – The count of hpx::future like objects which are unwrapped maxmally.

```
template<typename ...Args>
auto unwrap_all(Args&&... args) ->
    decltype(util::detail::unwrap_depth_impl<0U>(HPX_FORWARD(Args, args)...))
```

An alterntive version of hpx::unwrap(), which unwraps the given arguments recursively so that all contained hpx::future like objects are replaced by their actual value.

See hpx::unwrap() for a detailed description.

```
template<typename T>
auto unwrapping(T &&callable) ->
    decltype(util::detail::functional_unwrap_depth_impl<1U>(HPX_FORWARD(T, callable)))
```

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap() function and then passes the result to the given callable object.

```
auto callable = hpx::unwrapping([](int left, int right) {
    return left + right;
});

int i1 = callable(hpx::make_ready_future(1),
                  hpx::make_ready_future(2));
```

See hpx::unwrap() for a detailed description.

**Parameters callable** – the callable object which which is called with the result of the corresponding unwrap function.

```
template<std::size_t Depth, typename T>
auto unwrapping_n(T &&callable) ->
    decltype(util::detail::functional_unwrap_depth_impl<Depth>(HPX_FORWARD(T,
        callable)))
```

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap\_n() function and then passes the result to the given callable object.

See hpx::unwrapping() for a detailed description.

```
template<typename T>
auto unwrapping_all(T &&callable) ->
    decltype(util::detail::functional_unwrap_depth_impl<0U>(HPX_FORWARD(T,
        callable)))
```

Returns a callable object which unwraps its arguments upon invocation using the `hpx::unwrap_all()` function and then passes the result to the given callable object.

See `hpx::unwrapping()` for a detailed description.

namespace **functional**

struct **unwrap**

`#include <unwrap.hpp>` A helper function object for functionally invoking `hpx::unwrap`. For more information please refer to its documentation.

struct **unwrap\_all**

`#include <unwrap.hpp>` A helper function object for functionally invoking `hpx::unwrap_all`. For more information please refer to its documentation.

template<`std`::size\_t **Depth**>

struct **unwrap\_n**

`#include <unwrap.hpp>` A helper function object for functionally invoking `hpx::unwrap_n`. For more information please refer to its documentation.

namespace **util**

## Functions

template<typename ...**Args**>  
auto **unwrap**(*Args*&&... args) -> decltype(detail::unwrap\_depth\_impl<1U>(HPX\_FORWARD(*Args*,  
*args*...)))

template<`std`::size\_t **Depth**, typename ...**Args**>  
auto **unwrap\_n**(*Args*&&... args) ->  
    decltype(detail::unwrap\_depth\_impl<**Depth**>(HPX\_FORWARD(*Args*, *args*...)))

template<typename ...**Args**>  
auto **unwrap\_all**(*Args*&&... args) ->  
    decltype(detail::unwrap\_depth\_impl<0U>(HPX\_FORWARD(*Args*, *args*...)))

template<typename **T**>

template<typename **T**>  
auto **unwrapping\_all**(*T* &&callable) ->  
    decltype(detail::functional\_unwrap\_depth\_impl<0U>(HPX\_FORWARD(*T*,  
*callable*)))

---

namespace **functional**

### Functions

```
struct HPX_DEPRECATED_V (1, 7, "Please use hpx::functional::unwrap instead.  
") unwrap
```

### preprocessor

See [Public API](#) for a list of names and headers that are part of the public *HPX API*.

### hpx/preprocessor/cat.hpp

See [Public API](#) for a list of names and headers that are part of the public *HPX API*.

#### Defines

##### **HPX\_PP\_CAT(A, B)**

Concatenates the tokens A and B into a single token. Evaluates to AB

#### Parameters

- **A** – First token
- **B** – Second token

### hpx/preprocessor/expand.hpp

See [Public API](#) for a list of names and headers that are part of the public *HPX API*.

#### Defines

##### **HPX\_PP\_EXPAND(X)**

The HPX\_PP\_EXPAND macro performs a double macro-expansion on its argument.

This macro can be used to produce a delayed preprocessor expansion.

Example:

```
#define MACRO(a, b, c) (a)(b)(c)
#define ARGS() (1, 2, 3)

HPX_PP_EXPAND(MACRO ARGS()) // expands to (1)(2)(3)
```

#### Parameters

- **X** – Token to be expanded twice

## hpx/preprocessor/nargs.hpp

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

### Defines

#### HPX\_PP\_NARGS(...)

Expands to the number of arguments passed in

Example Usage:

```
HPX_PP_NARGS(hpx, pp, nargs)
HPX_PP_NARGS(hpx, pp)
HPX_PP_NARGS(hpx)
```

Expands to:

```
3
2
1
```

### Parameters

- ... – The variadic number of arguments

## hpx/preprocessor/stringize.hpp

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

### Defines

#### HPX\_PP\_STRINGIZE(X)

The *HPX\_PP\_STRINGIZE* macro stringizes its argument after it has been expanded.

The passed argument X will expand to "X". Note that the stringizing operator (#) prevents arguments from expanding. This macro circumvents this shortcoming.

### Parameters

- X – The text to be converted to a string literal

## hpx/preprocessor/strip\_parens.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

#### `HPX_PP_STRIP_PARENS(X)`

For any symbol X, this macro returns the same symbol from which potential outer parens have been removed. If no outer parens are found, this macros evaluates to X itself without error.

The original implementation of this macro is from Steven Watanbe as shown in <http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976>

```
HPX_PP_STRIP_PARENS(no_parens)
HPX_PP_STRIP_PARENS((with_parens))
```

#### Example Usage:

This produces the following output

```
no_parens
with_parens
```

### Parameters

- **X** – Symbol to strip parens from

## resiliency

## runtime\_configuration

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/runtime\_configuration/component\_commandline\_base.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

#### Defines

**HPX\_REGISTER\_COMMANDLINE\_REGISTRY(RegistryType, componentname)**

The macro *HPX\_REGISTER\_COMMANDLINE\_REGISTRY* is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

**HPX\_REGISTER\_COMMANDLINE\_REGISTRY\_DYNAMIC(RegistryType, componentname)**

**HPX\_REGISTER\_COMMANDLINE\_OPTIONS()**

The macro *HPX\_REGISTER\_COMMANDLINE\_OPTIONS* is used to define the required Hpx.Plugin entry point for the command line option registry. This macro has to be used in not more than one compilation unit of a component module.

**HPX\_REGISTER\_COMMANDLINE\_OPTIONS\_DYNAMIC()**

namespace **hpx**

namespace **components**

struct **component\_commandline\_base**

#include <component\_commandline\_base.hpp> The `component_commandline_base` has to be used as a base class for all component command-line line handling registries.

#### Public Functions

virtual ~**component\_commandline\_base**() = default

virtual [hpx::program\\_options::options\\_description](#) **add\_commandline\_options**() = 0

Return any additional command line options valid for this component.

---

**Note:** This function will be executed by the runtime system during system startup.

---

**Returns** The module is expected to fill a `options_description` object with any additional command line options this component will handle.

## hpx/runtime\_configuration/component\_registry\_base.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

**HPX\_REGISTER\_COMPONENT\_REGISTRY**(RegistryType, componentname)

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

**HPX\_REGISTER\_COMPONENT\_REGISTRY\_DYNAMIC**(RegistryType, componentname)

**HPX\_REGISTER\_REGISTRY\_MODULE()**

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

**HPX\_REGISTER\_REGISTRY\_MODULE\_DYNAMIC()**

namespace **hpx**

namespace **components**

struct **component\_registry\_base**

#include <component\_registry\_base.hpp> The `component_registry_base` has to be used as a base class for all component registries.

### Public Functions

inline virtual ~**component\_registry\_base**()

virtual bool **get\_component\_info**(*std*::vector<*std*::string> &fillini, *std*::string const &filepath, bool is\_static = false) = 0

Return the ini-information for all contained components.

**Parameters** **fillini** – [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

**Returns** Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

virtual void **register\_component\_type**() = 0

Return the unique identifier of the component type this factory is responsible for.

**Parameters**

- **locality** – [in] The id of the locality this factory is responsible for.
- **agas\_client** – [in] The AGAS client to use for component id registration (if needed).

**Returns** Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.

## hpx/runtime\_configuration/plugin\_registry\_base.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

**HPX\_REGISTER\_PLUGIN\_BASE\_REGISTRY(PluginType, name)**

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_MODULE()**

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_MODULE\_DYNAMIC()**

namespace **hpx**

namespace **plugins**

struct **plugin\_registry\_base**

#include <plugin\_registry\_base.hpp> The `plugin_registry_base` has to be used as a base class for all plugin registries.

### Public Functions

inline virtual ~**plugin\_registry\_base**()

virtual bool **get\_plugin\_info**(*std*::vector<*std*::string> &fillini) = 0

Return the configuration information for any plugin implemented by this module

**Parameters** `fillini` – [in, out] The module is expected to fill this vector with the initialization information (one line per vector element) for all plugins implemented in this module.

**Returns** Returns `true` if the parameter `fillini` has been successfully initialized with the registry data of all implemented in this module.

inline virtual void **init**(int\*, char\*\*\*, *util*::runtime\_configuration&)

## hpx/runtime\_configuration/runtime\_mode.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Enums

enum class **runtime\_mode**

A HPX runtime can be executed in two different modes: console mode and worker mode.

*Values:*

enumerator **invalid**

enumerator **console**

The runtime is the console locality.

enumerator **worker**

The runtime is a worker locality.

enumerator **connect**

The runtime is a worker locality connecting late

enumerator **local**

The runtime is fully local.

enumerator **default\_**

The runtime mode will be determined based on the command line arguments

enumerator **last**

## Functions

char const \***get\_runtime\_mode\_name**(*runtime\_mode* state)

Get the readable string representing the name of the given runtime\_mode constant.

*runtime\_mode* **get\_runtime\_mode\_from\_name**(*std::string* const &mode)

Returns the internal representation (runtime\_mode constant) from the readable string representing the name.

This represents the internal representation from the readable string representing the name.

**Parameters** **mode** – this represents the runtime mode

## **runtime\_local**

See *Public API* for a list of names and headers that are part of the public HPX API.

## hpx/runtime\_local/component\_startup\_shutdown\_base.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

**HPX\_REGISTER\_STARTUP\_SHUTDOWN\_REGISTRY**(RegistryType, componentname)

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

**HPX\_REGISTER\_STARTUP\_SHUTDOWN\_REGISTRY\_DYNAMIC**(RegistryType, componentname)

**HPX\_REGISTER\_STARTUP\_SHUTDOWN\_FUNCTIONS()**

This macro is used to define the required Hpx.Plugin entry point for the startup/shutdown registry. This macro has to be used in not more than one compilation unit of a component module.

**HPX\_REGISTER\_STARTUP\_SHUTDOWN\_FUNCTIONS\_DYNAMIC()**

namespace **hpx**

namespace **components**

struct **component\_startup\_shutdown\_base**

#include <component\_startup\_shutdown\_base.hpp> The [component\\_startup\\_shutdown\\_base](#) has to be used as a base class for all component startup/shutdown registries.

### Public Functions

virtual ~[component\\_startup\\_shutdown\\_base](#)() = default

virtual bool **get\_startup\_function**([startup\\_function\\_type](#) &startup, bool &pre\_startup) = 0

Return any startup function for this component.

**Parameters** **startup** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

**Returns** Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

virtual bool **get\_shutdown\_function**([shutdown\\_function\\_type](#) &shutdown, bool &pre\_shutdown) = 0

Return any shutdown function for this component.

**Parameters** **shutdown** – [in, out] The module is expected to fill this function object with a reference to a shutdown function. This function will be executed by the runtime system during system shutdown.

**Returns** Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

## hpx/runtime\_local/custom\_exception\_info.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

`std::string diagnostic_information(exception_info const &xi)`

Extract the diagnostic information embedded in the given exception and return a string holding a formatted message.

The function `hpx::diagnostic_information` can be used to extract all diagnostic information stored in the given exception instance as a formatted string. This simplifies debug output as it composes the diagnostics into one, easy to use function call. This includes the name of the source file and line number, the sequence number of the OS-thread and the HPX-thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

#### See also:

`hpx::get_error_locality_id()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_thread_description()`,  
`hpx::get_error()`,      `hpx::get_error_backtrace()`,      `hpx::get_error_env()`,      `hpx::get_error_what()`,  
`hpx::get_error_config()`, `hpx::get_error_state()`

**Parameters** `xi` – The parameter `e` will be inspected for all diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if any of the required allocation operations fail)

**Returns** The formatted string holding all of the available diagnostic information stored in the given exception instance.

`std::uint32_t get_error_locality_id(hpx::exception_info const &xi)`

Return the locality id where the exception was thrown.

The function `hpx::get_error_locality_id` can be used to extract the diagnostic information element representing the locality id as stored in the given exception instance.

#### See also:

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_thread_description()`,  
`hpx::get_error()`,      `hpx::get_error_backtrace()`,      `hpx::get_error_env()`,      `hpx::get_error_what()`,  
`hpx::get_error_config()`, `hpx::get_error_state()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** nothing –

**Returns** The locality id of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return `hpx::naming::invalid_locality_id`.

`std::string get_error_host_name(hpx::exception_info const &xi)`

Return the hostname of the locality where the exception was thrown.

The function `hpx::get_error_host_name` can be used to extract the diagnostic information element representing the host name as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`,    `hpx::get_error_process_id()`,    `hpx::get_error_function_name()`,  
`hpx::get_error_file_name()`,    `hpx::get_error_line_number()`,    `hpx::get_error_os_thread()`,  
`hpx::get_error_thread_id()`,    `hpx::get_error_thread_description()`,    `hpx::get_error()`,  
`hpx::get_error_backtrace()`,    `hpx::get_error_env()`,    `hpx::get_error_what()`,    `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The hostname of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return empty string.

`std::int64_t get_error_process_id(hpx::exception_info const &xi)`

Return the (operating system) process id of the locality where the exception was thrown.

The function `hpx::get_error_process_id` can be used to extract the diagnostic information element representing the process id as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`,    `hpx::get_error_host_name()`,    `hpx::get_error_function_name()`,  
`hpx::get_error_file_name()`,    `hpx::get_error_line_number()`,    `hpx::get_error_os_thread()`,  
`hpx::get_error_thread_id()`,    `hpx::get_error_thread_description()`,    `hpx::get_error()`,  
`hpx::get_error_backtrace()`,    `hpx::get_error_env()`,    `hpx::get_error_what()`,    `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** nothing –

**Returns** The process id of the OS-process which threw the exception If the exception instance does not hold this information, the function will return 0.

`std::string get_error_env(hpx::exception_info const &xi)`

Return the environment of the OS-process at the point the exception was thrown.

The function `hpx::get_error_env` can be used to extract the diagnostic information element representing the environment of the OS-process collected at the point the exception was thrown.

**See also:**

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_thread_description()`,  
`hpx::get_error()`,      `hpx::get_error_backtrace()`,      `hpx::get_error_what()`,      `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The environment from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_backtrace(hpx::exception_info const &xi)`

Return the stack backtrace from the point the exception was thrown.

The function `hpx::get_error_backtrace` can be used to extract the diagnostic information element representing the stack backtrace collected at the point the exception was thrown.

**See also:**

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_thread_description()`,  
`hpx::get_error()`,      `hpx::get_error_env()`,      `hpx::get_error_what()`,      `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The stack back trace from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::size_t get_error_os_thread(hpx::exception_info const &xi)`

Return the sequence number of the OS-thread used to execute HPX-threads from which the exception was thrown.

The function `hpx::get_error_os_thread` can be used to extract the diagnostic information element representing the sequence number of the OS-thread as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information()*,      *hpx::get\_error\_host\_name()*,      *hpx::get\_error\_process\_id()*,  
*hpx::get\_error\_function\_name()*,      *hpx::get\_error\_file\_name()*,      *hpx::get\_error\_line\_number()*,  
*hpx::get\_error\_thread\_id()*,      *hpx::get\_error\_thread\_description()*,      *hpx::get\_error()*,  
*hpx::get\_error\_backtrace()*,    *hpx::get\_error\_env()*,    *hpx::get\_error\_what()*,    *hpx::get\_error\_config()*,  
*hpx::get\_error\_state()*

**Parameters xi** – The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

**Throws nothing** –

**Returns** The sequence number of the OS-thread used to execute the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return *std::size(-1)*.

*std::size\_t get\_error\_thread\_id([hpx::exception\\_info const &xi](#))*

Return the unique thread id of the HPX-thread from which the exception was thrown.

The function *hpx::get\_error\_thread\_id* can be used to extract the diagnostic information element representing the HPX-thread id as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information()*,      *hpx::get\_error\_host\_name()*,      *hpx::get\_error\_process\_id()*,  
*hpx::get\_error\_function\_name()*,      *hpx::get\_error\_file\_name()*,      *hpx::get\_error\_line\_number()*,  
*hpx::get\_error\_os\_thread()*              *hpx::get\_error\_thread\_description()*,      *hpx::get\_error()*,  
*hpx::get\_error\_backtrace()*,    *hpx::get\_error\_env()*,    *hpx::get\_error\_what()*,    *hpx::get\_error\_config()*,  
*hpx::get\_error\_state()*

**Parameters xi** – The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

**Throws nothing** –

**Returns** The unique thread id of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return *std::size\_t(0)*.

*std::string get\_error\_thread\_description([hpx::exception\\_info const &xi](#))*

Return any additionally available thread description of the HPX-thread from which the exception was thrown.

The function *hpx::get\_error\_thread\_description* can be used to extract the diagnostic information element representing the additional thread description as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information()*,      *hpx::get\_error\_host\_name()*,      *hpx::get\_error\_process\_id()*,  
*hpx::get\_error\_function\_name()*,      *hpx::get\_error\_file\_name()*,      *hpx::get\_error\_line\_number()*,  
*hpx::get\_error\_os\_thread()*,              *hpx::get\_error\_thread\_id()*,      *hpx::get\_error\_backtrace()*,

`hpx::get_error_env()`,      `hpx::get_error()`,      `hpx::get_error_state()`,      `hpx::get_error_what()`,  
`hpx::get_error_config()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** Any additionally available thread description of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_config(hpx::exception_info const &xi)`

Return the HPX configuration information point from which the exception was thrown.

The function `hpx::get_error_config` can be used to extract the HPX configuration information element representing the full HPX configuration information as stored in the given exception instance.

#### See also:

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_backtrace()`,  
`hpx::get_error_env()`,      `hpx::get_error()`,      `hpx::get_error_state()`,      `hpx::get_error_what()`,  
`hpx::get_error_thread_description()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** Any additionally available HPX configuration information the point from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_state(hpx::exception_info const &xi)`

Return the HPX runtime state information at which the exception was thrown.

The function `hpx::get_error_state` can be used to extract the HPX runtime state information element representing the state the runtime system is currently in as stored in the given exception instance.

#### See also:

`hpx::diagnostic_information()`,      `hpx::get_error_host_name()`,      `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`,      `hpx::get_error_file_name()`,      `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`,      `hpx::get_error_thread_id()`,      `hpx::get_error_backtrace()`,  
`hpx::get_error_env()`, `hpx::get_error()`, `hpx::get_error_what()`, `hpx::get_error_thread_description()`

**Parameters** `xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws** `std::bad_alloc` – (if one of the required allocations fails)

**Returns** The point runtime state at the point at which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

## hpx/runtime\_local/get\_locality\_id.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

`std::uint32_t get_locality_id(error_code &ec = throws)`

Return the number of the locality this function is being called from.

This function returns the id of the current locality.

---

**Note:** The returned value is zero based and its maximum value is smaller than the overall number of localities the current application is running on (as returned by `get_num_localities()`).

---

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

## hpx/runtime\_local/get\_locality\_name.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

`std::string get_locality_name()`

Return the name of the locality this function is called on.

This function returns the name for the locality on which this function is called.

#### See also:

`future<std::string> get_locality_name(hpx::id_type const& id)`

**Returns** This function returns the name for the locality on which the function is called. The name is retrieved from the underlying networking layer and may be different for different parcelports.

## hpx/runtime\_local/get\_num\_all\_localities.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

#### `std::uint32_t get_initial_num_localities()`

Return the number of localities which were registered at startup for the running application.

The function `get_initial_num_localities` returns the number of localities which were connected to the console at application startup.

**See also:**

`hpx::find_all_localities`, `hpx::get_num_localities`

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

#### `hpx::future<std::uint32_t> get_num_localities()`

Asynchronously return the number of localities which are currently registered for the running application.

The function `get_num_localities` asynchronously returns the number of localities currently connected to the console. The returned future represents the actual result.

**See also:**

`hpx::find_all_localities`, `hpx::get_num_localities`

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

---

#### `std::uint32_t get_num_localities(launch::sync_policy, error_code &ec = throws)`

Return the number of localities which are currently registered for the running application.

The function `get_num_localities` returns the number of localities currently connected to the console.

**See also:**

`hpx::find_all_localities`, `hpx::get_num_localities`

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

## hpx/runtime\_local/get\_os\_thread\_count.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

#### `std::size_t get_os_thread_count()`

Return the number of OS-threads running in the runtime instance the current HPX-thread is associated with.

#### `std::size_t get_os_thread_count(threads::executor const &exec)`

Return the number of worker OS- threads used by the given executor to execute HPX threads.

This function returns the number of cores used to execute HPX threads for the given executor. If the function is called while no HPX runtime system is active, it will return zero. If the executor is not valid, this function will fall back to retrieving the number of OS threads used by HPX.

**Parameters** **exec** – [in] The executor to be used.

namespace **threads**

## hpx/runtime\_local/get\_thread\_name.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

`std::string get_thread_name()`

Return the name of the calling thread.

This function returns the name of the calling thread. This name uniquely identifies the thread in the context of HPX. If the function is called while no HPX runtime system is active, the result will be “<unknown>”.

### `hpx/runtime_local/get_worker_thread_num.hpp`

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

### `hpx/runtime_local/report_error.hpp`

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

namespace `hpx`

## Functions

`void report_error(std::size_t num_thread, std::exception_ptr const &e)`

The function `report_error` reports the given exception to the console.

`void report_error(std::exception_ptr const &e)`

The function `report_error` reports the given exception to the console.

### `hpx/runtime_local/runtime_local.hpp`

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

namespace `hpx`

## Functions

`void set_error_handlers()`

class `runtime`

## Public Types

`using notification_policy_type = threads::policies::callback_notifier`

Generate a new notification policy instance for the given thread name prefix

`using hpx_main_function_type = int()`

The `hpx_main_function_type` is the default function type usable as the main HPX thread function.

```
using hpx_errorssink_function_type = void(std::uint32_t, std::string const&)
```

## Public Functions

```
virtual notification_policy_type get_notification_policy(char const *prefix,  
                                         runtime_local::os_thread_type type)
```

```
state get_state() const
```

```
void set_state(state s)
```

```
explicit runtime(hpx::util::runtime_configuration &rte, bool initialize)
```

Construct a new HPX runtime instance.

```
virtual ~runtime()
```

The destructor makes sure all HPX runtime services are properly shut down before exiting.

```
void on_exit(hpx::function<void()> const &f)
```

Manage list of functions to call on exit.

```
void starting()
```

Manage runtime ‘stopped’ state.

```
void stopping()
```

Call all registered on\_exit functions.

```
bool stopped() const
```

This accessor returns whether the runtime instance has been stopped.

```
hpx::util::runtime_configuration &get_config()
```

access configuration information

```
hpx::util::runtime_configuration const &get_config() const
```

```
std::size_t get_instance_number() const
```

```
util::thread_mapper &get_thread_mapper()
```

Return a reference to the internal PAPI thread manager.

```
threads::topology const &get_topology() const
```

```
virtual int run(hpx::function<hpx_main_function_type> const &func)
```

Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

---

**Note:** The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

---

**Parameters** **func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx\_main\_function\_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

**Returns** This function will return the value as returned as the result of the invocation of the function object given by the parameter *func*.

`virtual int run()`

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

**Returns** This function will always return 0 (zero).

`virtual void rethrow_exception()`

Rethrow any stored exception (to be called after `stop()`)

`virtual int start(hpx::function<hpx\_main\_function\_type> const &func, bool blocking = false)`

Start the runtime system.

**Parameters**

- **func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef `hpx_main_function_type`.
- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function `runtime::start` will call `runtime::wait` internally.

**Returns** If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

`virtual int start(bool blocking = false)`

Start the runtime system.

**Parameters** **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function `runtime::start` will call `runtime::wait` internally .

**Returns** If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

`virtual int wait()`

Wait for the shutdown action to be executed.

**Returns** This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

`virtual void stop(bool blocking = true)`

Initiate termination of the runtime system.

**Parameters** **blocking** – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

`virtual int suspend()`

Suspend the runtime system.

`virtual int resume()`

Resume the runtime system.

`virtual int finalize(double)`

`virtual bool is_networking_enabled()`

Return true if networking is enabled.

`virtual hpx::threads::threadmanager &get_thread_manager()`

Allow access to the thread manager instance used by the HPX runtime.

```
virtual std::string here() const  
    Returns a string of the locality endpoints (usable in debug output)
```

```
virtual bool report_error(std::size_t num_thread, std::exception_ptr const &e, bool terminate_all = true)
```

Report a non-recoverable error to the runtime system.

**Parameters**

- **num\_thread** – [in] The number of the operating system thread the error has been detected in.
- **e** – [in] This is an instance encapsulating an exception which lead to this function call.

```
virtual bool report_error(std::exception_ptr const &e, bool terminate_all = true)
```

Report a non-recoverable error to the runtime system.

---

**Note:** This function will retrieve the number of the current shepherd thread and forward to the report\_error function above.

---

**Parameters** **e** – [in] This is an instance encapsulating an exception which lead to this function call.

```
virtual void add_pre_startup_function(startup_function_type f)
```

Add a function to be executed inside a HPX thread before hpx\_main but guaranteed to be executed before any startup function registered with *add\_startup\_function*.

---

**Note:** The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

---

**Parameters** **f** – The function ‘f’ will be called from inside a HPX thread before hpx\_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

```
virtual void add_startup_function(startup_function_type f)
```

Add a function to be executed inside a HPX thread before hpx\_main

**Parameters** **f** – The function ‘f’ will be called from inside a HPX thread before hpx\_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

```
virtual void add_pre_shutdown_function(shutdown_function_type f)
```

Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

---

**Note:** The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

---

**Parameters** **f** – The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

```
virtual void add_shutdown_function(shutdown_function_type f)
```

Add a function to be executed inside a HPX thread during hpx::finalize

**Parameters** **f** – The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

---

```
virtual hpx::util::io_service_pool *get_thread_pool(char const *name)
```

Access one of the internal thread pools (io\_service instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are “main\_pool”, “io\_pool”, “parcel\_pool”, and “timer\_pool”. For any other argument value the function will return zero.

```
virtual bool register_thread(char const *name, std::size_t num = 0, bool service_thread = true,  
                           error_code &ec = throws)
```

Register an external OS-thread with HPX.

This function should be called from any OS-thread which is external to HPX (not created by HPX), but which needs to access HPX functionality, such as setting a value on a promise or similar.

‘main’, ‘io’, ‘timer’, ‘parcel’, ‘worker’

---

**Note:** The function will compose a thread name of the form ‘<name>-thread#<num>’ which is used to register the thread. It is the user’s responsibility to ensure that each (composed) thread name is unique. HPX internally uses the following names for the threads it creates, do not reuse those:

---

**Note:** This function should be called for each thread exactly once. It will fail if it is called more than once.

#### Parameters

- **name** – [in] The name to use for thread registration.
- **num** – [in] The sequence number to use for thread registration. The default for this parameter is zero.
- **service\_thread** – [in] The thread should be registered as a service thread. The default for this parameter is ‘true’. Any service threads will be pinned to cores not currently used by any of the HPX worker threads.

**Returns** This function will return whether the requested operation succeeded or not.

```
virtual bool unregister_thread()
```

Unregister an external OS-thread with HPX.

This function will unregister any external OS-thread from HPX.

---

**Note:** This function should be called for each thread exactly once. It will fail if it is called more than once. It will fail as well if the thread has not been registered before (see `register_thread`).

**Returns** This function will return whether the requested operation succeeded or not.

```
virtual runtime_local::os_thread_data get_os_thread_data(std::string const &label) const
```

Access data for a given OS thread that was previously registered by `register_thread`.

```
virtual bool enumerate_os_threads(hpx::function<bool(runtime_local::os_thread_data const&)>  
                               const &f) const
```

Enumerate all OS threads that have registered with the runtime.

```
notification_policy_type::on_startstop_type on_start_func() const
```

```
notification_policy_type::on_startstop_type on_stop_func() const
```

```
notification_policy_type::on_error_type on_error_func() const
notification_policy_type::on_startstop_type on_start_func(notification_policy_type::on_startstop_type&&)
notification_policy_type::on_startstop_type on_stop_func(notification_policy_type::on_startstop_type&&)
notification_policy_type::on_error_type on_error_func(notification_policy_type::on_error_type&&)
virtual std::uint32_t get_locality_id(error_code &ec) const
virtual std::size_t get_num_worker_threads() const
virtual std::uint32_t get_num_localities(hpx::launch::sync_policy, error_code &ec) const
virtual std::uint32_t get_initial_num_localities() const
virtual hpx::future<std::uint32_t> get_num_localities() const
virtual std::string get_locality_name() const
inline virtual std::uint32_t assign_cores(std::string const&, std::uint32_t)
inline virtual std::uint32_t assign_cores()
```

## Public Static Functions

```
static std::uint64_t get_system_uptime()
```

Return the system uptime measure on the thread executing this call.

## Protected Types

```
using on_exit_type = std::vector<hpx::function<void()>>
```

## Protected Functions

```
explicit runtime(hpx::util::runtime_configuration &rtcfg)

## Private Functions

```
void stop_helper(bool blocking, std::condition_variable &cond, std::mutex &mtx)
    Helper function to stop the runtime.
    Parameters blocking – [in] This allows to control whether this call blocks until the runtime
        system has been fully stopped. If this parameter is false then this call will initiate the stop
        action but will return immediately. Use a second call to stop with this parameter set to true
        to wait for all internal work to be completed.

void deinit_tss_helper(char const *context, std::size_t num)

void init_tss_ex(char const *context, runtime_local::os_thread_type type, std::size_t

## Functions

`char const *get_stack_size_name(std::ptrdiff_t size)`

Returns the stack size name.

Get the readable string representing the given stack size constant.

**Parameters** `size` – this represents the stack size

`std::ptrdiff_t get_default_stack_size()`

Returns the default stack size.

Get the default stack size in bytes.

`std::ptrdiff_t get_stack_size(thread_stacksize)`

Returns the stack size corresponding to the given stack size enumeration.

Get the stack size corresponding to the given stack size enumeration.

**Parameters** `size` – this represents the stack size

namespace **util**

## Functions

`bool retrieve_commandline_arguments(hpx::program_options::options_description const &app_options, hpx::program_options::variables_map &vm)`

`bool retrieve_commandline_arguments(std::string const &appname, hpx::program_options::variables_map &vm)`

## hpx/runtime\_local/runtime\_local\_fwd.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

`bool register_thread(runtime *rt, char const *name, error_code &ec = throws)`

Register the current kernel thread with HPX, this should be done once for each external OS-thread intended to invoke HPX functionality. Calling this function more than once will return false.

`void unregister_thread(runtime *rt)`

Unregister the thread from HPX, this should be done once in the end before the external thread exists.

`runtime_local::os_thread_data get_os_thread_data(std::string const &label)`

Access data for a given OS thread that was previously registered by `register_thread`. This function must be called from a thread that was previously registered with the runtime.

`bool enumerate_os_threads(hpx::function<bool(os_thread_data const&)> const &f)`

Enumerate all OS threads that have registered with the runtime.

`std::size_t get_runtime_instance_number()`

Return the runtime instance number associated with the runtime instance the current thread is running in.

`bool register_on_exit(hpx::function<void()> const&)`

Register a function to be called during system shutdown.

`bool is_starting()`

Test whether the runtime system is currently being started.

This function returns whether the runtime system is currently being started or not, e.g. whether the current state of the runtime system is `hpx::state::startup`

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

`bool tolerate_node_faults()`

Test if HPX runs in fault-tolerant mode.

This function returns whether the runtime system is running in fault-tolerant mode

`bool is_running()`

Test whether the runtime system is currently running.

This function returns whether the runtime system is currently running or not, e.g. whether the current state of the runtime system is `hpx::state::running`

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

`bool is_stopped()`

Test whether the runtime system is currently stopped.

This function returns whether the runtime system is currently stopped or not, e.g. whether the current state of the runtime system is `hpx::state::stopped`

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

`bool is_stopped_or_shutting_down()`

Test whether the runtime system is currently being shut down.

This function returns whether the runtime system is currently being shut down or not, e.g. whether the current state of the runtime system is `hpx::state::stopped` or `hpx::state::shutdown`

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

`std::size_t get_num_worker_threads()`

Return the number of worker OS- threads used to execute HPX threads.

This function returns the number of OS-threads used to execute HPX threads. If the function is called while no HPX runtime system is active, it will return zero.

`std::uint64_t get_system_uptime()`

Return the system uptime measure on the thread executing this call.

This function returns the system uptime measured in nanoseconds for the thread executing this call. If the function is called while no HPX runtime system is active, it will return zero.

namespace **threads**

## **hpx/runtime\_local/service\_executors.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parallel**

namespace **execution**

### Enums

enum class **service\_executor\_type**

*Values:*

enumerator **io\_thread\_pool**

Selects creating a service executor using the I/O pool of threads

enumerator **parcel\_thread\_pool**

Selects creating a service executor using the parcel pool of threads

enumerator **timer\_thread\_pool**

Selects creating a service executor using the timer pool of threads

enumerator **main\_thread**

Selects creating a service executor using the main thread

struct **io\_pool\_executor** : public *service\_executor*

### Public Functions

inline **io\_pool\_executor()**

struct **main\_pool\_executor** : public *service\_executor*

## Public Functions

```
inline main_pool_executor()
```

```
struct parcel_pool_executor : public service_executor
```

## Public Functions

```
inline parcel_pool_executor(char const *name_suffix = "-tcp")
```

```
struct service_executor : public service_executor
```

## Public Functions

```
inline service_executor(service_executor_type t, char const *name_suffix = "")
```

```
struct timer_pool_executor : public service_executor
```

## Public Functions

```
inline timer_pool_executor()
```

## hpx/runtime\_local/shutdown\_function.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Typedefs

```
typedef hpx::move_only_function<void()> shutdown_function_type
```

The type of a function which is registered to be executed as a shutdown or pre-shutdown function.

### Functions

```
void register_pre_shutdown_function(shutdown_function_type f)
```

Add a function to be executed by a HPX thread during *hpx::finalize()* but guaranteed before any shutdown function is executed (system-wide)

Any of the functions registered with *register\_pre\_shutdown\_function* are guaranteed to be executed by an HPX thread during the execution of *hpx::finalize()* before any of the registered shutdown functions are executed (see: *hpx::register\_shutdown\_function()*).

**See also:**

`hpx::register_shutdown_function()`

---

**Note:** If this function is called while the pre-shutdown functions are being executed, or after that point, it will raise a `invalid_status` exception.

---

**Parameters** `f` – [in] The function to be registered to run by an HPX thread as a pre-shutdown function.

`void register_shutdown_function(shutdown_function_type f)`

Add a function to be executed by a HPX thread during `hpx::finalize()` but guaranteed after any pre-shutdown function is executed (system-wide)

Any of the functions registered with `register_shutdown_function` are guaranteed to be executed by an HPX thread during the execution of `hpx::finalize()` after any of the registered pre-shutdown functions are executed (see: `hpx::register_pre_shutdown_function()`).

**See also:**

`hpx::register_pre_shutdown_function()`

---

**Note:** If this function is called while the shutdown functions are being executed, or after that point, it will raise a `invalid_status` exception.

---

**Parameters** `f` – [in] The function to be registered to run by an HPX thread as a shutdown function.

## hpx/runtime\_local/startup\_function.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### TypeDefs

`typedef hpx::move_only_function<void()> startup_function_type`

The type of a function which is registered to be executed as a startup or pre-startup function.

## Functions

```
void register_pre_startup_function(startup_function_type f)
```

Add a function to be executed by a HPX thread before `hpx_main` but guaranteed before any startup function is executed (system-wide).

Any of the functions registered with `register_pre_startup_function` are guaranteed to be executed by an HPX thread before any of the registered startup functions are executed (see [hpx::register\\_startup\\_function\(\)](#)).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

### See also:

[hpx::register\\_startup\\_function\(\)](#)

---

**Note:** If this function is called while the pre-startup functions are being executed or after that point, it will raise a `invalid_status` exception.

---

**Parameters** **f** – [in] The function to be registered to run by an HPX thread as a pre-startup function.

```
void register_startup_function(startup_function_type f)
```

Add a function to be executed by a HPX thread before `hpx_main` but guaranteed after any pre-startup function is executed (system-wide).

Any of the functions registered with `register_startup_function` are guaranteed to be executed by an HPX thread after any of the registered pre-startup functions are executed (see: [hpx::register\\_pre\\_startup\\_function\(\)](#), but before `hpx_main` is being called).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

### See also:

[hpx::register\\_pre\\_startup\\_function\(\)](#)

---

**Note:** If this function is called while the startup functions are being executed or after that point, it will raise a `invalid_status` exception.

---

**Parameters** **f** – [in] The function to be registered to run by an HPX thread as a startup function.

## hpx/runtime\_local/thread\_hooks.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

*threads::policies::callback\_notifier::on\_startstop\_type* **get\_thread\_on\_start\_func()**

Retrieve the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *register\_thread\_on\_start\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Returns** The currently installed error handler function.

*threads::policies::callback\_notifier::on\_startstop\_type* **get\_thread\_on\_stop\_func()**

Retrieve the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *register\_thread\_on\_stop\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Returns** The currently installed error handler function.

*threads::policies::callback\_notifier::on\_error\_type* **get\_thread\_on\_error\_func()**

Retrieve the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *register\_thread\_on\_error\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Returns** The currently installed error handler function.

*threads::policies::callback\_notifier::on\_startstop\_type* **register\_thread\_on\_start\_func**(*threads::policies::callback\_notifier*:&&f)

Set the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *get\_thread\_on\_start\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Parameters** **f** – The function to install as the new start handler.

**Returns** The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

`threads::policies::callback_notifier::on_startstop_type register_thread_on_stop_func(threads::policies::callback_notifier::on_startstop_type& &f)`

Set the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see `get_thread_on_stop_func`).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Parameters** **f** – The function to install as the new stop handler.

**Returns** The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

`threads::policies::callback_notifier::on_error_type register_thread_on_error_func(threads::policies::callback_notifier::on_error_type& &f)`

Set the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see `get_thread_on_error_func`).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Parameters** **f** – The function to install as the new error handler.

**Returns** The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

## [hpx/runtime\\_local/thread\\_pool\\_helpers.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resource**

## Functions

`std::size_t get_num_thread_pools()`

Return the number of thread pools currently managed by the *resource\_partitioner*

`std::size_t get_num_threads()`

Return the number of threads in all thread pools currently managed by the *resource\_partitioner*

`std::size_t get_num_threads(std::string const &pool_name)`

Return the number of threads in the given thread pool currently managed by the *resource\_partitioner*

`std::size_t get_num_threads(std::size_t pool_index)`

Return the number of threads in the given thread pool currently managed by the *resource\_partitioner*

`std::size_t get_pool_index(std::string const &pool_name)`

Return the internal index of the pool given its name.

`std::string const &get_pool_name(std::size_t pool_index)`

Return the name of the pool given its internal index.

`threads::thread_pool_base &get_thread_pool(std::string const &pool_name)`

Return the name of the pool given its name.

`threads::thread_pool_base &get_thread_pool(std::size_t pool_index)`

Return the thread pool given its internal index.

`bool pool_exists(std::string const &pool_name)`

Return true if the pool with the given name exists.

`bool pool_exists(std::size_t pool_index)`

Return true if the pool with the given index exists.

namespace **threads**

## Functions

`std::int64_t get_thread_count(thread_schedule_state state = thread_schedule_state::unknown)`

The function *get\_thread\_count* returns the number of currently known threads.

---

**Note:** If state == unknown this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

**Parameters** **state** – [in] This specifies the thread-state for which the number of threads should be retrieved.

`std::int64_t get_thread_count(thread_priority priority, thread_schedule_state state = thread_schedule_state::unknown)`

The function *get\_thread\_count* returns the number of currently known threads.

---

**Note:** If state == unknown this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

**Parameters**

- **priority** – [in] This specifies the thread-priority for which the number of threads should be retrieved.
- **state** – [in] This specifies the thread-state for which the number of threads should be retrieved.

`std::int64_t get_idle_core_count()`

The function `get_idle_core_count` returns the number of currently idling threads (cores).

`mask_type get_idle_core_mask()`

The function `get_idle_core_mask` returns a bit-mask representing the currently idling threads (cores).

`bool enumerate_threads(hpx::function<bool(thread_id_type)> const &f, thread_schedule_state state = thread_schedule_state::unknown)`

The function `enumerate_threads` will invoke the given function `f` for each thread with a matching thread state.

**Parameters**

- **f** – [in] The function which should be called for each matching thread. Returning ‘false’ from this function will stop the enumeration process.
- **state** – [in] This specifies the thread-state for which the threads should be enumerated.

## synchronization

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### **hpx/synchronization/barrier.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

```
template<typename OnCompletion = detail::empty_oncompletion>
```

```
class barrier
```

*#include <barrier.hpp>* A barrier is a thread coordination mechanism whose lifetime consists of a sequence of barrier phases, where each phase allows at most an expected number of threads to block until the expected number of threads arrive at the barrier. [ Note: A barrier is useful for managing repeated tasks that are handled by multiple threads. - end note ] Each barrier phase consists of the following steps:

- The expected count is decremented by each call to `arrive` or `arrive_and_drop`.
- When the expected count reaches zero, the phase completion step is run. For the specialization with the default value of the `CompletionFunction` template parameter, the completion step is run as part of the call to `arrive` or `arrive_and_drop` that caused the expected count to reach zero. For other specializations, the completion step is run on one of the threads that arrived at the barrier during the phase.
- When the completion step finishes, the expected count is reset to what was specified by the `expected` argument to the constructor, possibly adjusted by calls to `arrive_and_drop`, and the next phase starts.

Each phase defines a phase synchronization point. Threads that arrive at the barrier during the phase can block on the phase synchronization point by calling `wait`, and will remain blocked until the phase completion step is run. The phase completion step that is executed at the end of each phase has the following effects:

- Invokes the completion function, equivalent to `completion()`.
- Unblocks all threads that are blocked on the phase synchronization point.

The end of the completion step strongly happens before the returns from all calls that were unblocked by the completion step. For specializations that do not have the default value of the CompletionFunction template parameter, the behavior is undefined if any of the barrier object's member functions other than wait are called while the completion step is in progress.

Concurrent invocations of the member functions of barrier, other than its destructor, do not introduce data races. The member functions arrive and arrive\_and\_drop execute atomically.

CompletionFunction shall meet the Cpp17MoveConstructible (Table 28) and Cpp17Destructible (Table 32) requirements. std::is\_nothrow\_invocable\_v<CompletionFunction&> shall be true.

The default value of the CompletionFunction template parameter is an unspecified type, such that, in addition to satisfying the requirements of CompletionFunction, it meets the Cpp17DefaultConstructible requirements (Table 27) and completion() has no effects.

barrier::arrival\_token is an unspecified type, such that it meets the Cpp17MoveConstructible (Table 28), Cpp17MoveAssignable (Table 30), and Cpp17Destructible (Table 32) requirements.

## Public Types

```
using arrival_token = bool
```

## Public Functions

inline explicit constexpr barrier(*std::ptrdiff\_t* expected, *OnCompletion* completion = *OnCompletion*())

Preconditions: expected >= 0 is true and expected <= max() is true.

Effects: Sets both the initial expected count for each barrier phase and the current expected count for the first phase to expected. Initializes completion with std::move(f). Starts the first phase. [Note: If expected is 0 this object can only be destroyed.- end note]

### Throws

inline *arrival\_token* arrive(*std::ptrdiff\_t* update = 1)

Preconditions: update > 0 is true, and update is less than or equal to the expected count for the current barrier phase.

Effects: Constructs an object of type arrival\_token that is associated with the phase synchronization point for the current phase. Then, decrements the expected count by update.

Synchronization: The call to arrive strongly happens before the start of the phase completion step for the current phase.

### Throws

Returns : The constructed arrival\_token object.

inline void wait(*arrival\_token* &&old\_phase) const

Preconditions: arrival is associated with the phase synchronization point for the current phase or the immediately preceding phase of the same barrier object.

Effects: Blocks at the synchronization point associated with HPX\_MOVE(arrival) until the phase completion step of the synchronization point's phase is run. [ Note: If arrival is associated with the synchronization point for a previous phase, the call returns immediately. - end note ]

### Throws

inline void arrive\_and\_wait()

Effects: Equivalent to: wait(arrive()).

```
inline void arrive_and_drop()
```

Preconditions: The expected count for the current barrier phase is greater than zero.

Effects: Decrements the initial expected count for all subsequent phases by one. Then decrements the expected count for the current phase by one.

Synchronization: The call to `arrive_and_drop` strongly happens before the start of the phase completion step for the current phase.

**Throws**

## **hpx/synchronization/latch.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

```
class latch
```

```
#include <latch.hpp> Latches are a thread coordination mechanism that allow one or more threads to  
block until an operation is completed. An individual latch is a singleuse object; once the operation has  
been completed, the latch cannot be reused.
```

Subclassed by *hpx*::*lcos*::*local*::*latch*

## Public Functions

**HPX\_NON\_COPYABLE(*latch*)**

inline explicit **latch**(*std*::ptrdiff\_t count)

Initialize the latch

Requires: count  $\geq 0$ . Synchronization: None Postconditions: counter\_ == count.

**~latch()** = default

Requires: No threads are blocked at the synchronization point.

---

**Note:** May be called even if some threads have not yet returned from [wait\(\)](#) or [count\\_down\\_and\\_wait\(\)](#), provided that counter\_ is 0.

---

**Note:** The destructor might not return until all threads have exited [wait\(\)](#) or [count\\_down\\_and\\_wait\(\)](#).

---

---

**Note:** It is the caller's responsibility to ensure that no other thread enters [wait\(\)](#) after one thread has called the destructor. This may require additional coordination.

---

inline void **count\_down**(*std*::ptrdiff\_t update)

Decrements counter\_ by n. Does not block.

Requires: counter\_  $\geq n$  and  $n \geq 0$ .

Synchronization: Synchronizes with all calls that block on this latch and with all [try\\_wait](#) calls on this latch that return true .

**Throws Nothing.** –

inline bool **try\_wait**() const noexcept

Returns: With very low probability false. Otherwise counter == 0.

inline void **wait**() const

If counter\_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter\_ reaches 0.

**Throws Nothing.** –

inline void **arrive\_and\_wait**(*std*::ptrdiff\_t update = 1)

Effects: Equivalent to: [count\\_down](#)(update); [wait\(\)](#);

## Public Static Functions

**static inline constexpr std::ptrdiff\_t() max () noexcept**

Returns: The maximum value of counter that the implementation supports.

## Protected Types

```
using mutex_type = hpx::spinlock
```

## Protected Attributes

```
mutable util::cache_line_data<mutex_type> mtx_
```

```
mutable util::cache_line_data<hpx::lcos::local::detail::condition_variable> cond_
```

```
std::atomic<std::ptrdiff_t> counter_
```

```
bool notified_
```

```
namespace lcos
```

```
namespace local
```

```
class latch : public hpx::latch
```

#include <latch.hpp> A latch maintains an internal counter\_ that is initialized when the latch is created. Threads may block at a synchronization point waiting for counter\_ to be decremented to 0. When counter\_ reaches 0, all such blocked threads are released.

Calls to `countdown_and_wait()`, `count_down()`, `wait()`, `is_ready()`, `count_up()`, and `reset()` behave as atomic operations.

---

**Note:** A `hpx::latch` is not an LCO in the sense that it has no global id and it can't be triggered using the action (parcel) mechanism. Use `hpx::distributed::latch` instead if this is required. It is just a low level synchronization primitive allowing to synchronize a given number of *threads*.

---

## Public Functions

```
HPX_NON_COPYABLE(latch)
```

```
inline explicit latch(std::ptrdiff_t count)
```

Initialize the latch

Requires: `count >= 0`. Synchronization: None Postconditions: `counter_ == count`.

```
~latch() = default
```

Requires: No threads are blocked at the synchronization point.

---

**Note:** May be called even if some threads have not yet returned from `wait()` or `count_down_and_wait()`, provided that `counter_` is 0.

---

---

**Note:** The destructor might not return until all threads have exited `wait()` or `count_down_and_wait()`.

---

---

**Note:** It is the caller's responsibility to ensure that no other thread enters `wait()` after one thread has called the destructor. This may require additional coordination.

---

inline void **count\_down\_and\_wait()**

Decrements counter\_ by 1 . Blocks at the synchronization point until counter\_ reaches 0.

Requires: counter\_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all `is_ready` calls on this latch that return true.

**Throws** Nothing. –

inline bool **is\_ready()** const noexcept

Returns: counter\_ == 0. Does not block.

**Throws** Nothing. –

inline void **abort\_all()**

inline void **count\_up(*std*::ptrdiff\_t n)**

Increments counter\_ by n. Does not block.

Requires: n >= 0.

**Throws** Nothing. –

inline void **reset(*std*::ptrdiff\_t n)**

Reset counter\_ to n. Does not block.

Requires: n >= 0.

**Throws** Nothing. –

inline bool **reset\_if\_needed\_and\_count\_up(*std*::ptrdiff\_t n, *std*::ptrdiff\_t count)**

Effects: Equivalent to: if (`is_ready()`) `reset(count); count_up(n);` Returns: true if the latch was reset

## hpx/synchronization/recursive\_mutex.hpp

namespace **hpx**

## TypeDefs

```
using recursive_mutex = detail::recursive_mutex_impl<>
```

```
namespace lcos
```

```
    namespace local
```

## TypeDefs

```
typedef hpx::recursive_mutex instead
```

## [hpx/synchronization/sliding\\_semaphore.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

## TypeDefs

```
using sliding_semaphore = sliding_semaphore_var<>
```

```
template<typename Mutex = hpx::spinlock>
```

```
class sliding_semaphore_var
```

```
#include <sliding_semaphore.hpp> A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.
```

Sliding semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. The difference to a counting semaphore is that a sliding semaphore will not limit the number of threads which are allowed to proceed, but will make sure that the difference between the (arbitrary) number passed to set and wait does not exceed a given threshold.

## Public Functions

inline **sliding\_semaphore\_var**(*std*::int64\_t max\_difference, *std*::int64\_t lower\_limit = 0)

Construct a new sliding semaphore.

**Parameters**

- **max\_difference** – [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- **lower\_limit** – [in] The initial lower limit.

inline void **set\_max\_difference**(*std*::int64\_t max\_difference, *std*::int64\_t lower\_limit = 0)

Set/Change the difference that will cause the semaphore to trigger.

**Parameters**

- **max\_difference** – [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- **lower\_limit** – [in] The initial lower limit.

inline void **wait**(*std*::int64\_t upper\_limit)

Wait for the semaphore to be signaled.

**Parameters** **upper\_limit** – [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower\_limit which was set by *signal()* is larger than the max\_difference.

inline bool **try\_wait**(*std*::int64\_t upper\_limit = 1)

Try to wait for the semaphore to be signaled.

**Parameters** **upper\_limit** – [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower\_limit which was set by *signal()* is larger than the max\_difference.

**Returns** The function returns true if the calling thread would not block if it was calling *wait()*.

inline void **signal**(*std*::int64\_t lower\_limit)

Signal the semaphore.

**Parameters** **lower\_limit** – [in] The new lower limit. This will update the current lower limit of this semaphore. It will also re-schedule all suspended threads for which their associated upper limit is not larger than the lower limit plus the max\_difference.

inline *std*::int64\_t **signal\_all**()

namespace **hpx**

namespace **threads**

#### Functions

`hpx::future<void> resume_processing_unit(thread_pool_base &pool, std::size_t virt_core)`

Resumes the given processing unit. When the processing unit has been resumed the returned future will be ready.

---

**Note:** Can only be called from an HPX thread. Use `resume_processing_unit_cb` or to resume the processing unit from outside HPX. Requires that the pool has `threads::policies::enable_elasticity` set.

---

**Parameters** `virt_core` – [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

**Returns** A `future<void>` which is ready when the given processing unit has been resumed.

`void resume_processing_unit_cb(thread_pool_base &pool, hpx::function<void(void)> callback, std::size_t virt_core, error_code &ec = throws)`

Resumes the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been resumed.

---

**Note:** Requires that the pool has `threads::policies::enable_elasticity` set.

---

#### Parameters

- `callback` – [in] Callback which is called when the processing unit has been suspended.
- `virt_core` – [in] The processing unit to resume.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`hpx::future<void> suspend_processing_unit(thread_pool_base &pool, std::size_t virt_core)`

Suspends the given processing unit. When the processing unit has been suspended the returned future will be ready.

---

**Note:** Can only be called from an HPX thread. Use `suspend_processing_unit_cb` or to suspend the processing unit from outside HPX. Requires that the pool has `threads::policies::enable_elasticity` set.

---

**Parameters** `virt_core` – [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

**Throws** `hpx::exception` – if called from outside the HPX runtime.

**Returns** A future<void> which is ready when the given processing unit has been suspended.

```
void suspend_processing_unit_cb(hpx::function<void(void)> callback, thread_pool_base &pool,  
                                std::size_t virt_core, error_code &ec = throws)
```

Suspends the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been suspended.

**Note:** Requires that the pool has `threads::policies::enable_elasticity` set.

#### Parameters

- `callback` – [in] Callback which is called when the processing unit has been suspended.
- `virt_core` – [in] The processing unit to suspend.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```
hpx::future<void> resume_pool(thread_pool_base &pool)
```

Resumes the thread pool. When the all OS threads on the thread pool have been resumed the returned future will be ready.

**Note:** Can only be called from an HPX thread. Use `resume_cb` or `resume_direct` to suspend the pool from outside HPX.

**Throws** `hpx::exception` – if called from outside the HPX runtime.

**Returns** A future<void> which is ready when the thread pool has been resumed.

```
void resume_pool_cb(thread_pool_base &pool, hpx::function<void(void)> callback, error_code &ec =  
                           throws)
```

Resumes the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been resumed.

#### Parameters

- `callback` – [in] called when the thread pool has been resumed.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```
hpx::future<void> suspend_pool(thread_pool_base &pool)
```

Suspends the thread pool. When the all OS threads on the thread pool have been suspended the returned future will be ready.

**Note:** Can only be called from an HPX thread. Use `suspend_cb` or `suspend_direct` to suspend the pool from outside HPX. A thread pool cannot be suspended from an HPX thread running on the pool itself.

**Throws** `hpx::exception` – if called from outside the HPX runtime.

**Returns** A future<void> which is ready when the thread pool has been suspended.

```
void suspend_pool_cb(thread_pool_base &pool, hpx::function<void(void)> callback, error_code &ec  
                           = throws)
```

Suspends the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been suspended.

---

**Note:** A thread pool cannot be suspended from an HPX thread running on the pool itself.

---

#### Parameters

- **callback** – [in] called when the thread pool has been suspended.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Throws** `hpx::exception` – if called from an HPX thread which is running on the pool itself.

## threading\_base

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/threading\_base/annotated\_function.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Functions

```
template<typename F>
constexpr F &&annotated_function(F &&f, char const* = nullptr) noexcept
```

Returns a function annotated with the given annotation.

Annotating includes setting the thread description per thread id.

#### Parameters **function** –

```
template<typename F>
constexpr F &&annotated_function(F &&f, std::string const&) noexcept
```

namespace **traits**

namespace **util**

#### Functions

```

## hpx/threading\_base/register\_thread.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **threads**

### Functions

```
template<typename F>
thread_function_type make_thread_function(F &&f)

template<typename F>
thread_function_type make_thread_function_nullary(F &&f)

inline threads::thread_id_ref_type register_thread(threads::thread_init_data &data,
                                                 threads::thread_pool_base *pool, error_code
                                                 &ec = throws)
```

Create a new *thread* using the given data.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **data** – [in] The data to use for creating the thread.
- **pool** – [in] The thread pool to use for launching the work.
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws** *invalid\_status* – if the runtime system has not been started yet.

**Returns** This function will return the internal id of the newly created HPX-thread.

```
inline threads::thread_id_ref_type register_thread(threads::thread_init_data &data, error_code &ec
                                              = throws)
```

Create a new *thread* using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **data** – [in] The data to use for creating the thread.
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws** *invalid\_status* – if the runtime system has not been started yet.

**Returns** This function will return the internal id of the newly created HPX-thread.

```
inline thread_id_ref_type register_work(threads::thread_init_data &data, threads::thread_pool_base*pool, error_code &ec = throws)
```

Create a new work item using the given data.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **data** – [in] The data to use for creating the thread.
- **pool** – [in] The thread pool to use for launching the work.
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws** *invalid\_status* – if the runtime system has not been started yet.

```
inline thread_id_ref_type register_work(threads::thread_init_data &data, error_code &ec = throws)
```

Create a new work item using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **data** – [in] The data to use for creating the thread.
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws** *invalid\_status* – if the runtime system has not been started yet.

## hpx/threading\_base/thread\_data.hpp

See *Public API* for a list of names and headers that are part of the public *HPX API*.

namespace **hpx**

namespace **threads**

### Functions

```
thread_data *get_self_id_data()
```

The function *get\_self\_id\_data* returns the data of the HPX thread id associated with the current thread (or nullptr if the current thread is not a HPX thread).

```
thread_data *get_thread_id_data(thread_id_ref_type const &tid)
```

```
thread_data *get_thread_id_data(thread_id_type const &tid)
```

```
thread_self &get_self()
```

The function *get\_self* returns a reference to the (OS thread specific) self reference to the current HPX thread.

---

`thread_self *get_self_ptr()`

The function `get_self_ptr` returns a pointer to the (OS thread specific) self reference to the current HPX thread.

`thread_self_impl_type *get_ctx_ptr()`

The function `get_ctx_ptr` returns a pointer to the internal data associated with each coroutine.

`thread_self *get_self_ptr_checked(error_code &ec = throws)`

The function `get_self_ptr_checked` returns a pointer to the (OS thread specific) self reference to the current HPX thread.

`thread_id_type get_self_id()`

The function `get_self_id` returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

`thread_id_type get_parent_id()`

The function `get_parent_id` returns the HPX thread id of the current thread's parent (or zero if the current thread is not a HPX thread).

---

**Note:** This function will return a meaningful value only if the code was compiled with `HPX_HAVE_THREAD_PARENT_REFERENCE` being defined.

`std::size_t get_parent_phase()`

The function `get_parent_phase` returns the HPX phase of the current thread's parent (or zero if the current thread is not a HPX thread).

---

**Note:** This function will return a meaningful value only if the code was compiled with `HPX_HAVE_THREAD_PARENT_REFERENCE` being defined.

`std::ptrdiff_t get_self_stacksize()`

The function `get_self_stacksize` returns the stack size of the current thread (or zero if the current thread is not a HPX thread).

`thread_stacksize get_self_stacksize_enum()`

The function `get_self_stacksize_enum` returns the stack size of the /.

`std::uint32_t get_parent_locality_id()`

The function `get_parent_locality_id` returns the id of the locality of the current thread's parent (or zero if the current thread is not a HPX thread).

---

**Note:** This function will return a meaningful value only if the code was compiled with `HPX_HAVE_THREAD_PARENT_REFERENCE` being defined.

`std::uint64_t get_self_component_id()`

The function `get_self_component_id` returns the lva of the component the current thread is acting on

---

**Note:** This function will return a meaningful value only if the code was compiled with `HPX_HAVE_THREAD_TARGET_ADDRESS` being defined.

```
class thread_data : public thread_data_reference_counting
```

`#include <thread_data.hpp>` A *thread* is the representation of a ParalleX thread. It's a first class object in ParalleX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the *thread-manager*.

A *thread* encapsulates:

- A thread status word (see the functions `thread::get_state` and `thread::set_state`)
- A function to execute (the `thread` function)
- A frame (in this implementation this is a block of memory used as the threads stack)
- A block of registers (not implemented yet)

Generally, *threads* are not created or executed directly. All functionality related to the management of *threads* is implemented by the *thread-manager*.

## Public Types

```
using spinlock_pool = util::spinlock_pool<thread_data>
```

## Public Functions

```
thread_data(thread_data const&) = delete
```

```
thread_data(thread_data&&) = delete
```

```
thread_data &operator=(thread_data const&) = delete
```

```
thread_data &operator=(thread_data&&) = delete
```

```
inline thread_state get_state(std::memory_order order = std::memory_order_acquire) const  
noexcept
```

The `get_state` function queries the state of this thread instance.

---

**Note:** This function will be seldom used directly. Most of the time the state of a thread will be retrieved by using the function `threadmanager::get_state`.

---

**Returns** This function returns the current state of this thread. It will return one of the values as defined by the `thread_state` enumeration.

```
inline thread_state set_state(thread_schedule_state state, thread_restart_state state_ex =  
  thread_restart_state::unknown, std::memory_order load_order =  
  std::memory_order_acquire, std::memory_order exchange_order =  
  std::memory_order_seq_cst) noexcept
```

The `set_state` function changes the state of this thread instance.

---

**Note:** This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the `threadmanager`. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status `threadmanager::set_state` should be used.

---

**Parameters** `newstate` – [in] The new state to be set for the thread.

```
inline bool set_state_tagged(thread_schedule_state newstate, thread_state &prev_state,
                           thread_state &new_tagged_state, std::memory_order
                           exchange_order = std::memory_order_seq_cst) noexcept

inline bool restore_state(thread_state new_state, thread_state old_state, std::memory_order
                           load_order = std::memory_order_relaxed, std::memory_order
                           load_exchange = std::memory_order_seq_cst) noexcept
```

The restore\_state function changes the state of this thread instance depending on its current state. It will change the state atomically only if the current state is still the same as passed as the second parameter. Otherwise it won't touch the thread state of this instance.

---

**Note:** This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status *threadmanager*::*set\_state* should be used.

---

#### Parameters

- **newstate** – [in] The new state to be set for the thread.
- **oldstate** – [in] The old state of the thread which still has to be the current state.

**Returns** This function returns *true* if the state has been changed successfully

```
inline bool restore_state(thread_schedule_state new_state, thread_restart_state state_ex,
                           thread_state old_state, std::memory_order load_exchange =
                           std::memory_order_seq_cst) noexcept
```

inline constexpr *std*::uint64\_t **get\_component\_id**() const noexcept

Return the id of the component this thread is running in.

inline *util*::*thread\_description* **get\_description**() const

inline *util*::*thread\_description* **set\_description**(*util*::*thread\_description*)

inline *util*::*thread\_description* **get\_lco\_description**() const

inline *util*::*thread\_description* **set\_lco\_description**(*util*::*thread\_description*)

inline constexpr *std*::uint32\_t **get\_parent\_locality\_id**() const noexcept

Return the locality of the parent thread.

inline constexpr *thread\_id\_type* **get\_parent\_thread\_id**() const noexcept

Return the thread id of the parent thread.

inline constexpr *std*::size\_t **get\_parent\_thread\_phase**() const noexcept

Return the phase of the parent thread.

inline constexpr *util*::backtrace const \* **get\_backtrace**() const noexcept

inline *util*::backtrace const \* **set\_backtrace**(*util*::backtrace const\*) noexcept

inline constexpr *thread\_priority* **get\_priority**() const noexcept

void run_thread_exit_callbacks()
void free_thread_exit_callbacks()

inline bool is_stackless() const noexcept
void destroy_thread() override
inline policies::scheduler_base *get_scheduler_base() const noexcept
inline std::size_t get_last_worker_thread_num() const noexcept
inline void set_last_worker_thread_num(std::size_t last_worker_thread_num) noexcept
inline std::ptrdiff_t get_stack_size() const noexcept
inline thread_stacksize get_stack_size_enum() const noexcept
template<typename ThreadQueue>
inline ThreadQueue &get_queue() noexcept
inline coroutine_type::result_type operator()(hpx::execution_base::this_thread::detail::agent_storage
*agent_storage)

Execute the thread function.
Returns This function returns the thread state the thread should be scheduled from this point
on. The thread manager will use the returned value to set the thread's scheduling status.

inline virtual thread_id_type get_thread_id() const
inline virtual std::size_t get_thread_phase() const noexcept
virtual std::size_t get_thread_data() const = 0
virtual std::size_t set_thread_data(std::size_t data) = 0

false, thread_id_addr addref = thread_id_addr::yes)
virtual ~thread_data() override
virtual void destroy() noexcept = 0
```

## Protected Functions

inline *thread\_restart\_state* **set\_state\_ex**(*thread\_restart\_state* new\_state) noexcept  
The set\_state function changes the extended state of this thread instance.

---

**Note:** This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager.

---

**Parameters** **newstate** – [in] The new extended state to be set for the thread.

void **rebind\_base**(*thread\_init\_data* &*init\_data*)

## namespace **hpx**

## namespace **threads**

## Functions

`util::thread_description get_thread_description(thread_id_type const &id, error_code &ec = throws)`

The function `get_thread_description` is part of the thread related API allows to query the description of one of the threads known to the thread-manager.

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

## Parameters

- **id** – [in] The thread id of the thread being queried.
  - **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function returns the description of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the string “<unknown>”.

```
util::thread_description set_thread_description(thread_id_type const &id, util::thread_description  
  const &desc = util::thread_description(),  
  error_code &ec = throws)
```

*util::thread\_description* **get\_thread\_lco\_description**(*thread\_id\_type const &id, error\_code &ec = throws*)

```
util::thread_description set_thread_lco_description(thread_id_type const &id,  
                                         util::thread_description const &desc =  
                                         util::thread_description(), error_code &ec =  
                                         throws)

namespace **hpx**

namespace **this\_thread**

## Functions

```
threads::thread_restart_state suspend(threads::thread_schedule_state state, threads::thread_id_type id,
                                      util::thread_description const &description =
                                      util::thread_description("this_thread::suspend"), error_code &ec
                                      = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If `-&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

```
inline threads::thread_restart_state suspend(threads::thread_schedule_state state =
                                             threads::thread_schedule_state::pending,
                                             util::thread_description const &description =
                                             util::thread_description("this_thread::suspend"),
                                             error_code &ec = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If `-&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

```
threads::thread_restart_state suspend(hpx::chrono::steady_time_point const &abs_time,
                                       threads::thread_id_type id, util::thread_description const
                                       &description = util::thread_description("this_thread::suspend"),
                                       error_code &ec = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If `-&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

```
inline threads::thread_restart_state suspend(hpx::chrono::steady_time_point const &abs_time,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

```
inline threads::thread_restart_state suspend(hpx::chrono::steady_duration const &rel_time,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

```
inline threads::thread_restart_state suspend(hpx::chrono::steady_duration const &rel_time,
threads::thread_id_type const &id, util::thread_description
const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

```
inline threads::thread_restart_state suspend(std::uint64_t ms, util::thread_description const  
&description =  
util::thread_description("this_thread::suspend"),  
error_code &ec = throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given time (specified in milliseconds).

---

**Note:** Must be called from within a HPX-thread.

---

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

```
threads::thread_pool_base *get_pool(error_code &ec = throws)
```

Returns a pointer to the pool that was used to run the current thread

**Throws** If – &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

&ec = throws)
```

Set the thread state of the *thread* referenced by the *thread\_id id*.

---

**Note:** If the thread referenced by the parameter *id* is in *thread\_state::active* state this function schedules a new thread which will set the state of the thread as soon as its not active anymore. The function returns *thread\_state::active* in this case.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

### Parameters

- **id** – [in] The thread id of the thread the state should be modified for.
- **state** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **stateex** – [in] The new extended state to be set for the thread referenced by the *id* parameter.

- **priority** –
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function returns the previous state of the thread referenced by the `id` parameter. It will return one of the values as defined by the `thread_state` enumeration. If the thread is not known to the thread-manager the return value will be `thread_state::unknown`.

```
thread_id_ref_type set_thread_state(thread_id_type const &id, hpx::chrono::steady_time_point
                                    const &abs_time, std::atomic<bool> *started,
                                    thread_schedule_state state = thread_schedule_state::pending,
                                    thread_restart_state stateex = thread_restart_state::timeout,
                                    thread_priority priority = thread_priority::normal, bool
                                    retry_on_active = true, error_code &ec = throws)
```

Set the thread state of the `thread` referenced by the `thread_id id`.

Set a timer to set the state of the given `thread` to the given new value after it expired (at the given time)

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

#### Parameters

- **id** – [in] The thread id of the thread the state should be modified for.
- **abs\_time** – [in] Absolute point in time for the new thread to be run
- **started** – [in,out] A helper variable allowing to track the state of the timer helper thread
- **state** – [in] The new state to be set for the thread referenced by the `id` parameter.
- **stateex** – [in] The new extended state to be set for the thread referenced by the `id` parameter.
- **priority** –
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

#### Returns

```
inline thread_id_ref_type set_thread_state(thread_id_type const &id,
                                         hpx::chrono::steady_time_point const &abs_time,
                                         thread_schedule_state state =
                                         thread_schedule_state::pending, thread_restart_state
                                         stateex = thread_restart_state::timeout, thread_priority
                                         priority = thread_priority::normal, bool retry_on_active
                                         = true, error_code& = throws)
```

```
inline thread_id_ref_type set_thread_state(thread_id_type const &id, hpx::chrono::steady_duration
                                         const &rel_time, thread_schedule_state state =
                                         thread_schedule_state::pending, thread_restart_state
                                         stateex = thread_restart_state::timeout, thread_priority
                                         priority = thread_priority::normal, bool retry_on_active
                                         = true, error_code &ec = throws)
```

Set the thread state of the `thread` referenced by the `thread_id id`.

Set a timer to set the state of the given `thread` to the given new value after it expired (after the given duration)

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Parameters**

- **id** – [in] The thread id of the thread the state should be modified for.
- **rel\_time** – [in] Time duration after which the new thread should be run
- **state** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **stateex** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **priority** –
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

```
thread_state get_thread_state(thread_id_type const &id, error_code &ec = throws)
```

The function `get_thread_backtrace` is part of the thread related API allows to query the currently stored thread back trace (which is captured during thread suspension).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*. The function `get_thread_state` is part of the thread related API. It queries the state of one of the threads known to the thread-manager.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters**

- **id** – [in] The thread id of the thread being queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.
- **id** – [in] The thread id of the thread the state should be modified for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns the currently captured stack back trace of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the zero.

**Returns** This function returns the thread state of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be *terminated*.

```
std::size_t get_thread_phase(thread_id_type const &id, error_code &ec = throws)
```

The function `get_thread_phase` is part of the thread related API. It queries the phase of one of the threads known to the thread-manager.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters**

- **id** – [in] The thread id of the thread the phase should be modified for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns the thread phase of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be ~0.

---

`bool get_thread_interruption_enabled(thread_id_type const &id, error_code &ec = throws)`

Returns whether the given thread can be interrupted at this point.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

#### Parameters

- **id** – [in] The thread id of the thread which should be queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function returns `true` if the given thread can be interrupted at this point in time. It will return `false` otherwise.

`bool set_thread_interruption_enabled(thread_id_type const &id, bool enable, error_code &ec = throws)`

Set whether the given thread can be interrupted at this point.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

#### Parameters

- **id** – [in] The thread id of the thread which should receive the new value.
- **enable** – [in] This value will determine the new interruption enabled status for the given thread.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function returns the previous value of whether the given thread could have been interrupted.

`bool get_thread_interruption_requested(thread_id_type const &id, error_code &ec = throws)`

Returns whether the given thread has been flagged for interruption.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

#### Parameters

- **id** – [in] The thread id of the thread which should be queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function returns `true` if the given thread was flagged for interruption. It will return `false` otherwise.

`void interrupt_thread(thread_id_type const &id, bool flag, error_code &ec = throws)`

Flag the given thread for interruption.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

#### Parameters

- **id** – [in] The thread id of the thread which should be interrupted.

- **flag** – [in] The flag encodes whether the thread should be interrupted (if it is *true*), or ‘uninterrupted’ (if it is *false*).
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline void **interrupt\_thread**(thread\_id\_type const &id, *error\_code* &ec = *throws*)

void **interruption\_point**(thread\_id\_type const &id, *error\_code* &ec = *throws*)

Interrupt the current thread at this point if it was canceled. This will throw a *thread\_interrupted* exception, which will cancel the thread.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn’t throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread which should be interrupted.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

*threads::thread\_priority* **get\_thread\_priority**(thread\_id\_type const &id, *error\_code* &ec = *throws*)

Return priority of the given thread

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn’t throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread whose priority is queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

*std::ptrdiff\_t* **get\_stack\_size**(thread\_id\_type const &id, *error\_code* &ec = *throws*)

Return stack size of the given thread

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn’t throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread whose priority is queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

*threads::thread\_pool\_base* \***get\_pool**(thread\_id\_type const &id, *error\_code* &ec = *throws*)

Returns a pointer to the pool that was used to run the current thread

**Throws** If – &ec != &throws, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside of a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::invalid\_status*.

## hpx/threading\_base/thread\_num\_tss.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

#### `std::size_t get_worker_thread_num()`

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by `get_os_thread_count()`).

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

#### `std::size_t get_worker_thread_num(error_code &ec)`

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by `get_os_thread_count()`). It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

**Parameters** `ec` – [in,out] this represents the error status on exit.

#### `std::size_t get_local_worker_thread_num()`

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

`std::size_t get_local_worker_thread_num(error_code &ec)`

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

**Parameters** `ec` – [in,out] this represents the error status on exit.

`std::size_t get_thread_pool_num()`

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

`std::size_t get_thread_pool_num(error_code &ec)`

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

**Parameters** `ec` – [in,out] this represents the error status on exit.

namespace `threads`

## `hpx/threading_base/thread_pool_base.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **threads**

### Functions

`std::ostream &operator<<(std::ostream &os, thread_pool_base const &thread_pool)`

class **thread\_pool\_base**

`#include <thread_pool_base.hpp>` The base class used to manage a pool of OS threads.

#### Public Functions

virtual void **suspend\_processing\_unit\_direct**(`std::size_t virt_core, error_code &ec = throws`)  
= 0

Suspends the given processing unit. Blocks until the processing unit has been suspended.

**Parameters** **virt\_core** – [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

virtual void **resume\_processing\_unit\_direct**(`std::size_t virt_core, error_code &ec = throws`)  
= 0

Resumes the given processing unit. Blocks until the processing unit has been resumed.

**Parameters** **virt\_core** – [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

virtual void **resume\_direct**(`error_code &ec = throws`) = 0

Resumes the thread pool. Blocks until all OS threads on the thread pool have been resumed.

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

virtual void **suspend\_direct**(`error_code &ec = throws`) = 0

Suspends the thread pool. Blocks until all OS threads on the thread pool have been suspended.

---

**Note:** A thread pool cannot be suspended from an HPX thread running on the pool itself.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Throws** `hpx::exception` – if called from an HPX thread which is running on the pool itself.

struct **thread\_pool\_init\_parameters**

## Public Functions

```
inline thread_pool_init_parameters(std::string const &name, std::size_t index,  
                                policies::scheduler_mode mode, std::size_t num_threads,  
                                std::size_t thread_offset,  
                                hpx::threads::policies::callback_notifier &notifier,

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## **hpx/modules/threadmanager.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **threads**

        class **threadmanager**

```
#include <threadmanager.hpp> The thread-manager class is the central instance of management for  
all (non-depleted) threads
```

### **Public Types**

```
typedef threads::policies::callback_notifier notification_policy_type
```

```
typedef std::unique_ptr<thread_pool_base> pool_type
```

```
typedef threads::policies::scheduler_base scheduler_type
```

```
typedef std::vector<pool_type> pool_vector
```

## Public Functions

```
threadmanager(hpx::util::runtime_configuration &rtcfg_, notification_policy_type &notifier,
              detail::network_background_callback_type network_background_callback =
              detail::network_background_callback_type())

~threadmanager()

void init()

void create_pools()

void print_pools(std::ostream&)

    FIXME move to private and add &#8212;hpx:printpools cmd line option.

thread_pool_base &default_pool() const

scheduler_type &default_scheduler() const

thread_pool_base &get_pool(std::string const &pool_name) const

thread_pool_base &get_pool(pool_id_type const &pool_id) const

thread_pool_base &get_pool(std::size_t thread_index) const

bool pool_exists(std::string const &pool_name) const

bool pool_exists(std::size_t pool_index) const

thread_id_ref_type register_work(thread_init_data &data, error_code &ec = throws)
```

The function `register_work` adds a new work item to the thread manager. It doesn't immediately create a new `thread`, it just adds the task parameters (function, initial state and description) to the internal management data structures. The thread itself will be created when the number of existing threads drops below the number of threads specified by the constructors `max_count` parameter.

### Parameters

- **func** – [in] The function or function object to execute as the thread's function. This must have a signature as defined by `thread_function_type`.
- **description** – [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

```
void register_thread(thread_init_data &data, thread_id_ref_type &id, error_code &ec =
                     throws)
```

The function `register_thread` adds a new work item to the thread manager. It creates a new `thread`, adds it to the internal management data structures, and schedules the new thread, if appropriate.

### Parameters

- **func** – [in] The function or function object to execute as the thread's function. This must have a signature as defined by `thread_function_type`.
- **id** – [out] This parameter will hold the id of the created thread. This id is guaranteed to be validly initialized before the thread function is executed.
- **description** – [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

```
bool run()
```

Run the thread manager's work queue. This function instantiates the specified number of OS threads in each pool. All OS threads are started to execute the function `tfunc`.

---

**Returns** The function returns *true* if the thread manager has been started successfully, otherwise it returns *false*.

void **stop**(bool blocking = true)  
Forcefully stop the thread-manager.  
Parameters **blocking** –

bool **is\_busy**()

bool **is\_idle**()

void **wait**()

void **suspend**()

void **resume**()

inline state **status**() const

Return whether the thread manager is still running This returns the “minimal state”, i.e. the state of the least advanced thread pool.

*std*::int64\_t **get\_thread\_count**(*thread\_schedule\_state* state = *thread\_schedule\_state*::*unknown*,  
*thread\_priority* priority = *thread\_priority*::*default*\_, *std*::size\_t  
num\_thread = *std*::size\_t(-1), bool reset = false)

return the number of HPX-threads with the given state

---

**Note:** This function lock the internal OS lock in the thread manager

---

*std*::int64\_t **get\_idle\_core\_count**()

mask\_type **get\_idle\_core\_mask**()

*std*::int64\_t **get\_background\_thread\_count**()

bool **enumerate\_threads**(*hpx*::function<bool(thread\_id\_type)> const &f, *thread\_schedule\_state*  
state = *thread\_schedule\_state*::*unknown*) const

void **abort\_all\_suspended\_threads**()

bool **cleanup\_terminated**(bool delete\_all)

inline *std*::size\_t **get\_os\_thread\_count**() const

Return the number of OS threads running in this thread-manager.

This function will return correct results only if the thread-manager is running.

inline *std*::thread &**get\_os\_thread\_handle**(*std*::size\_t num\_thread) const

inline void **report\_error**(*std*::size\_t num\_thread, *std*::exception\_ptr const &e)

API functions forwarding to notification policy.

This notifies the thread manager that the passed exception has been raised. The exception will be routed through the notifier and the scheduler (which will result in it being passed to the runtime object, which in turn will report it to the console, etc.).

inline mask\_type **get\_used\_processing\_units**() const

Returns the mask identifying all processing units used by this thread manager.

```
inline hwloc_bitmap_ptr get_pool_numa_bitmap(const std::string &pool_name) const  
inline void set_scheduler_mode(threads::policies::scheduler_mode mode)  
inline void add_scheduler_mode(threads::policies::scheduler_mode mode)  
inline void add_remove_scheduler_mode(threads::policies::scheduler_mode to_add_mode,  
                                    threads::policies::scheduler_mode to_remove_mode)  
inline void remove_scheduler_mode(threads::policies::scheduler_mode mode)  
inline void reset_thread_distribution()  
inline void init_tss(std::size_t global_thread_num)  
inline void deinit_tss()  
std::int64_t get_queue_length(bool reset)  
std::int64_t get_cumulative_duration(bool reset)  
inline std::int64_t get_thread_count_unknown(bool reset)  
inline std::int64_t get_thread_count_active(bool reset)  
inline std::int64_t get_thread_count_pending(bool reset)  
inline std::int64_t get_thread_count_suspended(bool reset)  
inline std::int64_t get_thread_count_terminated(bool reset)  
inline std::int64_t get_thread_count_staged(bool reset)
```

        namespace **execution**

### **hpx/timed\_execution/timed\_execution\_fwd.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

namespace **hpx**

    namespace **parallel**

        namespace **execution**

## **Variables**

*hpx::parallel::execution::post\_at\_t post\_at*

*hpx::parallel::execution::post\_after\_t post\_after*

*hpx::parallel::execution::async\_execute\_at\_t async\_execute\_at*

*hpx::parallel::execution::async\_execute\_after\_t async\_execute\_after*

*hpx::parallel::execution::sync\_execute\_at\_t sync\_execute\_at*

*hpx::parallel::execution::sync\_execute\_after\_t sync\_execute\_after*

```
struct async_execute_after_t : public
    hpx::functional::detail::tag_fallback<async_execute_after_t>
```

*#include <timed\_execution\_fwd.hpp>* Customization point of asynchronous execution agent creation supporting timed execution.

This asynchronously creates a single function invocation f() using the associated executor at the given point in time.

---

**Note:** This calls exec.async\_execute\_after(rel\_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::async\_execute() on the underlying non-time-scheduled execution agent.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.  
**Param rel\_time** [in] The duration of time after which the given function should be scheduled to run.  
**Param f** [in] The function which will be scheduled using the given executor.  
**Param ts...** [in] Additional arguments to use to invoke *f*.  
**Return** *f(ts...)*'s result through a future

### Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(async_execute_after_t, Executor &&exec,
                                               hpx::chrono::steady_duration const
                                               &rel_time, F &&f, Ts&&... ts)
```

```
struct async_execute_at_t : public hpx::functional::detail::tag_fallback<async_execute_at_t>
#include <timed_execution_fwd.hpp> Customization point of asynchronous execution agent creation supporting timed execution.
```

This asynchronously creates a single function invocation *f()* using the associated executor at the given point in time.

---

**Note:** This calls exec.async\_execute\_at(abs\_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::async\_execute() on the underlying non-time-scheduled execution agent.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.  
**Param abs\_time** [in] The point in time the given function should be scheduled at to run.  
**Param f** [in] The function which will be scheduled using the given executor.  
**Param ts...** [in] Additional arguments to use to invoke *f*.  
**Return** *f(ts...)*'s result through a future

### Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(async_execute_at_t, Executor &&exec,
                                               hpx::chrono::steady_time_point const
                                               &abs_time, F &&f, Ts&&... ts)
```

```
struct post_after_t : public hpx::functional::detail::tag_fallback<post_after_t>
#include <timed_execution_fwd.hpp> Customization point of asynchronous fire & forget execution agent creation supporting timed execution.
```

This asynchronously (fire & forget) creates a single function invocation *f()* using the associated executor at the given point in time.

---

**Note:** This calls exec.post\_after(rel\_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::post() on the underlying non-time-scheduled execution agent.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.  
**Param rel\_time** [in] The duration of time after which the given function should be scheduled to run.  
**Param f** [in] The function which will be scheduled using the given executor.  
**Param ts...** [in] Additional arguments to use to invoke *f*.

### Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tagFallbackInvoke(postAfter_t, Executor &&exec,
                                              hpx::chrono::steady_duration const
                                              &rel_time, F &&f, Ts&&... ts)
```

```
struct postAt_t : public hpx::functional::detail::tagFallback<postAt_t>
#include <timed_execution_fwd.hpp> Customization point of asynchronous fire & forget execution agent creation supporting timed execution.
```

This asynchronously (fire & forget) creates a single function invocation *f()* using the associated executor at the given point in time.

---

**Note:** This calls exec.post\_at(abs\_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::post() on the underlying non-time-scheduled execution agent.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.  
**Param abs\_time** [in] The point in time the given function should be scheduled at to run.  
**Param f** [in] The function which will be scheduled using the given executor.  
**Param ts...** [in] Additional arguments to use to invoke *f*.

### Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tagFallbackInvoke(postAt_t, Executor &&exec,
                                              hpx::chrono::steady_time_point const
                                              &abs_time, F &&f, Ts&&... ts)
```

```
struct syncExecuteAfter_t : public
hpx::functional::detail::tagFallback<syncExecuteAfter_t>
#include <timed_execution_fwd.hpp> Customization point of synchronous execution agent creation supporting timed execution.
```

This synchronously creates a single function invocation *f()* using the associated executor at the given point in time.

---

**Note:** This calls `exec.sync_execute_after(rel_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::sync_execute()` on the underlying non-time-scheduled execution agent.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param rel\_time** [in] The duration of time after which the given function should be scheduled to run.

**Param f** [in] The function which will be scheduled using the given executor.

**Param ts...** [in] Additional arguments to use to invoke *f*.

**Return** *f(ts...)*'s result

## Private Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) friend tag_fallback_invoke(sync_execute_after_t, Executor &&exec,
                                                 hpx::chrono::steady_duration const
                                                 &rel_time, F &&f, Ts&&... ts)
```

```
struct sync_execute_at_t : public hpx::functional::detail::tag_fallback<sync_execute_at_t>
#include <timed_execution_fwd.hpp> Customization point of synchronous execution agent creation supporting timed execution.
```

This synchronously creates a single function invocation *f()* using the associated executor at the given point in time.

---

**Note:** This calls `exec.sync_execute_at(abs_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::sync_execute()` on the underlying non-time-scheduled execution agent.

---

**Param exec** [in] The executor object to use for scheduling of the function *f*.

**Param abs\_time** [in] The point in time the given function should be scheduled at to run.

**Param f** [in] The function which will be scheduled using the given executor.

**Param ts...** [in] Additional arguments to use to invoke *f*.

**Return** *f(ts...)*'s result

## Private Functions

## Public Functions

**topology()**

**~topology()**

inline `std::size_t get_socket_number(std::size_t num_thread, error_code& = throws)` const

Return the Socket number of the processing unit the given thread is running on.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

inline `std::size_t get numa_node_number(std::size_t num_thread, error_code& = throws)` const

Return the NUMA node number of the processing unit the given thread is running on.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

mask\_cref\_type **get\_machine\_affinity\_mask(error\_code &ec = throws)** const

Return a bit mask where each set bit corresponds to a processing unit available to the application.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

mask\_type **get\_service\_affinity\_mask(mask\_cref\_type used\_processing\_units, error\_code &ec = throws)** const

Return a bit mask where each set bit corresponds to a processing unit available to the service threads in the application.

**Parameters**

- `used_processing_units` – [in] This is the mask of processing units which are not available for service threads.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

mask\_cref\_type **get\_socket\_affinity\_mask(std::size\_t num\_thread, error\_code &ec = throws)** const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the socket it is running on.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

mask\_cref\_type **get numa\_node\_affinity\_mask(std::size\_t num\_thread, error\_code &ec = throws)** const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the NUMA domain it is running on.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

mask\_type **get numa\_node\_affinity\_mask\_from numa\_node(std::size\_t num\_node)** const

Return a bit mask where each set bit corresponds to a processing unit associated with the given NUMA node.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

mask\_cref\_type **get core affinity mask(std::size\_t num\_thread, error\_code &ec = throws)** const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the core it is running on.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`mask_cref_type get_thread_affinity_mask(std::size_t num_thread, error_code &ec = throws) const`

Return a bit mask where each set bit corresponds to a processing unit available to the given thread.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`void set_thread_affinity_mask(mask_cref_type mask, error_code &ec = throws) const`

Use the given bit mask to set the affinity of the given thread. Each set bit corresponds to a processing unit the thread will be allowed to run on.

---

**Note:** Use this function on systems where the affinity must be set from inside the thread itself.

---

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`mask_type get_thread_affinity_mask_from_lva(void const *lva, error_code &ec = throws) const`

Return a bit mask where each set bit corresponds to a processing unit co-located with the memory the given address is currently allocated on.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`void print_affinity_mask(std::ostream &os, std::size_t num_thread, mask_cref_type m, const std::string &pool_name) const`

Prints the.

**Parameters** `m` – to os in a human readable form

`bool reduce_thread_priority(error_code &ec = throws) const`

Reduce thread priority of the current thread.

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`std::size_t get_number_of_sockets() const`

Return the number of available NUMA domains.

`std::size_t get_number_of numa_nodes() const`

Return the number of available NUMA domains.

`std::size_t get_number_of_cores() const`

Return the number of available cores.

`std::size_t get_number_of_pus() const`

Return the number of available hardware processing units.

`std::size_t get_number_of numa_node_cores(std::size_t numa) const`

Return number of cores in given numa domain.

`std::size_t get_number_of numa_node_pus(std::size_t numa) const`

Return number of processing units in a given numa domain.

`std::size_t get_number_of socket_pus(std::size_t socket) const`

Return number of processing units in a given socket.

```

std::size_t get_number_of_core_pus(std::size_t core) const
    Return number of processing units in given core.

std::size_t get_number_of_socket_cores(std::size_t socket) const
    Return number of cores units in given socket.

inline std::size_t get_core_number(std::size_t num_thread, error_code& = throws) const

std::size_t get_pu_number(std::size_t num_core, std::size_t num_pu, error_code &ec = throws)
    const

mask_type get_cpubind_mask(error_code &ec = throws) const

mask_type get_cpubind_mask(std::thread &handle, error_code &ec = throws) const

hwloc_bitmap_ptr cpuset_to_nodeset(mask_cref_type cpuset) const
    convert a cpu mask into a numa node mask in hwloc bitmap form

void write_to_log() const

void *allocate(std::size_t len) const
    This is equivalent to malloc(), except that it tries to allocate page-aligned memory from the OS.

void *allocate_membind(std::size_t len, hwloc_bitmap_ptr bitmap, hpx_hwloc_membind_policy
    policy, int flags) const
    allocate memory with binding to a numa node set as specified by the policy and flags (see hwloc
    docs)

threads::mask_type get_area_membind_nodeset(const void *addr, std::size_t len) const

bool set_area_membind_nodeset(const void *addr, std::size_t len, void *nodeset) const

int get numa_domain(const void *addr) const

void deallocate(void *addr, std::size_t len) const noexcept
    Free memory that was previously allocated by allocate.

void print_vector(std::ostream &os, std::vector<std::size_t> const &v) const

void print_mask_vector(std::ostream &os, std::vector<mask_type> const &v) const

void print_hwloc(std::ostream&) const

mask_type init_socket_affinity_mask_from_socket(std::size_t num_socket) const

mask_type init numa_node_affinity_mask_from numa_node(std::size_t num numa_node)
    const

mask_type init_core_affinity_mask_from_core(std::size_t num_core, mask_cref_type
    default_mask = empty_mask) const

mask_type init_thread_affinity_mask(std::size_t num_thread) const

mask_type init_thread_affinity_mask(std::size_t num_core, std::size_t num_pu) const

## util

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/util/insert\_checked.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

## Functions

```
template<typename Iterator>
inline bool insert_checked(std::pair<Iterator, bool> const &r)
```

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

**Parameters** **r** – [in] The return value of a std::map insert operation.

**Returns** This function returns **r.second**.

```
template<typename Iterator>
```

inline bool **insert\_checked**(*std::pair<Iterator, bool>* const &r, *Iterator* &it)

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

**Parameters**

- **r** – [in] The return value of a std::map insert operation.
- **r** – [out] A reference to an Iterator, which is set to **r.first**.

**Returns** This function returns **r.second**.

## hpx/util/sed\_transform.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

### Functions

bool **parse\_sed\_expression**(*std::string* const &input, *std::string* &search, *std::string* &replace)

Parse a sed command.

---

**Note:** Currently, only supports search and replace syntax (s/search/replace/)

---

**Parameters**

- **input** – [in] The content to parse.
- **search** – [out] If the parsing is successful, this string is set to the search expression.
- **search** – [out] If the parsing is successful, this string is set to the replace expression.

**Returns** *true* if the parsing was successful, *false* otherwise.

struct **sed\_transform**

#include <sed\_transform.hpp> An unary function object which applies a sed command to its subject and returns the resulting string.

---

**Note:** Currently, only supports search and replace syntax (s/search/replace/)

---

### Public Functions

**sed\_transform**(*std::string* const &search, *std::string* const &replace)

**sed\_transform**(*std::string* const &expression)

*std::string* **operator()** (*std::string* const &input) const

inline explicit **operator bool**() const noexcept

inline bool **operator!()** const

### Defines

#### HPX\_REGISTER\_ACTION\_DECLARATION(...)

Declare the necessary component action boilerplate code.

The macro *HPX\_REGISTER\_ACTION\_DECLARATION* can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
        : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }
    };
}
```

(continues on next page)

(continued from previous page)

```
// Component actions need to be declared, this also defines the
// type 'print_greeting_action' representing the action.
    HPX_DEFINE_COMPONENT_ACTION(server,
        print_greeting, print_greeting_action);
}
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action)
```

**Example:**

---

**Note:** This macro has to be used once for each of the component actions defined using one of the `HPX_DEFINE_COMPONENT_ACTION` macros. It has to be visible in all translation units using the action, thus it is recommended to place it into the header file defining the component.

---

**HPX\_REGISTER\_ACTION\_DECLARATION(...)****HPX\_REGISTER\_ACTION\_DECLARATION\_1(action)****HPX\_REGISTER\_ACTION(...)**

Define the necessary component action boilerplate code.

The macro `HPX_REGISTER_ACTION` can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter `action` is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

---

**Note:** This macro has to be used once for each of the component actions defined using one of the `HPX_DEFINE_COMPONENT_ACTION` or `HPX_DEFINE_PLAIN_ACTION` macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

---

---

**Note:** Only one of the forms of this macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID` should be used for a particular action, never both.

---

**HPX\_REGISTER\_ACTION\_ID(action, actionname, actionid)**

Define the necessary component action boilerplate code and assign a predefined unique id to the action.

The macro `HPX_REGISTER_ACTION` can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter `action` is the type of the action to define the boilerplate for.

The parameter *actionname* specifies an unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

The parameter *actionid* specifies an unique integer value which will be used to represent the action during serialization.

---

**Note:** This macro has to be used once for each of the component actions defined using one of the *HPX\_DEFINE\_COMPONENT\_ACTION* or global actions *HPX\_DEFINE\_PLAIN\_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

---

---

**Note:** Only one of the forms of this macro *HPX\_REGISTER\_ACTION* or *HPX\_REGISTER\_ACTION\_ID* should be used for a particular action, never both.

---

namespace **hpx**

    namespace **actions**

### **hpx/actions\_base/basic\_action\_fwd.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **actions**

```
template<typename Component, typename Signature, typename Derived>
```

```
struct basic_action
```

```
    #include <basic_action_fwd.hpp>
```

**Template Parameters**

- **Component** – component type
- **Signature** – return type and arguments
- **Derived** – derived action class

### **hpx/actions\_base/component\_action.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

## Defines

### `HPX_DEFINE_COMPONENT_ACTION(...)`

Registers a member function of a component as an action type with HPX.

The macro `HPX_DEFINE_COMPONENT_ACTION` can be used to register a member function of a component as an action type named `action_type`.

The parameter `component` is the type of the component exposing the member function `func` which should be associated with the newly defined action type. The parameter `action_type` is the name of the action type to register with HPX.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
        : public hpx::components::component_base<server>
    {
        void print_greeting() const
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting,
            print_greeting_action);
    };
}
```

#### Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending ‘\_action’. The third argument can be omitted only if the second argument with an appended suffix ‘\_action’ resolves to a valid, unqualified C++ type name.

---

**Note:** The macro `HPX_DEFINE_COMPONENT_ACTION` can be used with 2 or 3 arguments. The third argument is optional.

---

namespace `hpx`

namespace `actions`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

#### HPX\_DEFINE\_PLAIN\_ACTION(...)

Defines a plain action type.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // This will define the action type 'app::some_global_action' which
    // represents the function 'app::some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
```

#### Example:

---

**Note:** Usually this macro will not be used in user code unless the intent is to avoid defining the action\_type in global namespace. Normally, the use of the macro `HPX_PLAIN_ACTION` is recommended.

---

**Note:** The macro `HPX_DEFINE_PLAIN_ACTION` can be used with 1 or 2 arguments. The second argument is optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '\_action'. The second argument can be omitted only if the first argument with an appended suffix '\_action' resolves to a valid, unqualified C++ type name.

---

#### HPX\_DECLARE\_PLAIN\_ACTION(...)

Declares a plain action type.

#### HPX\_PLAIN\_ACTION(...)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro `HPX_PLAIN_ACTION` can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *name* representing the given function. This macro additionally registers the newly define action type with HPX.

The parameter *func* is a global or free (non-member) function which should be encapsulated into a plain action. The parameter *name* is the name of the action type defined by this macro.

```

namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // This will define the action type 'some_global_action' which represents
    // the function 'app::some_global_function'.
    HPX_PLAIN_ACTION(app::some_global_function, some_global_action)
}

```

**Example:**

---

**Note:** The macro *HPX\_PLAIN\_ACTION* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

---

**Note:** The macro *HPX\_PLAIN\_ACTION\_ID* can be used with 1, 2, or 3 arguments. The second and third arguments are optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending ‘\_action’. The second argument can be omitted only if the first argument with an appended suffix ‘\_action’ resolves to a valid, unqualified C++ type name. The default value for the third argument is *hpx::components::factory\_check*.

---

**Note:** Only one of the forms of this macro *HPX\_PLAIN\_ACTION* or *HPX\_PLAIN\_ACTION\_ID* should be used for a particular action, never both.

---

**HPX\_PLAIN\_ACTION\_ID(func, name, id)**

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX\_PLAIN\_ACTION\_ID* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *actionname* representing the given function. The parameter *actionid*

The parameter *actionid* specifies an unique integer value which will be used to represent the action during serialization.

The parameter *func* is a global or free (non-member) function which should be encapsulated into a plain action. The parameter *name* is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

```

namespace app
{
    void some_global_function(double d)
    {
        cout << d;
}

```

(continues on next page)

(continued from previous page)

```
    }  
  
    // This will define the action type 'some_global_action' which represents  
    // the function 'app::some_global_function'.  
    HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,  
    some_unique_id);
```

---

**Example:**

---

**Note:** The macro *HPX\_PLAIN\_ACTION\_ID* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

---

---

**Note:** Only one of the forms of this macro *HPX\_PLAIN\_ACTION* or *HPX\_PLAIN\_ACTION\_ID* should be used for a particular action, never both.

std::uint64_t get_cache_erase_entry_time(bool reset)

bool register_locality(parcelset::endpoints_type const &endpoints, naming::gid_type &prefix,
                      std::uint32_t num_threads, error_code &ec = throws)
```

Add a locality to the runtime.

```
parcelset::endpoints_type const &resolve_locality(naming::gid_type const &gid, error_code
&ec = throws)
```

Resolve a locality to its prefix.

**Returns** Returns an empty vector if the locality is not registered.

```
bool has_resolved_locality(naming::gid_type const &gid)
```

```
bool unregister_locality(naming::gid_type const &gid, error_code &ec = throws)
```

Remove a locality from the runtime.

```
void remove_resolved_locality(naming::gid_type const &gid)
```

remove given locality from locality cache

```
bool get_console_locality(naming::gid_type &locality, error_code &ec = throws)
```

Get locality locality\_id of the console locality.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **locality\_id** – [out] The locality\_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
- **try\_cache** – [in] If this is set to true the console is first tried to be found in the local cache. Otherwise this function will always query AGAS, even if the console locality\_id is already known locally.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true* if a console locality\_id exists and returns *false* otherwise.

```
bool get_localities(std::vector<naming::gid_type> &locality_ids,  
                     components::component_type type, error_code &ec = throws)
```

Query for the locality\_ids of all known localities.

This function returns the locality\_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **locality\_ids** – [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime\_support components of these localities.
- **type** – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component\_invalid*, which will return prefixes of all localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
inline bool get_localities(std::vector<naming::gid_type> &locality_ids, error_code &ec =  
                           throws)
```

```
hpx::future<std::uint32_t> get_num_localities_async(components::component_type type =  
                                                 components::component_invalid) const
```

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **type** – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component\_invalid*, which will return prefixes of all localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
std::uint32_t get_num_localities(components::component_type type, error_code &ec = throws)  
const
```

```
inline std::uint32_t get_num_localities(error_code &ec = throws) const
```

```
hpx::future<std::uint32_t> get_num_overall_threads_async() const
```

```
std::uint32_t get_num_overall_threads(error_code &ec = throws) const
```

```
hpx::future<std::vector<std::uint32_t>> get_num_threads_async() const
```

```
std::vector<std::uint32_t> get_num_threads(error_code &ec = throws) const
```

---

```
components::component_type get_component_id(std::string const &name, error_code &ec =
    throws)
```

Return a unique id usable as a component type.

This function returns the component type id associated with the given component name. If this is the first request for this component name a new unique id will be created.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

#### Parameters

- **name** – [in] The component name (string) to get the component type for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** The function returns the currently associated component type. Any error results in an exception thrown from this function.

```
void iterate_types(iterate_types_function_type const &f, error_code &ec = throws)

std::string get_component_type_name(components::component_type id, error_code &ec =
    throws)
```

```
inline components::component_type register_factory(naming::gid_type const &locality_id,
    std::string const &name, error_code &ec =
    throws)
```

Register a factory for a specific component type.

This function allows to register a component factory for a given locality and component type.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

#### Parameters

- **locality\_id** – [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- **name** – [in] The component name (string) to register a factory for the given component type for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function *get\_component\_id* was called using the same component name.

```
components::component_type register_factory(uint32_t locality_id, std::string const
    &name, error_code &ec = throws)
```

```
bool get_id_range(uint64_t count, naming::gid_type &lower_bound, naming::gid_type
    &upper_bound, error_code &ec = throws)
```

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

---

**Note:** This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling *bind* or *bind\_range*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **l** – [in] The locality the locality id needs to be generated for. Repeating calls using the same locality results in identical locality\_id values.
- **count** – [in] The number of global ids to be generated.
- **lower\_bound** – [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
- **upper\_bound** – [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

```
inline bool bind_local(naming::gid_type const &id, naming::address const &addr, error_code&ec = throws)
```

Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** Binding a gid to a local address sets its global reference count to one.

---

#### Parameters

- **id** – [in] The global address which has to be bound to the local address.
- **addr** – [in] The local address to be bound to the global address.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true*, if this global id got associated with an local address. It returns *false* otherwise.

```
inline hpx::future<bool> bind_async(naming::gid_type const &id, naming::address const &addr, std::uint32_t locality_id)
```

```
inline hpx::future<bool> bind_async(naming::gid_type const &id, naming::address const &addr, naming::gid_type const &locality)
```

---

```
bool bind_range_local(naming::gid_type const &lower_id, std::uint64_t count, naming::address
const &baseaddr, std::uint64_t offset, error_code &ec = throws)
```

Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given *offset*).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Note:** Binding a gid to a local address sets its global reference count to one.

---

#### Parameters

- **lower\_id** – [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
- **count** – [in] The number of consecutive global ids to bind starting at *lower\_id*.
- **baseaddr** – [in] The local address to bind to the global id given by *lower\_id*. This is the base address for all additional local addresses to bind to the remaining global ids.
- **offset** – [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true*, if the given range was successfully bound. It returns *false* otherwise.

```
hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t count,
naming::address const &baseaddr, std::uint64_t offset,
naming::gid_type const &locality)
```

```
inline hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t
count, naming::address const &baseaddr,
std::uint64_t offset, std::uint32_t locality_id)
```

```
inline bool unbind_local(naming::gid_type const &id, error_code &ec = throws)
```

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

---

**Note:** You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind\_range*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

TODO: confirm that this happens.

---

**Parameters**

- **id** – [in] The global address (id) for which the association has to be removed.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The function returns `true` if the association has been removed, and it returns `false` if no association existed. Any error results in an exception thrown from this function.

```
inline bool unbind_local(naming::gid_type const &id, naming::address &addr, error_code &ec = throws)
```

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

---

**Note:** You can unbind only global ids bound using the function `bind`. Do not use this function to unbind any of the global ids bound using `bind_range`.

---

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!  
TODO: confirm that this happens.

---

**Parameters**

- **id** – [in] The global address (id) for which the association has to be removed.
- **addr** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The function returns `true` if the association has been removed, and it returns `false` if no association existed. Any error results in an exception thrown from this function.

```
inline bool unbind_range_local(naming::gid_type const &lower_id, std::uint64_t count, error_code &ec = throws)
```

Unbind the given range of global ids.

---

**Note:** You can unbind only global ids bound using the function `bind_range`. Do not use this function to unbind any of the global ids bound using `bind`.

---

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

TODO: confirm that this happens.

---

#### Parameters

- **lower\_id** – [in] The lower bound of the assigned id range. The value must be the first id of the range as specified to the corresponding call to *bind\_range*.
- **count** – [in] The number of consecutive global ids to unbind starting at *lower\_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind\_range*
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

```
bool unbind_range_local(naming::gid_type const &lower_id, std::uint64_t count,  
                      naming::address &addr, error_code &ec = throws)
```

Unbind the given range of global ids.

---

**Note:** You can unbind only global ids bound using the function *bind\_range*. Do not use this function to unbind any of the global ids bound using *bind*.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

#### Parameters

- **lower\_id** – [in] The lower bound of the assigned id range. The value must be the first id of the range as specified to the corresponding call to *bind\_range*.
- **count** – [in] The number of consecutive global ids to unbind starting at *lower\_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind\_range*
- **addr** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call.

```
hpx::future<naming::address> unbind_range_async(naming::gid_type const &lower_id,  
                                         std::uint64_t count = 1)
```

inline bool **is\_local\_address\_cached**(*naming*::gid\_type const &id, *error\_code* &ec = *throws*)

Test whether the given address refers to a local object.

This function will test whether the given address refers to an object living on the locality of the caller.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns

the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

---

#### Parameters

- **addr** – [in] The address to test.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true* if the passed address refers to an object which lives on the locality of the caller.

```
bool is_local_address_cached(naming::gid_type const &id, naming::address &addr,  
                           error_code &ec = throws)  
  
bool is_local_lva_encoded_address(std::uint64_t msb)  
  
inline bool resolve_local(naming::gid_type const &id, naming::address &addr, error_code &ec  
                         = throws)
```

Resolve a given global address (*id*) to its associated local address.

This function returns the local address which is currently associated with the given global address (*id*).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

---

#### Parameters

- **id** – [in] The global address (*id*) for which the associated local address should be returned.
- **addr** – [out] The local address which currently is associated with the given global address (*id*), this is valid only if the return value of this function is *true*.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns *true* if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The function returns *false* if no association exists for the given global address. Any error results in an exception thrown from this function.

```
inline bool resolve_local(hpx::id_type const &id, naming::address &addr, error_code &ec =  
                         throws)  
  
inline naming::address resolve_local(naming::gid_type const &id, error_code &ec = throws)  
  
inline naming::address resolve_local(hpx::id_type const &id, error_code &ec = throws)  
  
hpx::future<naming::address> resolve_async(naming::gid_type const &id)  
  
inline hpx::future<naming::address> resolve_async(hpx::id_type const &id)  
  
hpx::future<hpx::id_type> get_colocation_id_async(hpx::id_type const &id)  
  
bool resolve_full_local(naming::gid_type const &id, naming::address &addr, error_code &ec  
                         = throws)  
  
inline bool resolve_full_local(hpx::id_type const &id, naming::address &addr, error_code &ec  
                           = throws)
```

---

```

inline naming::address resolve_full_local(naming::gid_type const &id, error_code &ec =
throws)

inline naming::address resolve_full_local(hpx::id_type const &id, error_code &ec = throws)

hpx::future<naming::address> resolve_full_async(naming::gid_type const &id)

inline hpx::future<naming::address> resolve_full_async(hpx::id_type const &id)

bool resolve_cached(naming::gid_type const &id, naming::address &addr, error_code &ec =
throws)

inline bool resolve_cached(hpx::id_type const &id, naming::address &addr, error_code &ec =
throws)

inline bool resolve_local(naming::gid_type const *gids, naming::address *addrs, std::size_t size,
hpx::detail::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_full_local(naming::gid_type const *gids, naming::address *addrs, std::size_t size,
hpx::detail::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_cached(naming::gid_type const *gids, naming::address *addrs, std::size_t size,
hpx::detail::dynamic_bitset<> &locals, error_code &ec = throws)

hpx::future<std::int64_t> inref_async(naming::gid_type const &gid, std::int64_t credits = 1,
hpx::id_type const &keep_alive = hpx::invalid_id)

```

Increment the global reference count for the given id.

---

**Note:** As long as *ec* is not pre-initialized to *hpx*::*throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx*::exception.

#### Parameters

- **id** – [in] The global address (id) for which the global reference count has to be incremented.
- **credits** – [in] The number of reference counts to add for the given id.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx*::*throws* the function will throw on error instead.

**Returns** Whether the operation was successful.

```
inline std::int64_t inref(naming::gid_type const &gid, std::int64_t credits = 1, error_code &ec =
throws)
```

```
void decref(naming::gid_type const &id, std::int64_t credits = 1, error_code &ec = throws)
```

Decrement the global reference count for the given id.

---

**Note:** As long as *ec* is not pre-initialized to *hpx*::*throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx*::exception.

#### Parameters

- **id** – [in] The global address (id) for which the global reference count has to be decremented.
- **t** – [out] If this was the last outstanding global reference for the given gid (the return value of this function is zero), t will be set to the component type of the corresponding element. Otherwise t will not be modified.

- **credits** – [in] The number of reference counts to add for the given id.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The global reference count after the decrement.

`hpx::future<iterate_names_return_type> iterate_ids(std::string const &pattern)`

Invoke the supplied `hpx::function` for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

**Parameters** **pattern** – [in] pattern (possibly using wildcards) to match all existing entries against

`bool register_name(std::string const &name, naming::gid_type const &id, error_code &ec = throws)`

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

#### Parameters

- **name** – [in] The global name (string) to be associated with the global address.
- **id** – [in] The global address (id) to be associated with the global address.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The function returns `true` if the global name was registered. It returns false if the global name is not registered.

`hpx::future<bool> register_name_async(std::string const &name, hpx::id_type const &id)`

`bool register_name(std::string const &name, hpx::id_type const &id, error_code &ec = throws)`

`hpx::future<hpx::id_type> unregister_name_async(std::string const &name)`

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

#### Parameters

- **name** – [in] The global name (string) for which any association with a global address (id) has to be released.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The function returns `true` if an association of this global name has been released, and it returns `false`, if no association existed. Any error results in an exception thrown from this function.

`hpx::id_type unregister_name(std::string const &name, error_code &ec = throws)`

---

`hpx::future<hpx::id_type> resolve_name_async(std::string const &name)`

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

This function returns true if it returned global address (id), which is currently associated with the given global name, and it returns false, if currently there is no association for this global name. Any error results in an exception thrown from this function.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

#### Parameters

- `name` – [in] The global name (string) for which the currently associated global address has to be retrieved.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** [out] The id currently associated with the given global name (valid only if the return value is true).

`hpx::id_type resolve_name(std::string const &name, error_code &ec = throws)`

`future<hpx::id_type> on_symbol_namespace_event(std::string const &name, bool call_for_past_events = false)`

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.

---

**Note:** The only event type which is currently supported is `symbol_ns_bind`, i.e. the listener is triggered whenever a global id is registered with the given name.

#### Parameters

- `name` – [in] The global name (string) for which the given event should be triggered.
- `evt` – [in] The event for which a listener should be installed.
- `call_for_past_events` – [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is `false`.

**Returns** A future instance encapsulating the global id which is causing the registered listener to be triggered.

`void update_cache_entry(naming::gid_type const &gid, gva const &gva, error_code &ec = throws)`

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

inline void `update_cache_entry(naming::gid_type const &gid, naming::address const &addr, std::uint64_t count = 0, std::uint64_t offset = 0, error_code &ec = throws)`

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
bool get_cache_entry(naming::gid_type const &gid, gva &gva, naming::gid_type &idbase,  
error_code &ec = throws)
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
void remove_cache_entry(naming::gid_type const &id, error_code &ec = throws)
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
void clear_cache(error_code &ec = throws)
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
void start_shutdown(error_code &ec = throws)
```

*hpx*::*future*<*std*::pair<*hpx*::id\_type, *naming*::address>> **begin\_migration**(*hpx*::id\_type const &id)  
start/stop migration of an object

**Returns** Current locality and address of the object to migrate

```
bool end_migration(hpx::id_type const &id)
```

*std*::pair<bool, *components*::pinned\_ptr> **was\_object\_migrated**(*naming*::gid\_type const &gid,  
*hpx*::move\_only\_function<*components*::pinned\_ptr  
&&f>)

Maintain list of migrated objects.

*hpx*::*future*<void> **mark\_as\_migrated**(*naming*::gid\_type const &gid,  
*hpx*::move\_only\_function<*std*::pair<bool,  
*hpx*::*future*<void>>() &&f, bool  
expect\_to\_be\_marked\_as\_migrating)

Mark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

```
void unmark_as_migrated(naming::gid_type const &gid)
```

Remove the given object from the table of migrated objects.

```
void pre_cache_endpoints(std::vector<parcels::endpoints_type> const&)
```

### Functions

*naming*::gid\_type **bootstrap\_primary\_namespace\_gid()**

*hpx*::id\_type **bootstrap\_primary\_namespace\_id()**

namespace **server**

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

	-----MSB-----   -----LSB-----
	BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
	prefix  RC  ---identifier---
MSB	- Most significant bits (bit 64 to bit 127)
LSB	- Least significant bits (bit 0 to bit 63)
prefix	- Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.
RC	- Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID. Bit 93 is used by the locking scheme for gid_types. Bit 94 is a flag which is set if the credit value is valid. Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality). - Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).
identifier	- Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For

(continues on next page)

(continued from previous page)

```
\a hpx#components#component_runtime_support the high 24
bits are zeroed and the low 64 bits hold the LVA of the
component.
```

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

<code>00000000xxxxxxxxxxxxxxxxxxxxxx</code>	Historically unused address space reserved <b>for</b> future use.
<code>xxxxxxxxxx0000xxxxxxxxxxxxxx</code>	Address space <b>for</b> LVA-encoded GIDs.
<code>00000001xxxxxxxxxxxxxxxxxxxxxx</code>	Prefix of the bootstrap AGAS locality.
<code>00000001000000010000000000000001</code>	Address of the primary_namespace component on the bootstrap AGAS locality.
<code>00000001000000010000000000000002</code>	Address of the component_namespace component on the bootstrap AGAS locality.
<code>00000001000000010000000000000003</code>	Address of the symbol_namespace component on the bootstrap AGAS locality.
<code>00000001000000010000000000000004</code>	Address of the locality_namespace component on the bootstrap AGAS locality.

---

**Note:** The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

---

### async\_colocated

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/async\_colocated/get\_colocation\_id.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

*hpx::id\_type* **get\_colocation\_id**(*launch::sync\_policy*, *hpx::id\_type const &id*, *error\_code &ec* = *throws*)

Return the id of the locality where the object referenced by the given id is currently located on.

The function *hpx::get\_colocation\_id()* returns the id of the locality where the given object is currently located.

### See also:

[hpx::get\\_colocation\\_id\(\)](#)

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

## Parameters

- **id** – [in] The id of the object to locate.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

*hpx::future<hpx::id\_type>* **get\_colocation\_id**(*hpx::id\_type const &id*)

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

### See also:

[hpx::get\\_colocation\\_id\(\*launch::sync\\_policy\*\)](#)

**Parameters** **id** – [in] The id of the object to locate.

### async\_distributed

See *Public API* for a list of names and headers that are part of the public HPX API.

## hpx/async\_distributed/base\_lco.hpp

```
class base_lco
```

```
#include <base_lco.hpp> The base_lco class is the common base class for all LCO's implementing a simple set_event action
```

```
Subclassed by hpx::lcos::base_lco_with_value< Result, RemoteResult, ComponentTag >, hpx::lcos::base_lco_with_value< void, void, ComponentTag >
```

## Public Types

`typedef components::managed_component<base_lco> wrapping_type`

`typedef base_lco base_type_holder`

## Public Functions

`virtual void set_event() = 0`

`virtual void set_exception(std::exception_ptr const &e)`

`virtual void connect(hpx::id_type const&)`

`virtual void disconnect(hpx::id_type const&)`

`virtual ~base_lco()`

Destructor, needs to be virtual to allow for clean destruction of derived objects

`virtual void finalize()`

`finalize()` will be called just before the instance gets destructed

`void set_event_nonvirt()`

The *function* `set_event_nonvirt` is called whenever a `set_event_action` is applied on a instance of a LCO. This function just forwards to the virtual function `set_event`, which is overloaded by the derived concrete LCO.

`void set_exception_nonvirt(std::exception_ptr const &e)`

The *function* `set_exception` is called whenever a `set_exception_action` is applied on a instance of a LCO. This function just forwards to the virtual function `set_exception`, which is overloaded by the derived concrete LCO.

**Parameters** `e` – [in] The exception encapsulating the error to report to this LCO instance.

`void connect_nonvirt(hpx::id_type const &id)`

The *function* `connect_nonvirt` is called whenever a `connect_action` is applied on a instance of a LCO. This function just forwards to the virtual function `connect`, which is overloaded by the derived concrete LCO.

**Parameters** `id` – [in] target id

`void disconnect_nonvirt(hpx::id_type const &id)`

The *function* `disconnect_nonvirt` is called whenever a `disconnect_action` is applied on a instance of a LCO. This function just forwards to the virtual function `disconnect`, which is overloaded by the derived concrete LCO.

**Parameters** `id` – [in] target id

`HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco, set_event_nonvirt,  
set_event_action) HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco`

Each of the exposed functions needs to be encapsulated into an action type, allowing to generate all required boilerplate code for threads, serialization, etc.

The `set_event_action` may be used to unconditionally trigger any LCO instances, it carries no additional parameters. The `set_exception_action` may be used to transfer arbitrary error information from the remote site to the LCO instance specified as a continuation. This action carries 2 parameters:

**Parameters** `std::exception_ptr` – [in] The exception encapsulating the error to report to this LCO instance.

`set_exception_action HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco,  
connect_nonvirt, connect_action) HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco`

The `connect_action` may be used to.

The `set_exception_action` may be used to

namespace **hpx**

namespace **components**

namespace **lcos**

```
template<typename Result, typename RemoteResult, typename ComponentTagbase_lco_with_value : public hpx::lcos::base_lco, public ComponentTag
#include <base_lco_with_value.hpp> The base_lco_with_value class is the common base class for all LCO's synchronizing on a value. The RemoteResult template argument should be set to the type of the argument expected for the set_value action.
```

#### Template Parameters

- **RemoteResult** – The type of the result value to be carried back to the LCO instance.
- **ComponentTag** – The tag type representing the type of the component (either **component\_tag** or **managed\_component\_tag**).

## Public Types

```
using wrapping_type = typename detail::base_lco_wrapping_type<ComponentTag,  
base_lco_with_value>::type
```

```
using base_type_holder = base_lco_with_value
```

## Public Functions

```
inline void set_value_nonvirt(RemoteResult &&result)
```

The *function* **set\_value\_nonvirt** is called whenever a *set\_value\_action* is applied on this LCO instance. This function just forwards to the virtual function **set\_value**, which is overloaded by the derived concrete LCO.

**Parameters** **result** – [in] The result value to be transferred from the remote operation back to this LCO instance.

```
inline Result get_value_nonvirt()
```

The *function* **get\_result\_nonvirt** is called whenever a *get\_result\_action* is applied on this LCO instance. This function just forwards to the virtual function **get\_result**, which is overloaded by the derived concrete LCO.

```
HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco_with_value, set_value_nonvirt,
set_value_action) HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco_with_value
```

The *set\_value\_action* may be used to trigger any LCO instances while carrying an additional parameter of any type.

RemoteResult is taken by rvalue ref. This allows for perfect forwarding. When the action thread function is created, the values are moved into the called function. If we took it by const lvalue reference, we would disable the possibility to further move the result to the designated destination.

**Parameters** **RemoteResult** – [in] The type of the result to be transferred back to this LCO instance. The *get\_value\_action* may be used to query the value this LCO instance exposes as its ‘result’ value.

## hpx/async\_distributed/lcos\_fwd.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
namespace distributed
```

```
template<typename Result, typename RemoteResult>
```

```
class promise
```

*#include <promise.hpp>* A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO's set\_event action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)  
hpx::distributed::promise<hpx::id_type> p;  
  
// Get the associated future  
future<hpx::id_type> f = p.get_future();  
  
// initiate the action supplying the promise as a
```

(continues on next page)

(continued from previous page)

```
// continuation
apply<some_action>(new continuation(p.get_id()), ...);

// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

---

**Note:** The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

---

#### Template Parameters

- **Result** – The template parameter *Result* defines the type this promise is expected to return from *promise::get*.
- **RemoteResult** – The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

namespace **lcos**

#### TypeDefs

```
using instead = hpx::distributed::promise<Result, RemoteResult>

template<typename Result, typename RemoteResult, typename ComponentTag>
class base_lco_with_value : public hpx::lcos::base_lco, public ComponentTag
    #include <base_lco_with_value.hpp>
template<typename ValueType>
struct object_semaphore

template<typename Action, typename Result = typename traits::promise_local_result<typename Action::remote_result_type>::type, bool DirectExecute = Action::direct_execution::value>
class packaged_action
    #include <packaged_action.hpp> A packaged_action can be used by a single thread to invoke a (remote) action and wait for the result. The result is expected to be sent back to the packaged_action using the LCO's set_event action
```

A *packaged\_action* is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*.

---

**Note:** The action executed using the *packaged\_action* as a continuation must return a value of a type convertible to the type as specified by the template parameter *Result*.

---

#### Template Parameters

- **Action** – The template parameter *Action* defines the action to be executed by this *packaged\_action* instance. The arguments *arg0, ..., argN* are used as parameters for this action.

- **Result** – The template parameter *Result* defines the type this *packaged\_action* is expected to return from its associated future *packaged\_action::get\_future*.
- **DirectExecute** – The template parameter *DirectExecute* is an optimization aid allowing to execute the action directly if the target is local (without spawning a new thread for this). This template does not have to be supplied explicitly as it is derived from the template parameter *Action*.

```
namespace server

template<typename ValueType>
struct object_semaphore

## Private Types

using **action\_type** = typename *packaged\_action*<*Action*, *Result*, false>::action\_type

## `hpx/async_distributed/promise.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

template<>

```
class hpx::distributed::promise<void, hpx::util::unused_type> : public lcos::detail::promise_base<void, hpx::util::unused_type, lcos::detail::promise_data<void>>
```

## Public Functions

**promise()** = default

constructs a promise object and a shared state.

template<typename **Allocator**>

inline **promise**(*std*::allocator\_arg\_t, *Allocator* const &a)

constructs a promise object and a shared state. The constructor uses the allocator a to allocate the memory for the shared state.

```
promise(promise &&other) noexcept = default
    constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly-constructed object.

Post other has no shared state.

~promise() = default
    Abandons any shared state.

promise &operator=(promise &&other) noexcept = default
    Abandons any shared state (30.6.4) and then as if promise(HPX_MOVE(other)).swap(*this).

Returns *this.

inline void swap(promise &other) noexcept
    Exchanges the shared state of *this and other.

Post *this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

inline void set_value()
    atomically stores the value r in the shared state and makes that state ready (30.6.4).

Throws future_error – if its shared state already has a stored value. if shared state has no stored value exception is raised. promise_already_satisfied if its shared state already has a stored value or exception. no_state if *this has no shared state.
```

## Private Types

```
using base_type = lcos::detail::promise_base<void, hpx::util::unused_type,
lcos::detail::promise_data<void>>

template<typename R, typename Allocator>
struct uses_allocator<hpx::distributed::promise<R>, Allocator> : public true_type
    #include <promise.hpp> Requires: Allocator shall be an allocator (17.6.3.5)

namespace hpx

namespace distributed
```

## Functions

```
template<typename Result, typename RemoteResult>
void swap(promise<Result, RemoteResult> &x, promise<Result, RemoteResult> &y) noexcept

template<typename Result, typename RemoteResult>
class promise
    #include <promise.hpp>

    template<> unused_type > : public lcos::detail::promise_base< void,
hpx::util::unused_type, lcos::detail::promise_data< void > >
```

## Public Functions

**promise()** = default

constructs a promise object and a shared state.

template<typename **Allocator**>

inline **promise**(*std*::allocator\_arg\_t, *Allocator* const &a)

constructs a promise object and a shared state. The constructor uses the allocator a to allocate the memory for the shared state.

**promise**(*promise* &&*other*) noexcept = default

constructs a new promise object and transfers ownership of the shared state of *other* (if any) to the newly-constructed object.

**Post** *other* has no shared state.

**~promise()** = default

Abandons any shared state.

*promise* &**operator=**(*promise* &&*other*) noexcept = default

Abandons any shared state (30.6.4) and then as if *promise*(HPX\_MOVE(*other*)).*swap*(\*this).

**Returns** \*this.

inline void **swap**(*promise* &*other*) noexcept

Exchanges the shared state of \*this and *other*.

**Post** \*this has the shared state (if any) that *other* had prior to the call to *swap*. *other* has the shared state (if any) that \*this had prior to the call to *swap*.

inline void **set\_value()**

atomically stores the value r in the shared state and makes that state ready (30.6.4).

**Throws** *future\_error* – if its shared state already has a stored value. if shared state has no stored value exception is raised. *promise\_already\_satisfied* if its shared state already has a stored value or exception. *no\_state* if \*this has no shared state.

## Private Types

### Functions

void **trigger\_lco\_event**(*hpx::id\_type const &id, naming::address &&addr, bool move\_credits = true*)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **trigger\_lco\_event**(*hpx::id\_type const &id, bool move\_credits = true*)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **trigger\_lco\_event**(*hpx::id\_type const &id, naming::address &&addr, hpx::id\_type const &cont, bool move\_credits = true*)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
inline void trigger_lco_event(hpx::id_type const &id, hpx::id_type const &cont, bool move_credits = true)
```

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>
void set_lco_value(hpx::id_type const &id, naming::address &&addr, Result &&t, bool move_credits = true)
```

Set the result value for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type set_lco_value(hpx::id_type const &id, Result &&t, bool move_credits = true)
```

Set the result value for the (managed) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type set_lco_value_unmanaged
```

Set the result value for the (unmanaged) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>
void set_lco_value(hpx::id_type const &id, naming::address &&addr, Result &&t, hpx::id_type const
&cont, bool move_credits = true)
```

Set the result value for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type set_lco_value(hpx::id_type
const
&id,
Re-
sult
&&t,
hpx::id_type
const
&cont,
bool
move_credits
=
true)
```

Set the result value for the (managed) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>
```

---

```
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>>::value>::type set_lco_value_unmanaged
```

Set the result value for the (unmanaged) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
void set_lco_error(hpx::id_type const &id, naming::address &&addr, std::exception_ptr const &e, bool move_credits = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
void set_lco_error(hpx::id_type const &id, naming::address &&addr, std::exception_ptr &&e, bool move_credits = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
inline void set_lco_error(hpx::id_type const &id, std::exception_ptr const &e, bool move_credits = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.

- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set\_lco\_error**(*hpx*::id\_type const &*id*, *std*::exception\_ptr &&*e*, bool *move\_credits* = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set\_lco\_error**(*hpx*::id\_type const &*id*, *naming*::address &&*addr*, *std*::exception\_ptr const &*e*,  
*hpx*::id\_type const &*cont*, bool *move\_credits* = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set\_lco\_error**(*hpx*::id\_type const &*id*, *naming*::address &&*addr*, *std*::exception\_ptr &&*e*,  
*hpx*::id\_type const &*cont*, bool *move\_credits* = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set\_lco\_error**(*hpx*::id\_type const &*id*, *std*::exception\_ptr const &*e*, *hpx*::id\_type const &*cont*,  
bool *move\_credits* = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

---

```
inline void set_lco_error(hpx::id_type const &id, std::exception_ptr &&e, hpx::id_type const &cont, bool move_credits = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

## checkpoint

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### **hpx/checkpoint/checkpoint.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

This header defines the save\_checkpoint and restore\_checkpoint functions. These functions are designed to help HPX application developer's checkpoint their applications. Save\_checkpoint serializes one or more objects and saves them as a byte stream. Restore\_checkpoint converts the byte stream back into instances of the objects.

namespace **hpx**

namespace **util**

#### Functions

```
inline std::ostream &operator<<(std::ostream &ost, checkpoint const &ckp)
      Operator<< Overload
```

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

#### Parameters

- **ost** – Output stream to write to.
- **ckp** – Checkpoint to copy from.

**Returns** Operator<< returns the ostream object.

```
inline std::istream &operator>>(std::istream &ist, checkpoint &ckp)
      Operator>> Overload
```

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be

mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

**Parameters**

- **ist** – Input stream to write from.
- **ckp** – Checkpoint to write to.

**Returns** Operator`>>` returns the ostream object.

```
template<typename T, typename ...Ts, typename U = typename
std::enable_if<!hpx::traits::is_launch_policy<T>::value && !std::is_same<typename
std::decay<T>::type, checkpoint>::value>::type>
hpx::future<checkpoint> save_checkpoint(T &&t, Ts&&... ts)
```

Save\_checkpoint

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

**Parameters**

- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Save\_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save\_checkpoint will simply return a checkpoint.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint(checkpoint &&c, T &&t, Ts&&... ts)
```

Save\_checkpoint - Take a pre-initialized checkpoint

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

**Parameters**

- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Save\_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save\_checkpoint will simply return a checkpoint.

```
template<typename T, typename ...Ts, typename U = typename std::enable_if<!std::is_same<typename std::decay<T>::type, checkpoint>::value>::type>
hpx::future<checkpoint> save_checkpoint(hpx::launch p, T &&t, Ts&&... ts)
```

Save\_checkpoint - Policy overload

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

#### Template Parameters

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

#### Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Save\_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save\_checkpoint will simply return a checkpoint.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint(hpx::launch p, checkpoint &&c, T &&t, Ts&&... ts)
```

Save\_checkpoint - Policy overload & pre-initialized checkpoint

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

#### Template Parameters

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

#### Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Save\_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save\_checkpoint will simply return a

checkpoint.

```
template<typename T, typename ...Ts, typename U = typename std::enable_if<!std::is_same<typename std::decay<T>::type, checkpoint>::value>::type>
checkpoint save_checkpoint(hpx::launch::sync_policy sync_p, T &&t, Ts&&... ts)
Save_checkpoint - Sync_policy overload
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

#### Template Parameters

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

#### Parameters

- **sync\_p** – hpx::launch::sync\_policy
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Save\_checkpoint which is passed hpx::launch::sync\_policy will return a checkpoint which contains the serialized values checkpoint.

```
template<typename T, typename ...Ts>
checkpoint save_checkpoint(hpx::launch::sync_policy sync_p, checkpoint &&c, T &&t, Ts&&... ts)
Save_checkpoint - Sync_policy overload & pre-init. checkpoint
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

#### Template Parameters

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

#### Parameters

- **sync\_p** – hpx::launch::sync\_policy
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Save\_checkpoint which is passed hpx::launch::sync\_policy will return a checkpoint which contains the serialized values checkpoint.

```
template<typename T, typename ...Ts, typename U = typename std::enable_if<!hpx::traits::is_launch_policy<T>::value && !std::is_same<typename std::decay<T>::type, checkpoint>::value>::type>
```

---

`hpx::future<checkpoint> prepare_checkpoint(T const &t, Ts const&... ts)`  
 prepare\_checkpoint

prepare\_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore\_checkpoint invocation. prepare\_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

#### Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

#### Parameters

- **t** – A container to restore.
- **ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Returns** prepare\_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore\_checkpoint operation.

`template<typename T, typename ...Ts>`  
`hpx::future<checkpoint> prepare_checkpoint(checkpoint &&c, T const &t, Ts const&... ts)`  
 prepare\_checkpoint

prepare\_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore\_checkpoint invocation. prepare\_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

#### Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

#### Parameters

- **c** – Takes a pre-initialized checkpoint to prepare
- **t** – A container to restore.
- **ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Returns** prepare\_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore\_checkpoint operation.

`template<typename T, typename ...Ts, typename U = typename std::enable_if<!std::is_same<T,  
checkpoint>::value>::type>`  
`hpx::future<checkpoint> prepare_checkpoint(hpx::launch p, T const &t, Ts const&... ts)`  
 prepare\_checkpoint

prepare\_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore\_checkpoint invocation. prepare\_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

#### Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

#### Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **t** – A container to restore.
- **ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Returns** prepare\_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore\_checkpoint operation.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> prepare_checkpoint(hpx::launch p, checkpoint &&c, T const &t, Ts
const&... ts)
```

#### prepare\_checkpoint

prepare\_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore\_checkpoint invocation. prepare\_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

##### Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

##### Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **c** – Takes a pre-initialized checkpoint to prepare
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** prepare\_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore\_checkpoint operation.

```
template<typename T, typename ...Ts>
void restore_checkpoint(checkpoint const &c, T &t, Ts&... ts)
```

#### Restore\_checkpoint

Restore\_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save\_checkpoint). Restore\_checkpoint can resurrect a stored component in two ways: by passing in a instance of a component's shared\_ptr or by passing in an instance of the component's client.

##### Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

##### Parameters

- **c** – The checkpoint to restore.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Restore\_checkpoint returns void.

## class **checkpoint**

```
#include <checkpoint.hpp> Checkpoint Object
```

Checkpoint is the container object which is produced by save\_checkpoint and is consumed by a restore\_checkpoint. A checkpoint may be moved into the save\_checkpoint object to write the byte stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are able to be serialized including components.

## Public Types

```
using const_iterator = std::vector<char>::const_iterator
```

## Public Functions

```
checkpoint() = default
~checkpoint() = default
checkpoint(checkpoint const &c) = default
checkpoint(checkpoint &&c) noexcept = default
inline checkpoint(std::vector<char> const &vec)
inline checkpoint(std::vector<char> &&vec) noexcept
checkpoint &operator=(checkpoint const &c) = default
checkpoint &operator=(checkpoint &&c) noexcept = default
inline const_iterator begin() const noexcept
inline const_iterator end() const noexcept
inline std::size_t size() const noexcept
inline char *data() noexcept
inline char const *data() const noexcept
```

## Private Functions

```
template<typename Archive>
inline void serialize(Archive &arch, const unsigned int)
```

## Private Members

```
std::vector<char> data_
```

## Friends

```
friend class hpx::serialization::access
friend std::ostream &operator<<(std::ostream &ost, checkpoint const &ckp)
    Operator<< Overload
```

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

**Parameters**

- **ost** – Output stream to write to.
- **ckp** – Checkpoint to copy from.

**Returns** Operator<< returns the ostream object.

```
friend std::istream &operator>>(std::istream &ist, checkpoint &ckp)
```

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

**Parameters**

- **ist** – Input stream to write from.
- **ckp** – Checkpoint to write to.

**Returns** Operator>> returns the ostream object.

```
template<typename T, typename ...Ts>
```

```
friend void restore_checkpoint(checkpoint const &c, T &t, Ts&... ts)
```

Restore\_checkpoint

Restore\_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save\_checkpoint). Restore\_checkpoint can resurrect a stored component in two ways: by passing in a instance of a component's shared\_ptr or by passing in an instance of the component's client.

**Template Parameters**

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

- **c** – The checkpoint to restore.
- **t** – A container to restore.
- **ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Returns** Restore\_checkpoint returns void.

```
inline friend bool operator==(checkpoint const &lhs, checkpoint const &rhs)
```

```
inline friend bool operator!=(checkpoint const &lhs, checkpoint const &rhs)
```

**checkpoint\_base**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

**hpx/checkpoint\_base/checkpoint\_data.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **serialization**

namespace **util**

**Functions**

```
template<typename Container, typename ...Ts>
void save_checkpoint_data(Container &data, Ts&&... ts)
    save_checkpoint_data
```

`Save_checkpoint_data` takes any number of objects which a user may wish to store in the given container.

**Template Parameters**

- **Container** – Container used to store the check-pointed data.
- **Ts** – Types of variables to checkpoint

**Parameters**

- **cont** – Container instance used to store the checkpoint data
- **ts** – Variable instances to be inserted into the checkpoint.

```
template<typename ...Ts>
std::size_t prepare_checkpoint_data(Ts const&... ts)
    prepare_checkpoint_data
```

`prepare_checkpoint_data` takes any number of objects which a user may wish to store in a subsequent `save_checkpoint_data` operation. The function will return the number of bytes necessary to store the data that will be produced.

**Template Parameters** **Ts** – Types of variables to checkpoint**Parameters** **ts** – Variable instances to be inserted into the checkpoint.

```
template<typename Container, typename ...Ts>
void restore_checkpoint_data(Container const &cont, Ts&... ts)
    restore_checkpoint_data
```

`restore_checkpoint_data` takes any number of objects which a user may wish to restore from the given container. The sequence of objects has to correspond to the sequence of objects for the corresponding call to `save_checkpoint_data` that had used the given container instance.

**Template Parameters**

- **Container** – Container used to restore the check-pointed data.

- **Ts** – Types of variables to restore

**Parameters**

- **cont** – Container instance used to restore the checkpoint data
- **ts** – Variable instances to be restored from the container

```
struct checkpointing_tag
```

**collectives**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

**hpx/collectives/all\_gather.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

**Functions**

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> all_gather(char const *basename, T &&result,
                                                     num_sites_arg num_sites = num_sites_arg(),
                                                     this_site_arg this_site = this_site_arg(),
                                                     generation_arg generation = generation_arg(),
                                                     root_site_arg root_site = root_site_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **basename** – The base name identifying the all\_gather operation
- **local\_result** – The value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero. \params root\_site The site that is responsible for creating the all\_gather support object. This value is optional and defaults to ‘0’ (zero).

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> all_gather(communicator comm, T &&result,
                                                       this_site_arg this_site = this_site_arg(),
                                                       generation_arg generation =
                                                       generation_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<std::decay_t<T>>> all_gather(communicator comm, T &&result,
                                         generation_arg generation, this_site_arg
                                         this_site = this_site_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_gather operation has been completed.

## Functions

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> all_reduce(char const *basename, T &&result, F &&op,
                                             num_sites_arg num_sites = num_sites_arg(), this_site_arg
                                             this_site = this_site_arg(), generation_arg generation =
                                             generation_arg(), root_site_arg root_site = root_site_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the all\_reduce operation
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns. \params root\_site The site that is responsible for creating the all\_reduce support object. This value is optional and defaults to '0' (zero).

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> all_reduce(communicator comm, T &&result, F &&op, this_site_arg
                                           this_site = this_site_arg(), generation_arg generation =
                                           generation_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> all_reduce(communicator comm, T &&result, F &&op,
                                             generation_arg generation, this_site_arg this_site =
                                             this_site_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

**hpx/collectives/all\_to\_all.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

**Functions**

```
template<typename T>
hpx::future<std::vector<std::decay_t<T>>> all_to_all(char const *basename, T &&result,
                                                       num_sites_arg num_sites = num_sites_arg(),
                                                       this_site_arg this_site = this_site_arg(),
                                                       generation_arg generation = generation_arg(),
                                                       root_site_arg root_site = root_site_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **basename** – The base name identifying the all\_to\_all operation
- **local\_result** – The value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the all\_to\_all operation performed on the given base name. This is optional and needs to be supplied only if the all\_to\_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns. \params root\_site The site that is responsible for creating the all\_to\_all support object. This value is optional and defaults to ‘0’ (zero).

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_to\_all operation has been completed.

template<typename T>

```
hpx::future<std::vector<std::decay_t<T>>> all_to_all(communicator comm, T &&result,  
this_site_arg this_site = this_site_arg(),  
generation_arg generation =  
generation_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_to\_all operation performed on the given base name. This is optional and needs to be supplied only if the all\_to\_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_to\_all operation has been completed.

```
template<typename T>  
hpx::future<std::vector<std::decay_t<T>>> all_to_all(communicator comm, T &&result,  
generation_arg generation, this_site_arg  
this_site = this_site_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the all\_to\_all operation performed on the given base name. This is optional and needs to be supplied only if the all\_to\_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_to\_all operation has been completed.

## hpx/collectives/barrier.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **distributed**

class **barrier**

`#include <barrier.hpp>` The barrier is an implementation performing a barrier over a number of participating threads. The different threads don't have to be on the same locality. This barrier can be invoked in a distributed application.

For a local only barrier

**See also:**

`hpx::barrier`.

### Public Functions

**barrier**(*std*::string const &*base\_name*)

Creates a barrier, rank is locality id, size is number of localities

A barrier *base\_name* is created. It expects that `hpx::get_num_localities()` participate and the local rank is `hpx::get_locality_id()`.

**Parameters** **base\_name** – The name of the barrier

**barrier**(*std*::string const &*base\_name*, *std*::size\_t *num*)

Creates a barrier with a given size, rank is locality id

A barrier *base\_name* is created. It expects that *num* participate and the local rank is `hpx::get_locality_id()`.

**Parameters**

- **base\_name** – The name of the barrier
- **num** – The number of participating threads

**barrier**(*std*::string const &*base\_name*, *std*::size\_t *num*, *std*::size\_t *rank*)

Creates a barrier with a given size and rank

A barrier *base\_name* is created. It expects that *num* participate and the local rank is *rank*.

**Parameters**

- **base\_name** – The name of the barrier
- **num** – The number of participating threads
- **rank** – The rank of the calling site for this invocation

**barrier**(*std*::string const &*base\_name*, *std*::vector<*std*::size\_t> const &*ranks*, *std*::size\_t *rank*)

Creates a barrier with a vector of ranks

A barrier *base\_name* is created. It expects that `ranks.size()` and the local rank is *rank* (must be contained in *ranks*).

#### Parameters

- **base\_name** – The name of the barrier
- **ranks** – Gives a list of participating ranks (this could be derived from a list of locality ids)
- **rank** – The rank of the calling site for this invocation

`void wait()`

Wait until each participant entered the barrier. Must be called by all participants

**Returns** This function returns once all participants have entered the barrier (have called `wait`).

`hpx::future<void> wait(hpx::launch::async_policy)`

Wait until each participant entered the barrier. Must be called by all participants

**Returns** a future that becomes ready once all participants have entered the barrier (have called `wait`).

## Public Static Functions

`static void synchronize()`

Perform a global synchronization using the default global barrier. The barrier is created once at startup and can be reused throughout the lifetime of an HPX application.

---

**Note:** This function currently does not support dynamic connection and disconnection of localities.

---

## hpx/collectives/broadcast.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

### Functions

```
template<typename T>
hpx::future<void> broadcast_to(char const *basename, T &&local_result, num_sites_arg num_sites =
                                num_sites_arg(), this_site_arg this_site = this_site_arg(),
                                generation_arg generation = generation_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

#### Parameters

- **basename** – The base name identifying the broadcast operation
- **local\_result** – A value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).

- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future that will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<void> broadcast_to(communicator comm, T &&local_result, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future that will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<void> broadcast_to(communicator comm, generation_arg generation, T &&local_result,
    this_site_arg this_site = this_site_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future that will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<T> broadcast_from(char const *basename, this_site_arg this_site = this_site_arg(),
    generation_arg generation = generation_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

**Parameters**

- **basename** – The base name identifying the broadcast operation
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<T> broadcast_from(communicator comm, this_site_arg this_site = this_site_arg(),
                               generation_arg generation = generation_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<T> broadcast_from(communicator comm, generation_arg generation, this_site_arg
                               this_site = this_site_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

## [hpx/collectives/broadcast\\_direct.hpp](#)

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **lcos**

### Functions

```
template<typename Action, typename ArgN, ...
> hpx::future< std::vector< decltype(Action(hpx::id_type, ArgN, ...))>> > broadcast (std::vector< hpx::id_type > const &ids, ArgN argN, ...)
```

Perform a distributed broadcast operation.

The function `hpx::lcos::broadcast` performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

---

**Note:** If `decltype(Action(...))` is void, then the result of this function is `future<void>`.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall reduction operation.

```
template<typename Action, typename ArgN, ...
> void broadcast_apply (std::vector< hpx::id_type > const &ids, ArgN argN, ...)
```

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function `hpx::lcos::broadcast_apply` performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

```
template<typename Action, typename ArgN, ...>
> hpx::future< std::vector< decltype(Action(hpx::id_type, ArgN, ..., std::size_t))> > broadcast_with_index (std::vector< hpx::id_type > const &ids, ArgN argN, ...)
```

Perform a distributed broadcast operation.

The function `hpx::lcos::broadcast_with_index` performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

---

**Note:** If `decltype(Action(...))` is void, then the result of this function is `future<void>`.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall reduction operation.

```
template<typename Action, typename ArgN, ...>
> void broadcast_apply_with_index (std::vector< hpx::id_type > const &ids, ArgN argN, ...)
```

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function `hpx::lcos::broadcast_apply_with_index` performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

## `hpx/collectives/channel_communicator.hpp`

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

### Functions

```
hpx::future<channel_communicator> create_channel_communicator(char const *basename,
                                                               num_sites_arg num_sites =
                                                               num_sites_arg(), this_site_arg
                                                               this_site = this_site_arg())
```

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

#### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future to a new communicator object usable with the collective operation.

```
channel_communicator create_channel_communicator(hpx::launch::sync_policy, char const
                                                 *basename, num_sites_arg num_sites =
                                                 num_sites_arg(), this_site_arg this_site =
                                                 this_site_arg())
```

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

#### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a new communicator object usable with the collective operation.

```
template<typename T>
hpx::future<void> set(channel_communicator comm, that_site_arg site, T &&value, tag_arg tag =
                        tag_arg())
```

Send a value to the given site

This function sends a value to the given site based on the given communicator.

#### Parameters

- **comm** – The channel communicator object to use for the data transfer
- **site** – The destination site
- **value** – The value to send
- **tag** – The (optional) tag identifying the concrete operation

**Returns** This function returns a future<void> that becomes ready once the data transfer operation has finished.

```
template<typename T>
hpx::future<T> get(channel_communicator comm, that_site_arg site, tag_arg tag = tag_arg())
```

Send a value to the given site

This function receives a value from the given site based on the given communicator.

#### Parameters

- **comm** – The channel communicator object to use for the data transfer
- **site** – The source site

**Returns** This function returns a future<T> that becomes ready once the data transfer operation has finished. The future will hold the received value.

## hpx/collectives/communication\_set.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **lcos**

### Functions

```
hpx::future<hpx::id_type> create_communication_set(char const *basename, std::size_t num_sites
= std::size_t(-1), std::size_t this_site =
std::size_t(-1), std::size_t arity =
std::size_t(-1))
```

The function *create\_communication\_set* sets up a (distributed) tree-like communication structure that can be used with any of the collective APIs (such like *all\_to\_all* and similar).

#### Parameters

- **basename** – The base name identifying the all\_to\_all operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **arity** – The number of children each of the communication nodes is connected to (default: picked based on num\_sites)

**Returns** This function returns a future holding an id\_type of the communicator object to be used on the current locality.

## hpx/collectives/create\_communicator.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

## Functions

```
communicator create_communicator(char const *basename, num_sites_arg num_sites =
                                         num_sites_arg(),
                                         this_site_arg this_site = this_site_arg(),
                                         generation_arg generation = generation_arg(),
                                         root_site_arg
                                         root_site = root_site_arg())
```

Create a new communicator object usable with any collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of any of the collective operations (such as *all\_gather*, *all\_reduce*, *all\_to\_all*, *broadcast*, etc.).

### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns. \params *root\_site* The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

**Returns** This function returns a new communicator object usable with the collective operation.

## `hpx/collectives/exclusive_scan.hpp`

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

## Functions

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> exclusive_scan(char const *basename, T &&result, F &&op,
                                         num_sites_arg num_sites = num_sites_arg(),
                                         this_site_arg this_site = this_site_arg(),
                                         generation_arg generation = generation_arg(),
                                         root_site_arg root_site = root_site_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

---

**Note:** The result returned on the *root\_site* is always the same as the result returned on *this\_site == 1* and is the same as the value provided by the *root\_site*.

---

### Parameters

- **basename** – The base name identifying the exclusive\_scan operation

- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the exclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero. \params root\_site The site that is responsible for creating the exclusive\_scan support object. This value is optional and defaults to '0' (zero).

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive\_scan operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> exclusive_scan(communicator comm, T &&result, F &&op,
                                                 this_site_arg this_site = this_site_arg(),
                                                 generation_arg generation = generation_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

---

**Note:** The result returned on the root\_site is always the same as the result returned on thus\_site == 1 and is the same as the value provided by the thje root\_site.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the exclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive\_scan operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> exclusive_scan(communicator comm, T &&result, F &&op,
                                                 generation_arg generation, this_site_arg this_site =
                                                 this_site_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

---

**Note:** The result returned on the root\_site is always the same as the result returned on thus\_site == 1 and is the same as the value provided by the thje root\_site.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the exclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive\_scan operation has been completed.

## hpx/collectives/fold.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **lcos**

### Functions

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...
> hpx::future< decltype(Action(hpx::id_type, ArgN, ...
))> fold (std::vector< hpx::id_type > const &ids, FoldOp &&fold_op, Init &&init,
ArgN argN, ...)
```

Perform a distributed fold operation.

The function hpx::lcos::fold performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall folding operation.

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,
std::size_t))> fold_with_index (std::vector< hpx::id_type > const &ids,
FoldOp &&fold_op, Init &&init, ArgN argN,...)
```

Perform a distributed folding operation.

The function `hpx::lcos::fold_with_index` performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall folding operation.

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,
))> inverse_fold (std::vector< hpx::id_type > const &ids, FoldOp &&fold_op,
Init &&init, ArgN argN,...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall folding operation.

---

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,
std::size_t))> inverse_fold_with_index (std::vector< hpx::id_type > const &ids,
FoldOp &&fold_op, Init &&init, ArgN argN,...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold_with_index` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall folding operation.

## hpx/collectives/gather.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

### Functions

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_here(char const *basename, T &&result,
                                                       num_sites_arg num_sites = num_sites_arg(),
                                                       this_site_arg this_site = this_site_arg(),
                                                       generation_arg generation = generation_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **num\_sites** – The number of participating sites (default: all localities).

- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_here(communicator comm, T &&result, this_site_arg
                                                       this_site = this_site_arg(), generation_arg
                                                       generation = generation_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_here(communicator comm, T &&result,
                                                       generation_arg generation, this_site_arg this_site
                                                       = this_site_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
```

---

```
hpx::future<std::vector<decay_t<T>>> gather_there(char const *basename, T &&result,
                                                       this_site_arg this_site = this_site_arg(),
                                                       generation_arg generation = generation_arg(),
                                                       root_site_arg root_site = root_site_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

**Parameters**

- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

**Returns** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_there(communicator comm, T &&result, this_site_arg
                                                       this_site = this_site_arg(), generation_arg
                                                       generation = generation_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_there(communicator comm, T &&result,
                                                       generation_arg generation, this_site_arg
                                                       this_site = this_site_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

## hpx/collectives/inclusive\_scan.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

### Functions

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> inclusive_scan(char const *basename, T &&result, F &&op,
                                                num_sites_arg num_sites = num_sites_arg(),
                                                this_site_arg this_site = this_site_arg(),
                                                generation_arg generation = generation_arg(),
                                                root_site_arg root_site = root_site_arg())
```

Inclusive inclusive\_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

#### Parameters

- **basename** – The base name identifying the inclusive\_scan operation
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the inclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero. \params root\_site The site that is responsible for creating the inclusive\_scan support object. This value is optional and defaults to ‘0’ (zero).

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive\_scan operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> inclusive_scan(communicator comm, T &&result, F &&op,
                                                this_site_arg this_site = this_site_arg(),
                                                generation_arg generation = generation_arg())
```

Inclusive inclusive\_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the inclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive\_scan operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> inclusive_scan(communicator comm, T &&result, F &&op,
                                                generation_arg generation, this_site_arg this_site =
                                                this_site_arg())
```

Inclusive inclusive\_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the inclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive\_scan operation has been completed.

## hpx/collectives/latch.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **distributed**

```
class latch : public components::client_base<latch, hpx::lcos::server::latch>
```

## Public Functions

**latch()** = default

explicit **latch**(*std*::ptrdiff\_t count)

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter\_ == count.

inline **latch**(*hpx*::id\_type const &id)

Extension: Create a client side representation for the existing *server*::*latch* instance with the given global id *id*.

inline **latch**(*hpx*::*future*<*hpx*::id\_type> &&f)

Extension: Create a client side representation for the existing *server*::*latch* instance with the given global id *id*.

inline **latch**(*hpx*::*shared\_future*<*hpx*::id\_type> const &id)

Extension: Create a client side representation for the existing *server*::*latch* instance with the given global id *id*.

inline **latch**(*hpx*::*shared\_future*<*hpx*::id\_type> &&id)

inline void **count\_down\_and\_wait**()

Decrements counter\_ by 1 . Blocks at the synchronization point until counter\_ reaches 0.

Requires: counter\_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is\_ready calls on this latch that return true.

**Throws** Nothing. –

inline void **arrive\_and\_wait**()

Decrements counter\_ by update . Blocks at the synchronization point until counter\_ reaches 0.

Requires: counter\_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is\_ready calls on this latch that return true.

**Throws** Nothing. –

inline void **count\_down**(*std*::ptrdiff\_t n)

Decrements counter\_ by n. Does not block.

Requires: counter\_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is\_ready calls on this latch that return true .

**Throws** Nothing. –

inline bool **is\_ready**() const noexcept

Returns: counter\_ == 0. Does not block.

**Throws** Nothing. –

inline bool **try\_wait**() const noexcept

Returns: counter\_ == 0. Does not block.

**Throws** Nothing. –

```
inline void wait() const
    If counter_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization
    point until counter_ reaches 0.
    Throws Nothing.
```

## Private Types

`typedef components::client_base<latch, hpx::lcos::server::latch> base_type`

namespace **lcos**

## hpx/collectives/reduce.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

## Functions

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> reduce_here(char const *basename, T &&result, F &&op,
                                              num_sites_arg num_sites = num_sites_arg(), this_site_arg
                                              this_site = this_site_arg(), generation_arg generation =
                                              generation_arg())
```

Reduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the all\_reduce operation
- **local\_result** – A value to reduce on the central reduction point from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

```
template<typename T, typename F>
hpx::future<decay_t<T>> reduce_here(communicator comm, T &&local_result, F &&op,
                                         this_site_arg this_site = this_site_arg(), generation_arg
                                         generation = generation_arg())
```

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to reduce on the root\_site from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

```
template<typename T, typename F>
hpx::future<decay_t<T>> reduce_here(communicator comm, T &&local_result, F &&op,
                                         generation_arg generation, this_site_arg this_site =
                                         this_site_arg())
```

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to reduce on the root\_site from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns** This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

```
template<typename T, typename F>
hpx::future<void> reduce_there(char const *basename, T &&result, this_site_arg this_site =
                                    this_site_arg(), generation_arg generation = generation_arg(),
                                    root_site_arg root_site = root_site_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

**Parameters**

- **basename** – The base name identifying the reduction operation
- **result** – A future referring to the value to transmit to the central reduction point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central reduction point (usually the locality id). This value is optional and defaults to 0.

**Returns** This function returns a future<void>. It will become ready once the reduction operation has been completed.

```
template<typename T>
hpx::future<void> reduce_there(communicator comm, T &&local_result, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to reduce on the central reduction point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

```
template<typename T>
hpx::future<void> reduce_there(communicator comm, T &&local_result, generation_arg generation,
    this_site_arg this_site = this_site_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to reduce on the central reduction point from this call site.
- **generation** – The generational counter identifying the sequence number of the all\_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all\_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns** This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

## `hpx/collectives/reduce_direct.hpp`

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **lcos**

### Functions

```
template<typename Action, typename ReduceOp, typename ArgN, ...
> hpx::future< decltype(Action(hpx::id_type, ArgN, ...
))> reduce (std::vector< hpx::id_type > const &ids, ReduceOp &&reduce_op,
ArgN argN,...)
```

Perform a distributed reduction operation.

The function `hpx::lcos::reduce` performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **reduce\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall reduction operation.

```
template<typename Action, typename ReduceOp, typename ArgN, ...>
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,
std::size_t))> reduce_with_index (std::vector< hpx::id_type > const &ids,
ReduceOp &&reduce_op, ArgN argN,...)
```

Perform a distributed reduction operation.

The function `hpx::lcos::reduce_with_index` performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **reduce\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**Returns** This function returns a future representing the result of the overall reduction operation.

## hpx/collectives/scatter.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **collectives**

### Functions

```
template<typename T>
hpx::future<T> scatter_from(char const *basename, this_site_arg this_site = this_site_arg(),
                             generation_arg generation = generation_arg(), root_site_arg root_site =
                             root_site_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

#### Parameters

- **basename** – The base name identifying the scatter operation
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

**Returns** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_from(communicator comm, this_site_arg this_site = this_site_arg(),
                             generation_arg generation = generation_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_from(communicator comm, generation_arg generation, this_site_arg this_site
                           = this_site_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_to(char const *basename, std::vector<T> &&result, num_sites_arg num_sites
                           = num_sites_arg(), this_site_arg this_site = this_site_arg(), generation_arg
                           generation = generation_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

#### Parameters

- **basename** – The base name identifying the scatter operation
- **result** – The value to transmit to the central scatter point from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_to(communicator comm, std::vector<T> &&result, this_site_arg this_site =
                           this_site_arg(), generation_arg generation = generation_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_to(communicator comm, std::vector<T> &&result, generation_arg
                           generation, this_site_arg this_site = this_site_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed

more than once. The generation number (if given) must be a positive number greater than zero.

- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get\_locality\_id() returns.

**Returns** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

## components

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/components/basename\_registration.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Functions

```
template<typename Client>
std::vector<Client> find_all_from_basename(std::string base_name, std::size_t num_ids)
```

Return all registered clients from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered ids from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

---

**Note:** The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

**Note:** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

**Template Parameters** **Client** – The client type to return

#### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **num\_ids** – [in] The number of registered ids to expect.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **num\_ids** – [in] The number of registered ids to expect.

**Returns** A list of futures representing the ids which were registered using the given base name.

**Returns** A list of futures representing the ids which were registered using the given base name.

```
template<typename Client>
std::vector<Client> find_from_basename(std::string base_name, std::vector<std::size_t> const &ids)
```

Return registered clients from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return registered ids from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

---

**Note:** The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

---

**Note:** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

**Template Parameters** `Client` – The client type to return

#### Parameters

- `base_name` – [in] The base name for which to retrieve the registered ids.
- `ids` – [in] The sequence numbers of the registered ids.
- `base_name` – [in] The base name for which to retrieve the registered ids.
- `ids` – [in] The sequence numbers of the registered ids.

**Returns** A list of futures representing the ids which were registered using the given base name and sequence numbers.

**Returns** A list of futures representing the ids which were registered using the given base name and sequence numbers.

```
template<typename Client>
```

```
Client find_from_basename(std::string base_name, std::size_t sequence_nr)
```

Return registered id from the given base name and sequence number.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

---

**Note:** The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

---

**Note:** The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

**Template Parameters** **Client** – The client type to return

**Parameters**

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in] The sequence number of the registered id.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in] The sequence number of the registered id.

**Returns** A representing the id which was registered using the given base name and sequence numbers.

**Returns** A representing the id which was registered using the given base name and sequence numbers.

```
template<typename Client, typename Stub>
hpx::future<bool> register_with_basename(std::string base_name, components::client_base<Client,
                                           Stub> &client, std::size_t sequence_nr)
```

Register the id wrapped in the given client using the given base name.

The function registers the object the given client refers to using the provided base name.

---

**Note:** The operation will fail if the given sequence number is not unique.

---

**Template Parameters** **Client** – The client type to register

**Parameters**

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **client** – [in] The client which should be registered using the given base name.
- **sequence\_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

**Returns** A future representing the result of the registration operation itself.

```
template<typename Client>
Client unregister_with_basename(std::string base_name, std::size_t sequence_nr =
                                ~static_cast<std::size_t>(0))
```

Unregister the given id using the given base name.

Unregister the given base name.

The function unregisters the given ids using the provided base name.

The function unregisters the given ids using the provided base name.

**Template Parameters** **Client** – The client type to return

#### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register\_with\_basename* before.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register\_with\_basename* before.

**Returns** A future representing the result of the un-registration operation itself.

**Returns** A future representing the result of the un-registration operation itself.

## hpx/components basename\_registration\_fwd.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
hpx::future<bool> register_with_basename(std::string base_name, hpx::id_type id, std::size_t  
sequence_nr = ~static_cast<std::size_t>(0))
```

Register the given id using the given base name.

The function registers the given ids using the provided base name.

---

**Note:** The operation will fail if the given sequence number is not unique.

---

#### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **id** – [in] The id to register using the given base name.
- **sequence\_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

**Returns** A future representing the result of the registration operation itself.

```
hpx::future<bool> register_with_basename(std::string base_name, hpx::future<hpx::id_type> f,
                                         std::size_t sequence_nr = ~static_cast<std::size_t>(0))
```

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

---

**Note:** The operation will fail if the given sequence number is not unique.

---

### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **f** – [in] The future which should be registered using the given base name.
- **sequence\_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

**Returns** A future representing the result of the registration operation itself.

## hpx/components/components\_fwd.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

```
template<typename Derived, typename Stub>
```

```
class client_base
```

namespace **components**

## hpx/components/get\_ptr.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename Component>
hpx::future<std::shared_ptr<Component>> get_ptr(hpx::id_type const &id)
```

Returns a future referring to the pointer to the underlying memory of a component.

The function `hpx::get_ptr` can be used to extract a future referring to the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

**Parameters** `id` – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

**Template Parameters** `The` – only template parameter has to be the type of the server side component.

**Returns** This function returns a future representing the pointer to the underlying memory for the component instance with the given `id`.

```
template<typename Derived, typename Stub>
hpx::future<std::shared_ptr<typename components::client_base<Derived, Stub>::server_component_type>> get_ptr(components::client_base<Derived, Stub>::server_component_type const &c)
```

Returns a future referring to the pointer to the underlying memory of a component.

The function `hpx::get_ptr` can be used to extract a future referring to the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

**Parameters** `c` – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

**Returns** This function returns a future representing the pointer to the underlying memory for the component instance with the given `id`.

```
template<typename Component>
std::shared_ptr<Component> get_ptr(launch::sync_policy p, hpx::id_type const &id, error_code &ec = throws)
```

Returns the pointer to the underlying memory of a component.

The function `hpx::get_ptr_sync` can be used to extract the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise an error.

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

### Parameters

- **p** – [in] The parameter `p` represents a placeholder type to turn make the call synchronous.
- **id** – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Template Parameters** **The** – only template parameter has to be the type of the server side component.

**Returns** This function returns the pointer to the underlying memory for the component instance with the given `id`.

```
template<typename Derived, typename Stub>
std::shared_ptr<typename components::client_base<Derived, Stub>::server_component_type> get_ptr(launch::sync_policy
p,
com-
po-
nents::client_base<Der-
Stub>
const
&c,
er-
ror_code
&ec
=
throws)
```

Returns the pointer to the underlying memory of a component.

The function `hpx::get_ptr_sync` can be used to extract the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently

---

located on the requesting locality. Otherwise the function will raise an error.

---

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared\_ptr alive.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

### Parameters

- **p** – [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- **c** – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function returns the pointer to the underlying memory for the component instance with the given *id*.

## hpx/components\_base/component\_commandline.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

```
HPX_DEFINE_COMPONENT_COMMANDLINE_OPTIONS(add_options_function)
```

```
HPX_REGISTER_COMMANDLINE_MODULE(add_options_function)
```

```
HPX_REGISTER_COMMANDLINE_MODULE_DYNAMIC(add_options_function)
```

namespace **hpx**

namespace **components**

```
struct component_commandline : public component_commandline_base
```

```
#include <component_commandline.hpp> The component_startup_shutdown provides a minimal implementation of a component's startup/shutdown function provider.
```

## Public Functions

inline `hpx::program_options::options_description add_commandline_options()` override  
 Return any additional command line options valid for this component.

---

**Note:** This function will be executed by the runtime system during system startup.

---

**Returns** The module is expected to fill a `options_description` object with any additional command line options this component will handle.

namespace `commandline_options_provider`

## Functions

`hpx::program_options::options_description add_commandline_options()`

### `hpx/components_base/component_startup_shutdown.hpp`

See *Public API* for a list of names and headers that are part of the public HPX API.

## Defines

```
HPX_DEFINE_COMPONENT_STARTUP_SHUTDOWN(startup_, shutdown_)

HPX_REGISTER_STARTUP_SHUTDOWN_MODULE_(startup, shutdown)
HPX_REGISTER_STARTUP_SHUTDOWN_MODULE_(startup, shutdown)
HPX_REGISTER_STARTUP_SHUTDOWN_MODULE_DYNAMIC_(startup, shutdown)
HPX_REGISTER_STARTUP_MODULE_(startup)
HPX_REGISTER_STARTUP_MODULE_DYNAMIC_(startup)
HPX_REGISTER_SHUTDOWN_MODULE_(shutdown)
HPX_REGISTER_SHUTDOWN_MODULE_DYNAMIC_(shutdown)
```

namespace `hpx`

namespace `components`

```
template<bool (*Startup)(startup_function_type&, bool&), bool
        (*Shutdown)(shutdown_function_type&, bool&)>
struct component_startup_shutdown : public component_startup_shutdown_base
```

`#include <component_startup_shutdown.hpp>` The `component_startup_shutdown` class provides a minimal implementation of a component's startup/shutdown function provider.

## Public Functions

```
inline bool get_startup_function(startup_function_type &startup, bool &pre_startup) override
```

Return any startup function for this component.

**Parameters** **startup** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

**Returns** Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

```
inline bool get_shutdown_function(shutdown_function_type &shutdown, bool &pre_shutdown) override
```

Return any shutdown function for this component.

**Parameters** **shutdown** – [in, out] The module is expected to fill this function object with a reference to a shutdown function. This function will be executed by the runtime system during system shutdown.

**Returns** Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

```

```
util::atomic_count &instance_count(component_type type)
```

```
component_deleter_type &deleter(component_type type)
```

```
bool enumerate_instance_counts(hpx::move_only_function<bool(component_type)> const &f)
```

```
const std::string get_component_type_name(component_type type)
```

Return the string representation for a given component type id.

```
inline constexpr component_type get_base_type(component_type t) noexcept
```

The lower short word of the component type is the type of the component exposing the actions.

```
inline constexpr component_type get_derived_type(component_type t) noexcept
```

The upper short word of the component is the actual component type.

```
inline constexpr component_type derived_component_type(component_type derived,  
component_type base) noexcept
```

A component derived from a base component exposing the actions needs to have a specially formatted component type.

```
inline constexpr bool types_are_compatible(component_type lhs, component_type rhs) noexcept
```

Verify the two given component types are matching (compatible)

```
template<typename Component, typename Enable = void>  
constexpr char const *get_component_name() noexcept
```

```
template<typename Component, typename Enable = void>  
constexpr const char *get_component_base_name() noexcept

```
template<typename Component>  
inline void set_component_type(component_type type)
```

namespace **naming**

## Functions

```
std::ostream &operator<<(std::ostream&, address const&)
```

### hpx/components\_base/components\_base\_fwd.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

## TypeDefs

```
typedef component<Component> instead
template<typename Component = detail::this_type>
class abstract_component_base
template<typename Component, typename Derived = detail::this_type>
class abstract_managed_component_base
template<typename Component>
class component
template<typename Component = detail::this_type>
class component_base
template<typename Component>
class fixed_component
template<typename Component>
class fixed_component_base
template<typename Component, typename Derived>
class managed_component
```

#include <managed\_component\_base.hpp> The `managed_component` template is used as a indirection layer for components allowing to gracefully handle the access to non-existing components.

Additionally it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a `managed_component` gets assigned a global id. The provided memory management allocates the `managed_component` instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.

### Template Parameters

- **Component** –
- **Derived** –

```
template<typename Component, typename Wrapper, typename CtorPolicy, typename DtorPolicy>
class managed_component_base

namespace components
```

### hpx/components\_base/get\_lva.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace hpx

```
template<typename Component, typename Enable = void>
```

```
struct get_lva
```

`#include <get_lva.hpp>` The `get_lva` template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function `resolver_client::resolve`) to the address of the component implementing the action.

The default implementation uses the template argument `Component` to deduce the type wrapping the component implementing the action. This is used to get the needed address.

**Template Parameters** `Component` – This is the type of the component implementing the action to execute.

### Public Static Functions

```
static inline constexpr Component *call(naming::address_type lva) noexcept
```

### hpx/components\_base/server/fixed\_component\_base.hpp

## hpx/distribution\_policies/binpacking\_distribution\_policy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

## Variables

```
constexpr char const *const default_binpacking_counter_name =
"/runtime{locality/total}/count/component@"
```

```
static const binpacking_distribution_policy binpacked = {}
```

A predefined instance of the binpacking *distribution\_policy*. It will represent the local locality and will place all items to create here.

```
struct binpacking_distribution_policy
```

*#include <binpacking\_distribution\_policy.hpp>* This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).

## Public Functions

```
inline binpacking_distribution_policy()
```

Default-construct a new instance of a *binpacking\_distribution\_policy*. This policy will represent one locality (the local locality).

```
inline binpacking_distribution_policy operator() (std::vector<id_type> const &locs, char const
                                                 *perf_counter_name =
                                                 default_binpacking_counter_name) const
```

Create a new *default\_distribution* policy representing the given set of localities.

### Parameters

- **locs** – [in] The list of localities the new instance should represent
- **perf\_counter\_name** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

```
inline binpacking_distribution_policy operator() (std::vector<id_type> &&locs, char const
                                                 *perf_counter_name =
                                                 default_binpacking_counter_name) const
```

Create a new *default\_distribution* policy representing the given set of localities.

### Parameters

- **locs** – [in] The list of localities the new instance should represent
- **perf\_counter\_name** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

```
inline binpacking_distribution_policy operator() (id_type const &loc, char const
                                                 *perf_counter_name =
                                                 default_binpacking_counter_name) const
```

Create a new *default\_distribution* policy representing the given locality

### Parameters

- **loc** – [in] The locality the new instance should represent
- **perf\_counter\_name** – [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

```
template<typename Component, typename ...Ts>
inline hpx::future<hpx::id_type> create(Ts&&... vs) const
    Create one object on one of the localities associated by this policy instance
    Parameters vs – [in] The arguments which will be forwarded to the constructor of the new
        object.
    Returns A future holding the global address which represents the newly created object

template<typename Component, typename ...Ts>
inline hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs)
    const
    Create multiple objects on the localities associated by this policy instance
    Parameters
        • count – [in] The number of objects to create
        • vs – [in] The arguments which will be forwarded to the constructors of the new objects.
    Returns A future holding the list of global addresses which represent the newly created
        objects

inline std::string const &get_counter_name() const
    Returns the name of the performance counter associated with this policy instance.

inline std::size_t get_num_localities() const
    Returns the number of associated localities for this distribution policy
```

---

**Note:** This function is part of the creation policy implemented by this class

---

## hpx/distribution\_policies/colocating\_distribution\_policy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

### Variables

```
static const colocating_distribution_policy colocated = {}
```

A predefined instance of the co-locating *distribution\_policy*. It will represent the local locality and will place all items to create here.

```
struct colocating_distribution_policy
```

```
#include <colocating_distribution_policy.hpp> This class specifies the parameters for a distribution
policy to use for creating a given number of items on the locality where a given object is currently
placed.
```

## Public Functions

**colocating\_distribution\_policy()** = default

Default-construct a new instance of a `colocating_distribution_policy`. This policy will represent the local locality.

inline `colocating_distribution_policy operator()(id_type const &id)` const

Create a new `colocating_distribution_policy` representing the locality where the given object is current located

**Parameters** `id` – [in] The global address of the object with which the new instances should be colocated on

template<typename **Client**, typename **Stub**>

inline `colocating_distribution_policy operator()(client_base<Client, Stub> const &client)` const

Create a new `colocating_distribution_policy` representing the locality where the given object is current located

**Parameters** `client` – [in] The client side representation of the object with which the new instances should be colocated on

template<typename **Component**, typename ...**Ts**>

inline `hpx::future<hpx::id_type> create(Ts&&... vs)` const

Create one object on the locality of the object this distribution policy instance is associated with

**Note:** This function is part of the placement policy implemented by this class

**Parameters** `vs` – [in] The arguments which will be forwarded to the constructor of the new object.

**Returns** A future holding the global address which represents the newly created object

template<typename **Component**, typename ...**Ts**>

inline `hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs)` const

Create multiple objects colocated with the object represented by this policy instance

**Note:** This function is part of the placement policy implemented by this class

### Parameters

- `count` – [in] The number of objects to create
- `vs` – [in] The arguments which will be forwarded to the constructors of the new objects.

**Returns** A future holding the list of global addresses which represent the newly created objects

template<typename **Action**, typename ...**Ts**>

inline `async_result<Action>::type async(launch policy, Ts&&... vs)` const

template<typename **Action**, typename **Callback**, typename ...**Ts**>

inline `async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs)` const

**Note:** This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Continuation**, typename ...**Ts**>

```
inline bool apply(Continuation &&c, threads::thread_priority priority, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename ...Ts>
```

```
inline bool apply(threads::thread_priority priority, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(Continuation &&c, threads::thread_priority priority, Callback &&cb,  
                     Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(threads::thread_priority priority, Callback &&cb, Ts&&... vs) const
```

```
inline std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy

---

**Note:** This function is part of the creation policy implemented by this class

---

```
inline hpx::id_type get_next_target() const
```

Returns the locality which is anticipated to be used for the next async operation

```
template<typename Action>
```

```
struct async_result
```

```
#include <colocating_distribution_policy.hpp>
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

## Public Types

```
using type = hpx::future<typename traits::promise_local_result<typename  
                           hpx::traits::extract_action<Action>::remote_result_type>::type>
```

## [hpx/distribution\\_policies/target\\_distribution\\_policy.hpp](#)

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

## Variables

```
static const target_distribution_policy target = {}
```

A predefined instance of the *target\_distribution\_policy*. It will represent the local locality and will place all items to create here.

```
struct target_distribution_policy
```

*#include <target\_distribution\_policy.hpp>* This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

## Public Functions

```
target_distribution_policy() = default
```

Default-construct a new instance of a *target\_distribution\_policy*. This policy will represent one locality (the local locality).

```
inline target_distribution_policy operator()(id_type const &id) const
```

Create a new *target\_distribution\_policy* representing the given locality

**Parameters** **loc** – [in] The locality the new instance should represent

```
template<typename Component, typename ...Ts>
```

```
inline hpx::future<hpx::id_type> create(Ts&&... vs) const
```

Create one object on one of the localities associated by this policy instance

**Note:** This function is part of the placement policy implemented by this class

**Parameters** **vs** – [in] The arguments which will be forwarded to the constructor of the new object.

**Returns** A future holding the global address which represents the newly created object

```
template<typename Component, typename ...Ts>
```

```
inline hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs) const
```

Create multiple objects on the localities associated by this policy instance

**Note:** This function is part of the placement policy implemented by this class

### Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

**Returns** A future holding the list of global addresses which represent the newly created objects

```
template<typename Action, typename ...Ts>
```

```
inline async_result<Action>::type async(launch policy, Ts&&... vs) const
```

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

**Note:** This function is part of the invocation policy implemented by this class

```
template<typename Action, typename Continuation, typename ...Ts>
inline bool apply(Continuation &&c, threads::thread_priority priority, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename ...Ts>
inline bool apply(threads::thread_priority priority, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename Callback, typename ...Ts>
inline bool apply_cb(Continuation &&c, threads::thread_priority priority, Callback &&cb,
                    Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Callback, typename ...Ts>
inline bool apply_cb(threads::thread_priority priority, Callback &&cb, Ts&&... vs) const
```

```
inline std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy

---

**Note:** This function is part of the creation policy implemented by this class

---

```
inline hpx::id_type get_next_target() const
```

Returns the locality which is anticipated to be used for the next async operation

```
template<typename Action>
```

```
struct async_result
```

```
#include <target_distribution_policy.hpp>
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

## Public Types

```
struct unwrapping_result_policy
```

`#include <unwrapping_result_policy.hpp>` This class is a distribution policy that can be using with actions that return futures. For those actions it is possible to apply certain optimizations if the action is invoked synchronously.

## Public Functions

```
inline explicit unwrapping_result_policy(id_type const &id)
```

```
template<typename Client, typename Stub>
```

```
inline explicit unwrapping_result_policy(client_base<Client, Stub> const &client)
```

```
template<typename Action, typename ...Ts>
```

```
inline async_result<Action>::type async(launch policy, Ts&&... vs) const
```

```
template<typename Action, typename ...Ts>
```

```
inline async_result<Action>::type async(launch::sync_policy, Ts&&... vs) const
```

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename ...Ts>
```

```
inline bool apply(Continuation &&c, threads::thread_priority priority, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

```
template<typename Action, typename ...Ts>
```

```
inline bool apply(threads::thread_priority priority, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(Continuation &&c, threads::thread_priority priority, Callback &&cb,
                     Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(threads::thread_priority priority, Callback &&cb, Ts&&... vs) const
```

```
inline hpx::id_type const &get_next_target() const
```

```
template<typename Action>

## Functions

```
template<typename DistPolicy>
distribution_policy_executor<typename std::decay<DistPolicy>::type> make_distribution_policy_executor(DistPolicy const& policy);
```

Create a new *distribution\_policy\_executor* from the given distribution\_policy.

**Parameters** `policy` – The distribution\_policy to create an executor from

```
template<typename DistPolicy>
```

```
class distribution_policy_executor
```

```
#include <distribution_policy_executor.hpp> A distribution_policy_executor creates groups of parallel execution agents which execute in threads implicitly created by the executor and placed on any of the associated localities.
```

**Template Parameters `DistPolicy`** – The distribution policy type for which an executor should be created. The expression `hpx::traits::is_distribution_policy<DistPolicy>::value` must evaluate to true.

## Public Functions

```
template<typename DistPolicy_, typename Enable = typename  
std::enable_if<!std::is_same<distribution_policy_executor, typename  
std::decay<DistPolicy_>::type>::value>::type>  
inline distribution_policy_executor(DistPolicy_ &&policy)
```

Create a new distribution\_policy executor from the given distribution policy  
**Parameters** `policy` – The distribution\_policy to create an executor from

namespace **hpx**

#### Functions

int **finalize**(double shutdown\_timeout, double localwait = -1.0, *error\_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function *hpx::finalize* is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on all localities.

The default value (-1.0) will try to find a globally set timeout value (can be set as the configuration parameter *hpx.shutdown\_timeout*), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter “*hpx.finalize\_wait\_time*”), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Using this function is an alternative to *hpx::disconnect*, these functions do not need to be called both.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn’t throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

#### Parameters

- **shutdown\_timeout** – This parameter allows to specify a timeout (in microseconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **localwait** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function will always return zero.

```
inline int finalize(error_code &ec = throws)
```

Main function to gracefully terminate the HPX runtime system.

The function *hpx::finalize* is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on all localities.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Using this function is an alternative to *hpx::disconnect*, these functions do not need to be called both.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function will always return zero.

```
void terminate()
```

Terminate any application non-gracefully.

The function *hpx::terminate* is the non-graceful way to exit any application immediately. It can be called from any locality and will terminate all localities currently used by the application.

---

**Note:** This function will cause HPX to call *std::terminate()* on all localities associated with this application. If the function is called not from an HPX thread it will fail and return an error using the argument *ec*.

---

```
int disconnect(double shutdown_timeout, double localwait = -1.0, error_code &ec = throws)
```

Disconnect this locality from the application.

The function *hpx::disconnect* can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on this locality.

---

The default value (-1.0) will try to find a globally set timeout value (can be set as the configuration parameter “`hpx.shutdown_timeout`”), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter `hpx.finalize_wait_time`), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

### Parameters

- **shutdown\_timeout** – This parameter allows to specify a timeout (in microseconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **localwait** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function will always return zero.

inline int **disconnect**(*error\_code* &`ec` = `throws`)

Disconnect this locality from the application.

The function `hpx::disconnect` can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on this locality.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function will always return zero.

```
int stop(error_code &ec = throws)
```

Stop the runtime system.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called on every locality. This function should be used only if the runtime system was started using `hpx::start`.

**Returns** The function returns the value, which has been returned from the user supplied main HPX function (usually `hpx_main`).

## hpx/hpx\_init.hpp

### Functions

```
inline int init(std::function<int(hpx::program_options::variables_map&)> f, int argc, char **argv,  
               init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

---

**Note:** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise it will be executed as specified by the `parametemode`.

---

### Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).

- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

**Returns** The function returns the value, which has been returned from the user supplied `f`.

```
inline int init(std::function<int(int, char**) > f, int argc, char **argv, init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

**Returns** The function returns `true` if command line processing succeeded and the runtime system was started successfully. It will return `false` otherwise.

## hpx/hpx\_suspend.hpp

See [Public API](#) for a list of names and headers that are part of the public *HPX API*.

namespace **hpx**

### Functions

int **suspend**(*error\_code* &ec = *throws*)

Suspend the runtime system.

The function `hpx::suspend` is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** This function will always return zero.

int **resume**(*error\_code* &ec = *throws*)

Resume the HPX runtime system.

The function `hpx::resume` is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** This function will always return zero.

## naming\_base

See *Public API* for a list of names and headers that are part of the public HPX API.

### **hpx/naming\_base/unmanaged.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **naming**

#### Functions

*hpx::id\_type unmanaged(hpx::id\_type const &id)*

The helper function *hpx::unmanaged* can be used to generate a global identifier which does not participate in the automatic garbage collection.

---

**Note:** This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

---

**Parameters** **id** – [in] The id to generated the unmanaged global id from This parameter can be itself a managed or a unmanaged global id.

**Returns** This function returns a new global id referencing the same object as the parameter *id*. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

## parcels

See *Public API* for a list of names and headers that are part of the public HPX API.

## hpx/parcelset/connection\_cache.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **parcelset**

### TypeDefs

```
using parcel_write_handler_type = hpx::function<void(std::error_code const&, parcelset::parcel const&)>
```

The type of a function that can be registered as a parcel write handler using the function *hpx::set\_parcel\_write\_handler*.

---

**Note:** A parcel write handler is a function which is called by the parcel layer whenever a parcel has been sent by the underlying networking library and if no explicit parcel handler function was specified for the parcel.

---

## Enums

enum **parcelport\_background\_mode**

Type of background work to perform.

*Values:*

enumerator **parcelport\_background\_mode\_flush\_buffers**

perform buffer flush operations

enumerator **parcelport\_background\_mode\_send**

perform send operations (includes buffer flush)

enumerator **parcelport\_background\_mode\_receive**

perform receive operations

enumerator **parcelport\_background\_mode\_all**

perform all operations

## hpx/parcelset\_base/set\_parcel\_write\_handler.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## performance\_counters

See [Public API](#) for a list of names and headers that are part of the public HPX API.

## hpx/performance\_counters/counter\_creators.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **performance\_counters**

## Functions

bool **default\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&,  
*discover\_counters\_mode*, *error\_code*&)

Default discovery function for performance counters; to be registered with the counter types. It will pass the *counter\_info* and the *error\_code* to the supplied function.

bool **locality\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&,  
*discover\_counters\_mode*, *error\_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality\_id>/total)/<instancename>

---

```
bool locality_pool_counter_discoverer(counter_info const&, discover_counter_func const&,
                                         discover_counters_mode, error_code&)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>(locality#<locality_id>/pool#<pool_name>/total)/<instancename>
```

```
bool locality0_counter_discoverer(counter_info const&, discover_counter_func const&,
                                         discover_counters_mode, error_code&)
```

Default discoverer function for AGAS performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>{locality#0/total}/<instancename>
```

```
bool locality_thread_counter_discoverer(counter_info const&, discover_counter_func const&,
                                         discover_counters_mode, error_code&)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>(locality#<locality_id>/worker-thread#<threadnum>)/<instancename>
```

```
bool locality_pool_thread_counter_discoverer(counter_info const &info,
                                               discover_counter_func const &f,
                                               discover_counters_mode mode, error_code
                                               &ec)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>{locality#<locality_id>/pool#<poolname>/thread#<threadnum> }/<instancename>
```

```
bool locality_pool_thread_no_total_counter_discoverer(counter_info const &info,
                                                       discover_counter_func const &f,
                                                       discover_counters_mode mode,
                                                       error_code &ec)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>{locality#<locality_id>/pool#<poolname>/thread#<threadnum> }/<instancename>
```

This is essentially the same as above just that locality#\*/total is not supported.

```
bool locality numa_counter_discoverer(counter_info const&, discover_counter_func const&,
                                         discover_counters_mode, error_code&)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>(locality#<locality_id>/numa-node#<threadnum>)/<instancename>
```

```
naming::gid_type locality_raw_counter_creator(counter_info const&,
                                                 hpx::function<std::int64_t(bool)> const&,
                                                 error_code&)
```

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

```
/<objectname>(locality#<locality_id>/total)/<instancename>
```

```
naming::gid_type locality_raw_values_counter_creator(counter_info const&,
                                                       hpx::function<std::vector<std::int64_t>(bool)>
                                                       const&, error_code&)
```

*naming*::gid\_type **agas\_raw\_counter\_creator**(*counter\_info* const&, *error\_code*&, char const\*const)

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

/agas(<objectinstance>/total)/<instancename>

bool **agas\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&,  
*discover\_counters\_mode*, *error\_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/agas(<objectinstance>/total)/<instancename>

*naming*::gid\_type **local\_action\_invocation\_counter\_creator**(*counter\_info* const&,  
*error\_code*&)

bool **local\_action\_invocation\_counter\_discoverer**(*counter\_info* const&,  
*discover\_counter\_func* const&,  
*discover\_counters\_mode*, *error\_code*&)

## hpx/performance\_counters/counters.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **performance\_counters**

### Typedefs

typedef *hpx*::function<*naming*::gid\_type(*counter\_info* const&, *error\_code*&)> **create\_counter\_func**

This declares the type of a function, which will be called by HPX whenever a new performance counter instance of a particular type needs to be created.

typedef *hpx*::function<bool(*counter\_info* const&, *error\_code*&)> **discover\_counter\_func**

This declares a type of a function, which will be passed to a *discover\_counters\_func* in order to be called for each discovered performance counter instance.

typedef *hpx*::function<bool(*counter\_info* const&, *discover\_counter\_func* const&,  
*discover\_counters\_mode*, *error\_code*&)> **discover\_counters\_func**

This declares the type of a function, which will be called by HPX whenever it needs to discover all performance counter instances of a particular type.

## Enums

enum class **counter\_type**

*Values:*

enumerator **text**

*text* shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

enumerator **raw**

*raw* shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

enumerator **monotonically\_increasing**

*monotonically\_increasing* shows the cumulatively accumulated observed value. It does not deliver an average.

Formula: None. Shows cumulatively accumulated data as collected. Average: None Type: Instantaneous

enumerator **average\_base**

*average\_base* is used as the base data (denominator) in the computation of time or count averages for the *counter\_type::average\_count* and *counter\_type::average\_timer* counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factorial calculations without delivering an output.  
Average:  $\text{SUM } (N) / x$  Type: Instantaneous

enumerator **average\_count**

*average\_count* shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula:  $(N_1 - N_0) / (D_1 - D_0)$ , where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average:  $(N_x - N_0) / (D_x - D_0)$  Type: Average

enumerator **aggregating**

*aggregating* applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula:  $F(N_x)$

enumerator **average\_timer**

*average\_timer* measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula:  $((N1 - N0) / F) / (D1 - D0)$ , where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval.  
Average:  $((Nx - N0) / F) / (Dx - D0)$  Type: Average

#### enumerator **elapsed\_time**

*elapsed\_time* shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula:  $(D0 - N0) / F$ , where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average:  $(Dx - N0) / F$  Type: Difference

#### enumerator **histogram**

*histogram* exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

#### enumerator **raw\_values**

*raw\_values* exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.

#### enumerator **text**

#### enumerator **raw**

#### enumerator **monotonically\_increasing**

#### enumerator **average\_base**

#### enumerator **average\_count**

#### enumerator **aggregating**

#### enumerator **average\_timer**

#### enumerator **elapsed\_time**

#### enumerator **histogram**

**enumerator `raw_values`**

*raw\_values* counter exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a `counter_value_array` instead of a `counter_value`. Those will also not implement the `get_counter_value()` functionality. The results are exposed through a separate `get_counter_values_array()` function.

**enum class `counter_status`**

Status and error codes used by the functions related to performance counters.

*Values:*

**enumerator `valid_data`**

No error occurred, data is valid.

**enumerator `new_data`**

Data is valid and different from last call.

**enumerator `invalid_data`**

Some error occurred, data is not value.

**enumerator `already_defined`**

The type or instance already has been defined.

**enumerator `counter_unknown`**

The counter instance is unknown.

**enumerator `counter_type_unknown`**

The counter type is unknown.

**enumerator `generic_error`**

A unknown error occurred.

**enumerator `valid_data`****enumerator `new_data`****enumerator `invalid_data`****enumerator `already_defined`****enumerator `counter_unknown`****enumerator `counter_type_unknown`****enumerator `generic_error`**

## Functions

```
inline std::string &ensure_counter_prefix(std::string &name)
inline std::string ensure_counter_prefix(std::string const &counter)
inline std::string &remove_counter_prefix(std::string &name)
inline std::string remove_counter_prefix(std::string const &counter)
char const *get_counter_type_name(counter_type state)
    Return the readable name of a given counter type.
inline bool status_is_valid(counter_status s)
inline counter_status add_counter_type(counter_info const &info, error_code &ec)
inline hpx::id_type get_counter(std::string const &name, error_code &ec)
inline hpx::id_type get_counter(counter_info const &info, error_code &ec)
```

## Variables

```
constexpr const char counter_prefix[] = "/counters"
constexpr std::size_t counter_prefix_len = (sizeof(counter_prefix) / sizeof(counter_prefix[0])) - 1
struct counter_info
```

## Public Functions

```
inline counter_info(counter_type type = counter_type::raw)
inline counter_info(std::string const &name)
inline counter_info(counter_type type, std::string const &name, std::string const &helptext = "",  
    std::uint32_t version = HPX_PERFORMANCE_COUNTER_V1, std::string  
    const &uom = "")
```

## Public Members

*counter\_type* **type\_**

The type of the described counter.

*std*::uint32\_t **version\_**

The version of the described counter using the 0xMMmmSSSS scheme

*counter\_status* **status\_**

The status of the counter object.

`std::string fullname_`

The full name of this counter.

`std::string helptext_`

The full descriptive text for this counter.

`std::string unit_of_measure_`

The unit of measure for this counter.

## Private Functions

## Functions

inline constexpr bool **operator<(counter\_type lhs, counter\_type rhs)** noexcept

inline constexpr bool **operator>(counter\_type lhs, counter\_type rhs)** noexcept

inline *std*::ostream &**operator<<(std::ostream &os, counter\_status const &rhs)** noexcept

*counter\_status* **get\_counter\_type\_name(counter\_type\_path\_elements const &path, std::string &result, error\_code &ec = throws)**

Create a full name of a counter type from the contents of the given *counter\_type\_path\_elements* instance. The generated counter type name will not contain any parameters.

*counter\_status* **get\_full\_counter\_type\_name(counter\_type\_path\_elements const &path, std::string &result, error\_code &ec = throws)**

Create a full name of a counter type from the contents of the given *counter\_type\_path\_elements* instance. The generated counter type name will contain all parameters.

*counter\_status* **get\_counter\_name(counter\_path\_elements const &path, std::string &result, error\_code &ec = throws)**

Create a full name of a counter from the contents of the given *counter\_path\_elements* instance.

*counter\_status* **get\_counter\_instance\_name(counter\_path\_elements const &path, std::string &result, error\_code &ec = throws)**

Create a name of a counter instance from the contents of the given *counter\_path\_elements* instance.

*counter\_status* **get\_counter\_type\_path\_elements(std::string const &name, counter\_type\_path\_elements &path, error\_code &ec = throws)**

Fill the given *counter\_type\_path\_elements* instance from the given full name of a counter type.

*counter\_status* **get\_counter\_path\_elements(std::string const &name, counter\_path\_elements &path, error\_code &ec = throws)**

Fill the given *counter\_path\_elements* instance from the given full name of a counter.

*counter\_status* **get\_counter\_name(std::string const &name, std::string &countername, error\_code &ec = throws)**

Return the canonical counter instance name from a given full instance name.

*counter\_status* **get\_counter\_type\_name(std::string const &name, std::string &type\_name, error\_code &ec = throws)**

Return the canonical counter type name from a given (full) instance name.

```

bool expand\_counter\_info(counter\_info const&, discover\_counter\_func const&, error\_code&)  
call the supplied function will all expanded versions of the supplied counter info.

This function expands all locality#\* and worker-thread#\* wild cards only.

```
counter_status remove_counter_type(counter_info const &info, error_code &ec = throws)
```

Remove an existing counter type from the (local) registry.

---

**Note:** This doesn't remove existing counters of this type, it just inhibits defining new counters using this type.

---

---

```
counter_status get_counter_type(std::string const &name, counter_info &info, error_code &ec = throws)
```

Retrieve the counter type for the given counter name from the (local) registry.

```
hpx::future<hpx::id_type> get_counter_async(std::string name, error_code &ec = throws)
```

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter name.

```
hpx::future<hpx::id_type> get_counter_async(counter_info const &info, error_code &ec = throws)
```

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter info.

```
void get_counter_infos(counter_info const &info, counter_type &type, std::string &helptext, std::uint32_t &version, error_code &ec = throws)
```

Retrieve the meta data specific for the given counter instance.

```
void get_counter_infos(std::string name, counter_type &type, std::string &helptext, std::uint32_t &version, error_code &ec = throws)
```

Retrieve the meta data specific for the given counter instance.

struct counter_value
```

## Public Functions

```
inline counter_value(std::int64_t value = 0, std::int64_t scaling = 1, bool scale_inverse = false)

template<typename T>
inline T get_value(error_code &ec = throws) const
```

Retrieve the ‘real’ value of the `counter_value`, converted to the requested type *T*.

## Public Members

`std::uint64_t time_`

The local time when data was collected.

`std::uint64_t count_`

The invocation counter for the data.

`std::int64_t value_`

The current counter value.

`std::int64_t scaling_`

The scaling of the current counter value.

`counter_status status_`

The status of the counter value.

`bool scale_inverse_`

If true, `value_` needs to be divided by `scaling_`, otherwise it has to be multiplied.

## Private Functions

```
void serialize(serialization::output_archive &ar, const unsigned int)
void serialize(serialization::input_archive &ar, const unsigned int)
```

## Friends

```
friend class hpx::serialization::access
```

```

## Public Functions

```
inline counter_values_array(std::int64_t scaling = 1, bool scale_inverse = false)
inline counter_values_array(std::vector<std::int64_t> &&values, std::int64_t scaling = 1, bool
                           scale_inverse = false)
inline counter_values_array(std::vector<std::int64_t> const &values, std::int64_t scaling = 1,
                           bool scale_inverse = false)

template<typename T>
inline T get_value(std::size_t index, error_code &ec = throws) const
    Retrieve the ‘real’ value of the counter_value, converted to the requested type T.
```

## Public Members

*std*::uint64\_t **time\_**

The local time when data was collected.

*std*::uint64\_t **count\_**

The invocation counter for the data.

*std*::vector<*std*::int64\_t> **values\_**

The current counter values.

*std*::int64\_t **scaling\_**

The scaling of the current counter values.

*counter\_status* **status\_**

The status of the counter value.

bool **scale\_inverse\_**

If true, value\_ needs to be divided by scaling\_, otherwise it has to be multiplied.

## Private Functions

## [hpx/performance\\_counters/manage\\_counter\\_type.hpp](#)

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

```
namespace performance_counters
```

## Functions

```
counter_status install_counter_type(std::string const &name, hpx::function<std::int64_t(bool)>
const &counter_value, std::string const &helptext = "",
std::string const &uom = "", counter_type type =
counter_type::raw, error_code &ec = throws)
```

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new generic counter type based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this counter type will cause the provided function to be called and the returned value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: '/objectname{locality#<\*>/total}/countername' where '<\*>' is a zero based integer identifying the locality the counter is created on.

---

**Note:** As long as *ec* is not pre-initialized to *hpx*::*throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx*::*exception*.

---

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **counter\_value** – [in] The function to call whenever the counter value is requested by a consumer.

- **helptext** – [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom** – [in] The unit of measure for the new performance counter type.
- **type** – [in] Type for the new performance counter type.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** If successful, this function returns `valid_data`, otherwise it will either throw an exception or return an `error_code` from the enum `counter_status` (also, see note related to parameter `ec`).

```
counter_status install_counter_type(std::string const &name,
                                    hpx::function<std::vector<std::int64_t>(bool)> const
                                    &counter_value, std::string const &helptext = "", std::string
                                    const &uom = "", error_code &ec = throws)
```

Install a new generic performance counter type returning an array of values in a way, that will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new generic counter type that returns an array of values based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this counter type will cause the provided function to be called and the returned array value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: '/objectname{locality#<\*>/total}/countername' where '<\*>' is a zero based integer identifying the locality the counter is created on.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **counter\_value** – [in] The function to call whenever the counter value (array of values) is requested by a consumer.
- **helptext** – [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom** – [in] The unit of measure for the new performance counter type.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** If successful, this function returns `valid_data`, otherwise it will either throw an exception or return an `error_code` from the enum `counter_status` (also, see note related to parameter `ec`).

```
void install_counter_type(std::string const &name, counter_type type, error_code &ec = throws)
```

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new counter type based on the provided `counter_type_info`. The counter type will be automatically unregistered during system shutdown.

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **type** – [in] The type of the counters of this counter\_type.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an *error\_code* from the enum *counter\_status* (also, see note related to parameter *ec*).

```
counter_status install_counter_type(std::string const &name, counter_type type, std::string const  
    &helptext, std::string const &uom = "", std::uint32_t version =  
    HPX_PERFORMANCE_COUNTER_V1, error_code &ec =  
    throws)
```

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new counter type based on the provided *counter\_type\_info*. The counter type will be automatically unregistered during system shutdown.

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **type** – [in] The type of the counters of this counter\_type.
- **helptext** – [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom** – [in] The unit of measure for the new performance counter type.
- **version** – [in] The version of the counter type. This is currently expected to be set to *HPX\_PERFORMANCE\_COUNTER\_V1*.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an *error\_code* from the enum *counter\_status* (also, see note related to parameter *ec*).

---

```
counter_status install_counter_type(std::string const &name, counter_type type, std::string const
&helptext, create_counter_func const &create_counter,
discover_counters_func const &discover_counters,
std::uint32_t version =
HPX_PERFORMANCE_COUNTER_V1, std::string const
&uom = "", error_code &ec = throws)
```

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new generic counter type based on the provided *counter\_type\_info*. The counter type will be automatically unregistered during system shutdown.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **type** – [in] The type of the counters of this counter\_type.
- **helptext** – [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **version** – [in] The version of the counter type. This is currently expected to be set to HPX\_PERFORMANCE\_COUNTER\_V1.
- **create\_counter** – [in] The function which will be called to create a new instance of this counter type.
- **discover\_counters** – [in] The function will be called to discover counter instances which can be created.
- **uom** – [in] The unit of measure of the counter type (default: "")
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an *error\_code* from the enum *counter\_status* (also, see note related to parameter *ec*).

## hpx/performance\_counters/registry.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **performance\_counters**

        class **registry**

## Public Functions

`registry()` = default

`void clear()`

Reset registry by deleting all stored counter types.

`counter_status add_counter_type(counter_info const &info, create_counter_func const &create_counter, discover_counters_func const &discover_counters, error_code &ec = throws)`

Add a new performance counter type to the (local) registry.

`counter_status discover_counter_types(discover_counter_func discover_counter, discover_counters_mode mode, error_code &ec = throws)`

Call the supplied function for all registered counter types.

`counter_status discover_counter_type(std::string const &fullname, discover_counter_func discover_counter, discover_counters_mode mode, error_code &ec = throws)`

Call the supplied function for the given registered counter type.

`inline counter_status discover_counter_type(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec = throws)`

`counter_status get_counter_create_function(counter_info const &info, create_counter_func &create_counter, error_code &ec = throws)`  
const

Retrieve the counter creation function which is associated with a given counter type.

`counter_status get_counter_discovery_function(counter_info const &info, discover_counters_func &func, error_code &ec)` const

Retrieve the counter discovery function which is associated with a given counter type.

`counter_status remove_counter_type(counter_info const &info, error_code &ec = throws)`

Remove an existing counter type from the (local) registry.

---

**Note:** This doesn't remove existing counters of this type, it just inhibits defining new counters using this type.

---

`counter_status create_raw_counter_value(counter_info const &info, std::int64_t *countervalue, naming::gid_type &id, error_code &ec = throws)`

Create a new performance counter instance of type raw\_counter based on given counter value.

`counter_status create_raw_counter(counter_info const &info, hpx::function<std::int64_t()> const &f, naming::gid_type &id, error_code &ec = throws)`

Create a new performance counter instance of type raw\_counter based on given function returning the counter value.

`counter_status create_raw_counter(counter_info const &info, hpx::function<std::int64_t(bool)> const &f, naming::gid_type &id, error_code &ec = throws)`

Create a new performance counter instance of type raw\_counter based on given function returning the counter value.

```
counter_status create_raw_counter(counter_info const &info,  
                                hpx::function<std::vector<std::int64_t>()> const &f,  
                                naming::gid_type &id, error_code &ec = throws)
```

Create a new performance counter instance of type raw\_counter based on given function returning the counter value.

```
counter_status create_raw_counter(counter_info const &info,  
                                hpx::function<std::vector<std::int64_t>(bool)> const &f,  
                                naming::gid_type &id, error_code &ec = throws)
```

Create a new performance counter instance of type raw\_counter based on given function returning the counter value.

```
counter_status create_counter(counter_info const &info, naming::gid_type &id, error_code &ec  
                               = throws)
```

Create a new performance counter instance based on given counter info.

```
counter_status create_statistics_counter(counter_info const &info, std::string const  
                                         &base_counter_name, std::vector<std::size_t>  
                                         const &parameters, naming::gid_type &id,  
                                         error_code &ec = throws)
```

Create a new statistics performance counter instance based on given base counter name and given base time interval (milliseconds).

```
counter_status create_arithmetics_counter(counter_info const &info, std::vector<std::string>  
                                         const &base_counter_names, naming::gid_type  
                                         &id, error_code &ec = throws)
```

Create a new arithmetics performance counter instance based on given base counter names.

```
counter_status create_arithmetics_counter_extended(counter_info const &info,  
                                                 std::vector<std::string> const  
                                                 &base_counter_names,  
                                                 naming::gid_type &id, error_code  
                                                 &ec = throws)
```

Create a new extended arithmetics performance counter instance based on given base counter names.

```
counter_status add_counter(hpx::id_type const &id, counter_info const &info, error_code &ec =  
                           throws)
```

Add an existing performance counter instance to the registry.

```
counter_status remove_counter(counter_info const &info, hpx::id_type const &id, error_code  
                               &ec = throws)
```

remove the existing performance counter from the registry

```
counter_status get_counter_type(std::string const &name, counter_info &info, error_code &ec  
                               = throws)
```

Retrieve counter type information for given counter name.

## Public Static Functions

## **hpx/plugin\_factories/binary\_filter\_factory.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### Defines

**HPX\_REGISTER\_BINARY\_FILTER\_FACTORY**(BinaryFilter, pluginname)

This macro is used to create and to register a minimal component factory with Hpx.Plugin.

namespace **hpx**

namespace **plugins**

```
template<typename BinaryFilter>
struct binary_filter_factory : public binary_filter_factory_base
{
    #include <binary_filter_factory.hpp> The message_handler_factory provides a minimal implementation of a message handler's factory. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a message handler's factory instance.
    Template Parameters BinaryFilter – The message handler type this factory should be responsible for.
```

### Public Functions

inline **binary\_filter\_factory**(*util*::section const \*global, *util*::section const \*local, bool isenabled)

Construct a new factory instance.

---

**Note:** The contents of both sections has to be cloned in order to save the configuration setting for later use.

---

#### Parameters

- **global** – [in] The pointer to a *hpx::util::section* instance referencing the settings read from the [settings] section of the global configuration file (hpx.ini) This pointer may be nullptr if no such section has been found.
- **local** – [in] The pointer to a *hpx::util::section* instance referencing the settings read from the section describing this component type: [hpx.components.<name>], where <name> is the instance name of the component as given in the configuration files.

**~binary\_filter\_factory()** override = default

inline *serialization*::binary\_filter \***create**(bool compress, *serialization*::binary\_filter \*next\_filter = nullptr) override

Create a new instance of a message handler

return Returns the newly created instance of the message handler supported by this factory

## Protected Attributes

*util*::section **global\_settings\_**

*util*::section **local\_settings\_**

bool **isenabled\_**

## hpx/plugin\_factories/message\_handler\_factory.hpp

## hpx/plugin\_factories/parcelport\_factory.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

## hpx/plugin\_factories/plugin\_registry.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

## Defines

**HPX\_REGISTER\_PLUGIN\_REGISTRY(...)**

This macro is used create and to register a minimal plugin registry with `Hpx.Plugin`.

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_(...)**

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_2**(PluginType, pluginname)

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_4**(PluginType, pluginname, pluginsection, pluginsuffix)

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_5**(PluginType, pluginname, pluginstring, pluginsection, pluginsuffix)

namespace **hpx**

namespace **plugins**

```
template<typename Plugin, char const *const Name, char const *const Section, char const *const  
Suffix>
```

```
struct plugin_registry : public plugin_registry_base
```

```
#include <plugin_registry.hpp> The plugin_registry provides a minimal implementation of a plugin's  
registry. If no additional functionality is required this type can be used to implement the full set of  
minimally required functions to be exposed by a plugin's registry instance.
```

**Template Parameters** **Plugin** – The plugin type this registry should be responsible for.

## Public Functions

```
inline bool get_plugin_info(std::vector<std::string> &fillini) override
```

Return the ini-information for all contained components.

**Parameters** **fillini** – [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

**Returns** Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

## runtimetime\_components

See *Public API* for a list of names and headers that are part of the public HPX API.

### hpx/runtimetime\_components/component\_factory.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

#### Defines

**HPX\_REGISTER\_COMPONENT**(type, name, mode)

Define a component factory for a component type.

This macro is used create and to register a minimal component factory for a component type which allows it to be remotely created using the *hpx::new\_<>* function.

This macro can be invoked with one, two or three arguments

#### Parameters

- **type** – The *type* parameter is a (fully decorated) type of the component type for which a factory should be defined.
- **name** – The *name* parameter specifies the name to use to register the factory. This should uniquely (system-wide) identify the component type. The *name* parameter must conform to the C++ identifier rules (without any namespace). If this parameter is not given, the first parameter is used.
- **mode** – The *mode* parameter has to be one of the defined enumeration values of the enumeration *hpx::components::factory\_state\_enum*. The default for this parameter is *hpx::components::factory\_enabled*.

### hpx/runtimetime\_components/component\_registry.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

## Defines

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY(...)**

This macro is used to register a minimal component registry with `Hpx.Plugin`.

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_(...)**

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_2(ComponentType, componentname)**

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_3(ComponentType, componentname, state)**

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_DYNAMIC\_2(ComponentType, componentname)**

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_DYNAMIC\_3(ComponentType, componentname, state)**

namespace **hpx**

namespace **components**

template<typename **Component**, *factory\_state\_enum* **state**>

struct **component\_registry** : public *component\_registry\_base*

#include <*component\_registry.hpp*> The `component_registry` provides a minimal implementation of a component's registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a component's registry instance.

**Template Parameters Component** – The component type this registry should be responsible for.

## Public Functions

inline bool **get\_component\_info**(*std::vector<std::string>* &fillini, *std::string const &filepath*, *bool is\_static = false*) override

Return the ini-information for all contained components.

**Parameters fillini** – [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

**Returns** Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

inline void **register\_component\_type**() override

Return the unique identifier of the component type this factory is responsible for.

**Parameters**

- **locality** – [in] The id of the locality this factory is responsible for.
- **agas\_client** – [in] The AGAS client to use for component id registration (if needed).

**Returns** Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.

## hpx/runtime\_components/components\_fwd.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
components::server::runtime_support *get_runtime_support_ptr()
```

namespace **components**

```
template<typename Component>
struct component_factory
```

namespace **server**

namespace **stubs**

namespace **components**

## hpx/runtime\_components/default\_distribution\_policy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

### Variables

```
static const default_distribution_policy default_layout = {}
```

A predefined instance of the default *distribution\_policy*. It will represent the local locality and will place all items to create here.

struct **default\_distribution\_policy**

```
#include <default_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.
```

## Public Functions

```
constexpr default_distribution_policy() = default
```

Default-construct a new instance of a `default_distribution_policy`. This policy will represent one locality (the local locality).

```
inline default_distribution_policy operator()(std::vector<id_type> const &locs) const
```

Create a new `default_distribution` policy representing the given set of localities.

**Parameters** `locs` – [in] The list of localities the new instance should represent

```
inline default_distribution_policy operator()(std::vector<id_type> &&locs) const
```

Create a new `default_distribution` policy representing the given set of localities.

**Parameters** `locs` – [in] The list of localities the new instance should represent

```
inline default_distribution_policy operator()(id_type const &loc) const
```

Create a new `default_distribution` policy representing the given locality

**Parameters** `loc` – [in] The locality the new instance should represent

```
template<typename Component, typename ...Ts>
```

```
inline hpx::future<hpx::id_type> create(Ts&&... vs) const
```

Create one object on one of the localities associated by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

**Parameters** `vs` – [in] The arguments which will be forwarded to the constructor of the new object.

**Returns** A future holding the global address which represents the newly created object

```
template<typename Component, typename ...Ts>
```

```
inline hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs) const
```

Create multiple objects on the localities associated by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

### Parameters

- `count` – [in] The number of objects to create
- `vs` – [in] The arguments which will be forwarded to the constructors of the new objects.

**Returns** A future holding the list of global addresses which represent the newly created objects

```
template<typename Action, typename ...Ts>
```

```
inline async_result<Action>::type async(launch policy, Ts&&... vs) const
```

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Continuation, typename ...Ts>
```

---

```
inline bool apply(Continuation &&c, threads::thread_priority priority, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

```
template<typename Action, typename ...Ts>
```

```
inline bool apply(threads::thread_priority priority, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(Continuation &&c, threads::thread_priority priority, Callback &&cb,  
        Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(threads::thread_priority priority, Callback &&cb, Ts&&... vs) const
```

```
inline std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy

---

**Note:** This function is part of the creation policy implemented by this class

```
inline hpx::id_type get_next_target() const
```

Returns the locality which is anticipated to be used for the next async operation

```
template<typename Action>
```

```
struct async_result
```

```
#include <default_distribution_policy.hpp>
```

---

**Note:** This function is part of the invocation policy implemented by this class

## Public Types

```
using type = hpx::future<typename traits::promise_local_result<typename  
hpx::traits::extract_action<Action>::remote_result_type>::type>
```

## [\*hpx/runtime\\_components/derived\\_component\\_factory.hpp\*](#)

## Defines

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY(...)**

This macro is used to create and register a minimal component factory with `Hpx.Plugin`. This macro may be used if the registered component factory is the only factory to be exposed from a particular module. If more than one factory needs to be exposed the `HPX_REGISTER_COMPONENT_FACTORY` and `HPX_REGISTER_COMPONENT_MODULE` macros should be used instead.

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_(...)**

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_3(ComponentType, componentname, basecomponentname)**

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_4(ComponentType, componentname, basecomponentname, state)**

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_DYNAMIC(...)**

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_DYNAMIC\_(...)**

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_DYNAMIC\_3(ComponentType, componentname, basecomponentname)**

**HPX\_REGISTER\_DERIVED\_COMPONENT\_FACTORY\_DYNAMIC\_4(ComponentType, componentname, basecomponentname, state)**

## hpx/runtime\_components/new.hpp

See [Public API](#) for a list of names and headers that are part of the public `HPX` API.

namespace **hpx**

### Functions

```
template<typename Component, typename...
Ts> <unspecified> new_ (id_type const &locality, Ts &&... vs)
```

Create one or more new instances of the given `Component` type on the specified locality.

This function creates one or more new instances of the given `Component` type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

---

**Note:** This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
    hpx::new_<some_component>(hpx::find_here(), ...);
hpx::id_type id = f.get();
```

---

### Parameters

- **locality** – [in] The global address of the locality where the new instance should be created on.

- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

**Returns** The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an `hpx::future` object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

---

**template<typename Component, typename... Ts> < unspecified > local\_new (Ts &&... vs)**

Create one new instance of the given Component type on the current locality.

This function creates one new instance of the given Component type on the current locality and returns a future object for the global address which can be used to reference the new component instance.

---

**Note:** This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
    hpx::local_new<some_component>(...);
hpx::id_type id = f.get();
```

---

**Note:** The difference of this function to `hpx::new_` is that it can be used in cases where the supplied arguments are non-copyable and non-movable. All operations are guaranteed to be local only.

**Parameters** **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

**Returns** The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an `hpx::future` object instance which can be used to retrieve the global address of the newly created component. If the first argument is `hpx::launch::sync` the function will directly return an `hpx::id_type`.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

---

**template<typename Component, typename... Ts> < unspecified > new\_ (id\_type const &locality, std::size\_t count, Ts &&... vs)**

Create multiple new instances of the given Component type on the specified locality.

This function creates multiple new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

---

**Note:** This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component[]>(hpx::find_here(), 10, ...);
hpx::id_type id = f.get();
```

---

### Parameters

- **locality** – [in] The global address of the locality where the new instance should be created on.
- **count** – [in] The number of component instances to create
- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

**Returns** The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component[]*, where `traits::is_component<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which holds a `std::vector<hpx::id_type>`, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component[]*, where `traits::is_client<Component>::value` evaluates to true), the function will return an *hpx::future* object instance which holds a `std::vector<hpx::id_type>`, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

```
template<typename Component, typename DistPolicy, typename...
Ts> <unspecified> new_ (DistPolicy const &policy, Ts &&... vs)
```

Create one or more new instances of the given Component type based on the given distribution policy.

This function creates one or more new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for global address which can be used to reference the new component instance(s).

---

**Note:** This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
    hpx::new_<some_component>(hpx::default_layout, ...);
hpx::id_type id = f.get();
```

---

### Parameters

- **policy** – [in] The distribution policy used to decide where to place the newly created.

- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

**Returns** The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an `hpx::future` object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

```
template<typename Component, typename DistPolicy, typename...
Ts> <unspecified> new_ (DistPolicy const &policy, std::size_t count, Ts &&... vs)
```

Create multiple new instances of the given Component type on the localities as defined by the given distribution policy.

This function creates multiple new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for the global address which can be used to reference the new component instance.

**Note:** This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component[]>(hpx::default_layout, 10, ...);
hpx::id_type id = f.get();
```

## Parameters

- **policy** – [in] The distribution policy used to decide where to place the newly created.
- **count** – [in] The number of component instances to create
- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

**Returns** The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. `Component[]`, where `traits::is_component<Component>::value` evaluates to true), the function will return an `hpx::future` object instance which holds a `std::vector<hpx::id_type>`, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. `Component[]`, where `traits::is_client<Component>::value` evaluates to true), the function will return an `hpx::future` object instance which holds a `std::vector<hpx::id_type>`, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

## runtime\_distributed

See [Public API](#) for a list of names and headers that are part of the public HPX API.

### hpx/runtime\_distributed.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

class **runtime\_distributed** : public *runtime*

#include <runtime\_distributed.hpp> The *runtime* class encapsulates the HPX runtime system in a simple to use way. It makes sure all required parts of the HPX runtime system are properly initialized.

#### Public Functions

explicit **runtime\_distributed**(*util*::*runtime\_configuration* &*rtcfg*, int (\**pre\_main*)(*runtime\_mode*) = nullptr, void (\**post\_main*)() = nullptr)

Construct a new HPX runtime instance

**Parameters** **locality\_mode** – [in] This is the mode the given runtime instance should be executed in.

**~runtime\_distributed()**

The destructor makes sure all HPX runtime services are properly shut down before exiting.

int **start**(*hpx*::*function*<*hpx\_main\_function\_type*> const &*func*, bool *blocking* = false) override

Start the runtime system.

**Parameters**

- **func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx\_main\_function\_type*.
- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally.

**Returns** If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter *func*. Otherwise it will return zero.

int **start**(bool *blocking* = false) override

Start the runtime system.

**Parameters** **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally .

**Returns** If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter *func*. Otherwise it will return zero.

int **wait**() override

Wait for the shutdown action to be executed.

**Returns** This function will return the value as returned as the result of the invocation of the function object given by the parameter *func*.

```
void stop(bool blocking = true) override
    Initiate termination of the runtime system.
Parameters blocking – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is false then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to true to wait for all internal work to be completed.

int finalize(double shutdown_timeout) override

void stop_helper(bool blocking, std::condition_variable &cond, std::mutex &mtx)
    Stop the runtime system, wait for termination.
Parameters blocking – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is false then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to true to wait for all internal work to be completed.

int suspend() override
    Suspend the runtime system.

int resume() override
    Resume the runtime system.

bool report_error(std::size_t num_thread, std::exception_ptr const &e, bool terminate_all = true) override
    Report a non-recoverable error to the runtime system.
Parameters

- num_thread – [in] The number of the operating system thread the error has been detected in.
- e – [in] This is an instance encapsulating an exception which lead to this function call.
- terminate_all – [in] Kill all localities attached to the currently running application (default: true)

bool report_error(std::exception_ptr const &e, bool terminate_all = true) override
    Report a non-recoverable error to the runtime system.
```

---

**Note:** This function will retrieve the number of the current shepherd thread and forward to the report\_error function above.

---

**Parameters**

- **e** – [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate\_all** – [in] Kill all localities attached to the currently running application (default: true)

```
int run(hpx::function<hpx_main_function_type> const &func) override
    Run the HPX runtime system, use the given function for the main thread and block waiting for all threads to finish.
```

---

**Note:** The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

---

**Parameters** **func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx\_main\_function\_type*.

This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

**Returns** This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

`int run() override`

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

**Returns** This function will always return 0 (zero).

`bool is_networking_enabled() override`

`template<typename F>`

`inline components::server::console_error_dispatcher::sink_type set_error_sink(F &&sink)`

`performance_counters::registry &get_counter_registry()`

Allow access to the registry counter registry instance used by the HPX runtime.

`performance_counters::registry const &get_counter_registry() const`

Allow access to the registry counter registry instance used by the HPX runtime.

`void register_counter_types()`

Install all performance counters related to this runtime instance.

`void register_query_counters(std::shared_ptr<util::query_counters> const &active_counters)`

`void start_active_counters(error_code &ec = throws)`

`void stop_active_counters(error_code &ec = throws)`

`void reset_active_counters(error_code &ec = throws)`

`void reinit_active_counters(bool reset = true, error_code &ec = throws)`

`void evaluate_active_counters(bool reset = false, char const *description = nullptr, error_code &ec = throws)`

`void stop_evaluating_counters(bool terminate = false)`

`naming::resolver_client &get_agas_client()`

Allow access to the AGAS client instance used by the HPX runtime.

`hpx::threads::threadmanager &get_thread_manager() override`

Allow access to the thread manager instance used by the HPX runtime.

`applier::applier &get_applier()`

Allow access to the applier instance used by the HPX runtime.

`std::string here() const override`

Returns a string of the locality endpoints (usable in debug output)

`naming::address_type get_runtime_support_lva() const`

`naming::gid_type get_next_id(std::size_t count = 1)`

`void init_id_pool_range()`

`util::unique_id_ranges &get_id_pool()`

---

```
void initialize_agas()
```

Initialize AGAS operation.

```
void add_pre_startup_function(startup_function_type f) override
```

Add a function to be executed inside a HPX thread before hpx\_main but guaranteed to be executed before any startup function registered with *add\_startup\_function*.

---

**Note:** The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

**Parameters f** – The function ‘f’ will be called from inside a HPX thread before hpx\_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

```
void add_startup_function(startup_function_type f) override
```

Add a function to be executed inside a HPX thread before hpx\_main

**Parameters f** – The function ‘f’ will be called from inside a HPX thread before hpx\_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

```
void add_pre_shutdown_function(shutdown_function_type f) override
```

Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

---

**Note:** The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

**Parameters f** – The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

```
void add_shutdown_function(shutdown_function_type f) override
```

Add a function to be executed inside a HPX thread during hpx::finalize

**Parameters f** – The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

```
hpx::util::io_service_pool *get_thread_pool(char const *name) override
```

Access one of the internal thread pools (io\_service instances) HPX is using to perform specific tasks. The three possible values for the argument name are “main\_pool”, “io\_pool”, “parcel\_pool”, and “timer\_pool”. For any other argument value the function will return zero.

```
bool register_thread(char const *name, std::size_t num = 0, bool service_thread = true, error_code &ec = throws) override
```

Register an external OS-thread with HPX.

```
notification_policy_type get_notification_policy(char const *prefix,  
                                              runtime_local::os_thread_type type) override
```

Generate a new notification policy instance for the given thread name prefix

```
std::uint32_t get_locality_id(error_code &ec) const override
```

```
std::size_t get_num_worker_threads() const override
```

```
std::uint32_t get_num_localities(hpx::launch::sync_policy, error_code &ec) const override  
std::uint32_t get_initial_num_localities() const override  
hpx::future<std::uint32_t> get_num_localities() const override  
std::string get_locality_name() const override  
std::uint32_t get_num_localities(hpx::launch::sync_policy, components::component_type type,  
                                error_code &ec) const  
hpx::future<std::uint32_t> get_num_localities(components::component_type type) const  
std::uint32_t assign_cores(std::string const &locality_basename, std::uint32_t num_threads) override  
std::uint32_t assign_cores() override
```

## hpx/runtime\_distributed/applier.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **applier**

class **applier**

#include <*applier.hpp*> The *applier* class is used to decide whether a particular action has to be issued on a local or a remote resource. If the target component is local a new *thread* will be created, if the target is remote a parcel will be sent.

### Public Functions

**HPX\_NON\_COPYABLE**(*applier*)

**applier()**

void **init**(*threads*::*threadmanager* &tm)

**~applier()** = default

void **initialize**(*std*::uint64\_t rts)

*threads*::*threadmanager* &**get\_thread\_manager**()

Access the *thread-manager* instance associated with this *applier*.

This function returns a reference to the thread manager this *applier* instance has been created with.

```
naming::gid_type const &get_raw_locality(error_code &ec = throws) const
```

Allow access to the locality of the locality this applier instance is associated with.

This function returns a reference to the locality this applier instance is associated with.

```
std::uint32_t get_locality_id(error_code &ec = throws) const
```

Allow access to the id of the locality this applier instance is associated with.

This function returns a reference to the id of the locality this applier instance is associated with.

```
bool get_raw_remote_localities(std::vector<naming::gid_type> &locality_ids,  
                               components::component_type type =  
                               components::component_invalid, error_code &ec = throws)  
const
```

Return list of localities of all remote localities registered with the AGAS service for a specific component type.

This function returns a list of all remote localities (all localities known to AGAS except the local one) supporting the given component type.

**Parameters**

- **locality\_ids** – [out] The reference to a vector of id\_types filled by the function.
- **type** – [in] The type of the component which needs to exist on the returned localities.

**Returns** The function returns *true* if there is at least one remote locality known to the AGASservice (!prefixes.empty()).

```
bool get_remote_localities(std::vector<hpx::id_type> &locality_ids,  
                           components::component_type type =  
                           components::component_invalid, error_code &ec = throws) const
```

```
bool get_raw_localities(std::vector<naming::gid_type> &locality_ids,  
                       components::component_type type =  
                       components::component_invalid) const
```

Return list of locality\_ids of all localities registered with the AGAS service for a specific component type.

This function returns a list of all localities (all localities known to AGAS except the local one) supporting the given component type.

**Parameters**

- **locality\_ids** – [out] The reference to a vector of id\_types filled by the function.
- **type** – [in] The type of the component which needs to exist on the returned localities.

**Returns** The function returns *true* if there is at least one remote locality known to the AGASservice (!prefixes.empty()).

```
bool get_localities(std::vector<hpx::id_type> &locality_ids, error_code &ec = throws) const
```

```
bool get_localities(std::vector<hpx::id_type> &locality_ids, components::component_type  
type, error_code &ec = throws) const
```

```
inline naming::gid_type const &get_runtime_support_raw_gid() const
```

By convention the runtime\_support has a gid identical to the prefix of the locality the runtime\_support is responsible for

```
inline hpx::id_type const &get_runtime_support_gid() const
```

By convention the runtime\_support has a gid identical to the prefix of the locality the runtime\_support is responsible for

## Private Members

`threads::threadmanager *thread_manager_`

`hpx::id_type runtime_support_id_`

### **hpx/runtime\_distributed/applier\_fwd.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **applier**

#### Functions

`applier &get_applier()`

The function `get_applier` returns a reference to the (thread specific) applier instance.

`applier *get_applier_ptr()`

The function `get_applier` returns a pointer to the (thread specific) applier instance. The returned pointer is NULL if the current thread is not known to HPX or if the runtime system is not active.

namespace **applier**

The namespace `applier` contains all definitions needed for the class `hpx::applier::applier` and its related functionality. This namespace is part of the HPX core module.

### **hpx/runtime\_distributed/copy\_component.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

#### Functions

```
template<typename Component>
future<hpx::id_type> copy(hpx::id_type const &to_copy)
```

Copy given component to the specified target locality.

The function `copy<Component>` will create a copy of the component referenced by `to_copy` on the locality specified with `target_locality`. It returns a future referring to the newly created component instance.

---

**Note:** The new component instance is created on the locality of the component instance which is to be copied.

---

**Parameters** **to\_copy** – [in] The global id of the component to copy  
**Template Parameters** **The** – only template argument specifies the component type to create.  
**Returns** A future representing the global id of the newly (copied) component instance.

```
template<typename Component>
future<hpx::id_type> copy(hpx::id_type const &to_copy, hpx::id_type const &target_locality)
```

Copy given component to the specified target locality.

The function *copy*<*Component*> will create a copy of the component referenced by *to\_copy* on the locality specified with *target\_locality*. It returns a future referring to the newly created component instance.

**Parameters**

- **to\_copy** – [in] The global id of the component to copy
- **target\_locality** – [in ] The locality where the copy should be created.

**Template Parameters** **The** – only template argument specifies the component type to create.  
**Returns** A future representing the global id of the newly (copied) component instance.

```
template<typename Derived, typename Stub>
Derived copy(client_base<Derived, Stub> const &to_copy, hpx::id_type const &target_locality =
            hpx::invalid_id)
```

Copy given component to the specified target locality.

The function *copy* will create a copy of the component referenced by the client side object *to\_copy* on the locality specified with *target\_locality*. It returns a new client side object future referring to the newly created component instance.

---

**Note:** If the second argument is omitted (or is invalid\_id) the new component instance is created on the locality of the component instance which is to be copied.

---

**Parameters**

- **to\_copy** – [in] The client side object representing the component to copy
- **target\_locality** – [in, optional] The locality where the copy should be created (default is same locality as source).

**Template Parameters** **The** – only template argument specifies the component type to create.  
**Returns** A future representing the global id of the newly (copied) component instance.

## hpx/runtime\_distributed/find\_all\_localities.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

`hpx::id_type find_root_locality(error_code &ec = throws)`

Return the global id representing the root locality.

The function `find_root_locality()` can be used to retrieve the global id usable to refer to the root locality. The root locality is the locality where the main AGAS service is hosted.

### See also:

`hpx::find_all_localities()`, `hpx::find_locality()`

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return `hpx::invalid_id` otherwise.

---

**Parameters** `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The global id representing the root locality for this application.

`std::vector<hpx::id_type> find_all_localities(error_code &ec = throws)`

Return the list of global ids representing all localities available to this application.

The function `find_all_localities()` can be used to retrieve the global ids of all localities currently available to this application.

### See also:

`hpx::find_here()`, `hpx::find_locality()`

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** The global ids representing the localities currently available to this application.

*std*::vector<*hpx*::id\_type> **find\_remote\_localities**(*error\_code* &*ec* = *throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function **find\_remote\_localities()** can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one).

**See also:**

*hpx::find\_here()*, *hpx::find\_locality()*

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** The global ids representing the remote localities currently available to this application.

## **hpx/runtime\_distributed/find\_here.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### **Functions**

*hpx*::id\_type **find\_here**(*error\_code* &*ec* = *throws*)

Return the global id representing this locality.

The function **find\_here()** can be used to retrieve the global id usable to refer to the current locality.

**See also:**

*hpx::find\_all\_localities()*, *hpx::find\_locality()*

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid\_id* otherwise.

---

**Parameters** **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns** The global id representing the locality this function has been called on.

## hpx/runtime\_distributed/find\_localities.hpp

See *Public API* for a list of names and headers that are part of the public *HPX API*.

namespace **hpx**

### Functions

`std::vector<hpx::id_type> find_all_localities(components::component_type type, error_code &ec = throws)`

Return the list of global ids representing all localities available to this application which support the given component type.

The function `find_all_localities()` can be used to retrieve the global ids of all localities currently available to this application which support the creation of instances of the given component type.

**See also:**

`hpx::find_here()`, `hpx::find_locality()`

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

---

### Parameters

- **type** – [in] The type of the components for which the function should return the available localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The global ids representing the localities currently available to this application which support the creation of instances of the given component type. If no localities supporting the given component type are currently available, this function will return an empty vector.

```
std::vector<hpx::id_type> find_remote_localities(components::component_type type, error_code &ec = throws)
```

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function `find_remote_localities()` can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one) which support the creation of instances of the given component type.

### See also:

`hpx::find_here()`, `hpx::find_locality()`

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

---

### Parameters

- **type** – [in] The type of the components for which the function should return the available remote localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The global ids representing the remote localities currently available to this application.

```
hpx::id_type find_locality(components::component_type type, error_code &ec = throws)
```

Return the global id representing an arbitrary locality which supports the given component type.

The function `find_locality()` can be used to retrieve the global id of an arbitrary locality currently available to this application which supports the creation of instances of the given component type.

**See also:**

`hpx::find_here()`, `hpx::find_all_localities()`

---

**Note:** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

---

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return `hpx::invalid_id` otherwise.

---

**Parameters**

- **type** – [in] The type of the components for which the function should return any available locality.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns** The global id representing an arbitrary locality currently available to this application which supports the creation of instances of the given component type. If no locality supporting the given component type is currently available, this function will return `hpx::invalid_id`.

**`hpx/runtime_distributed/get_locality_name.hpp`**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

*future<std::string>* **get\_locality\_name**(*hpx::id\_type const &id*)

Return the name of the referenced locality.

This function returns a future referring to the name for the locality of the given id.

**See also:**

`std::string get_locality_name()`

**Parameters** **id** – [in] The global id of the locality for which the name should be retrieved

**Returns** This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

## hpx/runtime\_distributed/get\_num\_localities.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

*hpx::future<std::uint32\_t> get\_num\_localities(components::component\_type t)*

Asynchronously return the number of localities which are currently registered for the running application.

The function *get\_num\_localities* asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

#### See also:

*hpx::find\_all\_localities, hpx::get\_num\_localities*

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

---

**Parameters** **t** – The component type for which the number of connected localities should be retrieved.

*std::uint32\_t get\_num\_localities(launch::sync\_policy, components::component\_type t, error\_code &ec = throws)*

Synchronously return the number of localities which are currently registered for the running application.

The function *get\_num\_localities* returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

#### See also:

*hpx::find\_all\_localities, hpx::get\_num\_localities*

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

---

### Parameters

- **t** – The component type for which the number of connected localities should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

## **hpx/runtime\_distributed/migrate\_component.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **components**

### Functions

```
template<typename Component, typename DistPolicy>
future<hpx::id_type> migrate(hpx::id_type const &to_migrate, DistPolicy const &policy)
```

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to\_migrate* to the locality specified with *target\_locality*. It returns a future referring to the migrated component instance.

#### Parameters

- **to\_migrate** – [in] The client side representation of the component to migrate.
- **policy** – [in] A distribution policy which will be used to determine the locality to migrate this object to.

#### Template Parameters

- **Component** – Specifies the component type of the component to migrate.
- **DistPolicy** – Specifies the distribution policy to use to determine the destination locality.

**Returns** A future representing the global id of the migrated component instance. This should be the same as *migrate\_to*.

```
template<typename Derived, typename Stub, typename DistPolicy>
Derived migrate(client_base<Derived, Stub> const &to_migrate, DistPolicy const &policy)
```

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to\_migrate* to the locality specified with *target\_locality*. It returns a future referring to the migrated component instance.

#### Parameters

- **to\_migrate** – [in] The client side representation of the component to migrate.
- **policy** – [in] A distribution policy which will be used to determine the locality to migrate this object to.

#### Template Parameters

- **Derived** – Specifies the component type of the component to migrate.
- **DistPolicy** – Specifies the distribution policy to use to determine the destination locality.

**Returns** A future representing the global id of the migrated component instance. This should be the same as *migrate\_to*.

```
template<typename Component>
future<hpx::id_type> migrate(hpx::id_type const &to_migrate, hpx::id_type const &target_locality)
```

Migrate the component with the given id to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to\_migrate* to the locality specified with *target\_locality*. It returns a future referring to the migrated component instance.

#### Parameters

- **to\_migrate** – [in] The global id of the component to migrate.
- **target\_locality** – [in] The locality where the component should be migrated to.

**Template Parameters** **Component** – Specifies the component type of the component to migrate.

**Returns** A future representing the global id of the migrated component instance. This should be the same as *migrate\_to*.

```
template<typename Derived, typename Stub>
inline Derived migrate(client_base<Derived, Stub> const &to_migrate, hpx::id_type const
&target_locality)
```

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to\_migrate* to the locality specified with *target\_locality*. It returns a future referring to the migrated component instance.

**Parameters**

- **to\_migrate** – [in] The client side representation of the component to migrate.
- **target\_locality** – [in] The id of the locality to migrate this object to.

**Template Parameters** **Derived** – Specifies the component type of the component to migrate.

**Returns** A client side representation of representing of the migrated component instance. This should be the same as *migrate\_to*.

## hpx/runtime\_distributed/runtime\_fwd.hpp

```
class runtime_support : public hpx::components::stubs::runtime_support
```

```
#include <runtime_support.hpp> The runtime_support class is the client side representation of a
server::runtime_support component
```

## Public Functions

```
inline runtime_support(hpx::id_type const &gid = hpx::invalid_id)
    Create a client side representation for the existing server::runtime_support instance with the given
    global id gid.
```

```
template<typename Component, typename ...Ts>
inline hpx::id_type create_component(Ts&&... vs)
    Create a new component type using the runtime_support.
```

```
template<typename Component, typename ...Ts>
inline hpx::future<hpx::id_type> create_component_async(Ts&&... vs)
    Asynchronously create a new component using the runtime_support.
```

```
template<typename Component, typename ...Ts>
inline std::vector<hpx::id_type> bulk_create_component(std::size_t, Ts&&... vs)
    Asynchronously create N new default constructed components using the runtime_support
```

```
template<typename Component, typename ...Ts>
inline hpx::future<std::vector<hpx::id_type>> bulk_create_components_async(std::size_t,
    Ts&&... vs)
    Asynchronously create a new component using the runtime_support.
```

```
inline hpx::future<int> load_components_async()
```

```
inline int load_components()
```

```
inline hpx::future<void> call_startup_functions_async(bool pre_startup)
```

```
inline void call_startup_functions(bool pre_startup)
```

```
inline hpx::future<void> shutdown_async(double timeout = -1)
    Shutdown the given runtime system.
```

```
inline void shutdown(double timeout = -1)
```

```
inline void shutdown_all(double timeout = -1)
    Shutdown the runtime systems of all localities.
```

```
inline hpx::future<void> terminate_async()
```

```
Terminate the given runtime system.
```

```
inline void terminate()
```

```
inline void terminate_all()
    Terminate the runtime systems of all localities.
```

```
inline void get_config(util::section &ini)
    Retrieve configuration information.
```

```
inline hpx::id_type const &get_id() const
```

```
inline naming::gid_type const &get_raw_gid() const
```

## Private Types

```
typedef stubs::runtime_support base_type
```

## Private Members

```
hpx::id_type gid
```

### **hpx/runtime\_distributed/server/copy\_component.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

future<hpx::id_type> copy_component_here(hpx::id_type const &to_copy)
```

```
template<typename Component>
future<hpx::id_type> copy_component(hpx::id_type const &to_copy, hpx::id_type const &target_locality)
```

```
template<typename Component>
struct copy_component_action : public hpx::actions::action<future<hpx::id_type>
(*)(hpx::id_type const &, hpx::id_type const &, &copy_component<Component>, copy_component_action<Component>>)
```

```
template<typename Component>
struct copy_component_action_here : public hpx::actions::action<future<hpx::id_type>
(*)(hpx::id_type const &, &copy_component_here<Component>, copy_component_action_here<Component>>)
```

### **hpx/runtime\_distributed/server/runtime\_support.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

    namespace **components**

---

namespace **server**

class **runtime\_support**

### Public Types

typedef *runtime\_support* **type\_holder**

### Public Functions

```
explicit runtime_support(hpx::util::runtime_configuration &cfg)
inline ~runtime_support()

void delete_function_lists()

void tidy()

template<typename Component>
naming::gid_type create_component()
    Actions to create new objects.

template<typename Component, typename T, typename ...Ts>
naming::gid_type create_component(T v, Ts... vs)

template<typename Component>
std::vector<naming::gid_type> bulk_create_component(std::size_t count)

template<typename Component, typename T, typename ...Ts>
std::vector<naming::gid_type> bulk_create_component(std::size_t count, T v, Ts... vs)

template<typename Component>
naming::gid_type copy_create_component(std::shared_ptr<Component> const &p, bool)

template<typename Component>
naming::gid_type migrate_component_to_here(std::shared_ptr<Component> const &p,
                                                hpx::id_type)

void shutdown(double timeout, hpx::id_type const &respond_to)
    Gracefully shutdown this runtime system instance.

void shutdown_all(double timeout)
    Gracefully shutdown runtime system instances on all localities.

void terminate(hpx::id_type const &respond_to)
    Shutdown this runtime system instance.

inline void terminate_act(hpx::id_type const &id)

void terminate_all()
    Shutdown runtime system instances on all localities.

inline void terminate_all_act()
```

```
util::section get_config()
    Retrieve configuration information.

int load_components()
    Load all components on this locality.

void call_startup_functions(bool pre_startup)

void call_shutdown_functions(bool pre_shutdown)

void garbage_collect()
    Force a garbage collection operation in the AGAS layer.

naming::gid_type create_performance_counter(performance_counters::counter_info const
    &info)

    Create the given performance counter instance.

void remove_from_connection_cache(naming::gid_type const &gid,
    parcelset::endpoints_type const &eps)

    Remove the given locality from our connection cache.

HPX_DEFINE_COMPONENT_ACTION(runtime_support, terminate_act,
terminate_action) HPX_DEFINE_COMPONENT_ACTION(runtime_support
    termination detection

terminate_all_action HPX_DEFINE_COMPONENT_ACTION(runtime_support,
remove_from_connection_cache) void run()

    Start the runtime_support component.

void wait()
    Wait for the runtime_support component to notify the calling thread.

    This function will be called from the main thread, causing it to block while the HPX functionality is executed. The main thread will block until the shutdown_action is executed, which in turn notifies all waiting threads.

void stop(double timeout, hpx::id_type const &respond_to, bool remove_from_remote_caches)
    Notify all waiting (blocking) threads allowing the system to be properly stopped.
```

---

**Note:** This function can be called from any thread.

---

```
void stopped()
    called locally only

void notify_waiting_main()

inline bool was_stopped() const

void add_pre_startup_function(startup_function_type f)

void add_startup_function(startup_function_type f)

void add_pre_shutdown_function(shutdown_function_type f)

void add_shutdown_function(shutdown_function_type f)
```

```
void remove_here_from_connection_cache()
void remove_here_from_console_connection_cache()
```

## Public Members

`terminate_all_act`

## Public Static Functions

```
static inline component_type get_component_type()
static inline void set_component_type(component_type t)
static inline constexpr void finalize()
    finalize() will be called just before the instance gets destructed
Parameters

- self – [in] The HPX thread used to execute this function.
- appl – [in] The applier to be used for finalization of the component instance.

static inline bool is_target_valid(hpx::id_type const &id)
```

## Protected Functions

```

```

Subclassed by *hpx::components::runtime\_support*

## Public Static Functions

```
template<typename Component, typename ...Ts>
```

```
static inline hpx::future<hpx::id_type> create_component_async(hpx::id_type const &gid,  
    Ts&... vs)
```

Create a new component *type* using the `runtime_support` with the given *targetgid*. This is a non-blocking call. The caller needs to call `future::get` on the result of this function to obtain the global id of the newly created object.

```
template<typename Component, typename ...Ts>
```

static inline *hpx::id\_type* **create\_component**(*hpx::id\_type* const &gid, *Ts*&&... vs)

Create a new component *type* using the *runtime\_support* with the given *targetgid*. Block for the creation to finish.

```
template<typename Component, typename ...Ts>
```

Create multiple new components *type* using the *runtime\_support* colocated with the with the given *targetgid*. This is a non-blocking call.

```
template<typename Component, typename ...Ts>
static inline std::vector<hpx::id_type> bulk_create_component_colocated(hpx::id_type
    const &gid,
    std::size_t
    count, Ts&&...
    vs)
```

Create multiple new components *type* using the *runtime\_support* colocated with the with the given *targetgid*. Block for the creation to finish.

```
template<typename Component, typename ...Ts>
static inline hpx::future<std::vector<hpx::id_type>> bulk_create_component_async(hpx::id_type
    const
    &gid,
    std::size_t
    count,
    Ts&&...
    vs)
```

Create multiple new components *type* using the *runtime\_support* on the given locality. This is a non-blocking call.

```
template<typename Component, typename ...Ts>
static inline std::vector<hpx::id_type> bulk_create_component(hpx::id_type const &gid,
    std::size_t count, Ts&&...
    vs)
```

Create multiple new components *type* using the *runtime\_support* on the given locality. Block for the creation to finish.

```
template<typename Component, typename ...Ts>
static inline hpx::future<hpx::id_type> create_component_colocated_async(hpx::id_type
    const &gid,
    Ts&&... vs)
```

Create a new component *type* using the *runtime\_support* with the given *targetgid*. This is a non-blocking call. The caller needs to call *future::get* on the result of this function to obtain the global id of the newly created object.

```
template<typename Component, typename ...Ts>
static inline hpx::id_type create_component_colocated(hpx::id_type const &gid, Ts&&...
    vs)
```

Create a new component *type* using the *runtime\_support* with the given *targetgid*. Block for the creation to finish.

```

Reduce, typename Convert>
parallel::util::detail::algorithm_result<ExPolicy, T>::type tag_invoke(hpx::transform_reduce_t,
    ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, T init, Reduce &&red_op,
    Convert &&conv_op)
```

## 2.9 Contributing to HPX

HPX development happens on Github. The following sections are a collection of useful information related to HPX development.

## 2.9.1 Contributing to HPX

The main source of information to understand the process of how to contribute to HPX can be found in [this document](#)<sup>473</sup>. This is a living document that is constantly updated with relevant information.

## 2.9.2 HPX governance model

The *HPX* project is a meritocratic, consensus-based community project. Anyone with an interest in the project can join the community, contribute to the project design and participate in the decision making process. [This document](#)<sup>474</sup> describes how that participation takes place and how to set about earning merit within the project community.

## 2.9.3 Release procedure for HPX

Below is a step by step procedure for making an *HPX* release. We aim to produce two releases per year: one in March-April, and one in September-October.

This is a living document and may not be totally current or accurate. It is an attempt to capture current practices in making an *HPX* release. Please update it as appropriate.

One way to use this procedure is to print a copy and check off the lines as they are completed to avoid confusion.

1. Notify developers that a release is imminent.
2. For minor and major releases: create and check out a new branch at an appropriate point on `master` with the name `release-major.minor.X`. `major` and `minor` should be the major and minor versions of the release. For patch releases: check out the corresponding `release-major.minor.X` branch.
3. Write release notes in `docs/sphinx/releases/whats_new_{$VERSION}.rst`. Keep adding merged PRs and closed issues to this until just before the release is made. Use `tools/generate_pr_issue_list.sh` to generate the lists. Add the new release notes to the table of contents in `docs/sphinx/releases.rst`.
4. Build the docs, and proof-read them. Update any documentation that may have changed, and correct any typos. Pay special attention to:
  - `$HPX_SOURCE/README.rst`
    - Update grant information
  - `docs/sphinx/releases/whats_new_{$VERSION}.rst`
  - `docs/sphinx/about_hpx/people.rst`
    - Update collaborators
    - Update grant information
5. This step does not apply to patch releases. For both APEX and libCDS:
  - Change the release branch to be the most current release tag available in the APEX/libCDS `git_external` section in the main `CMakeLists.txt`. Please contact the maintainers of the respective packages to generate a new release to synchronize with the *HPX* release ([APEX](#)<sup>475</sup>, [libCDS](#)<sup>476</sup>).
6. Make sure `HPX_VERSION_MAJOR/MINOR/SUBMINOR` in `CMakeLists.txt` contain the correct values. Change them if needed.
7. Change version references in `CITATION.cff`. There are two occurrences.

<sup>473</sup> <https://github.com/STELLAR-GROUP/hpx/blob/master/.github/CONTRIBUTING.md>

<sup>474</sup> <http://hpx.stellar-group.org/documents/governance/>

<sup>475</sup> <http://github.com/UO-OACISS/xpress-apex>

<sup>476</sup> <https://github.com/STELLAR-GROUP/libcds>

8. This step does not apply to patch releases. Remove features which have been deprecated for at least 2 releases. This involves removing build options which enable those features from the main CMakeLists.txt and also deleting all related code and tests from the main source tree.

The general deprecation policy involves a three-step process we have to go through in order to introduce a breaking change:

- a. First release cycle: add a build option that allows for explicitly disabling any old (now deprecated) code.
- b. Second release cycle: turn this build option OFF by default.
- c. Third release cycle: completely remove the old code.

The main CMakeLists.txt contains a comment indicating for which version the breaking change was introduced first. In the case of deprecated features which don't have a replacement yet, we keep them around in case (like Vc for example).

9. Update the minimum required versions if necessary (compilers, dependencies, etc.) in `building_hpx.rst`.
10. Verify that the Jenkins setups for the release branch on Rostam and Piz Daint are running and do not display any errors.
11. Repeat the following steps until satisfied with the release.
  1. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to `-rcN`, where N is the current iteration of this step. Start with `-rc1`.
  2. Create a pre-release on GitHub using the script `tools/roll_release.sh`. This script automatically tag with the corresponding release number. The script requires that you have the STE||AR Group signing key.
  3. This step is not necessary for patch releases. Notify `hpx-users@stellar-group.org` and `stellar@cct.lsu.edu` of the availability of the release candidate. Ask users to test the candidate by checking out the release candidate tag.
  4. Allow at least a week for testing of the release candidate.
    - Use `git merge` when possible, and fall back to `git cherry-pick` when needed. For patch releases `git cherry-pick` is most likely your only choice if there have been significant unrelated changes on master since the previous release.
    - Go back to the first step when enough patches have been added.
    - If there are no more patches, continue to make the final release.
12. Update any occurrences of the latest stable release to refer to the version about to be released. For example, `quickstart.rst` contains instructions to check out the latest stable tag. Make sure that refers to the new version.
13. Add a new entry to the RPM changelog (`cmake/packaging/rpm/Changelog.txt`) with the new version number and a link to the corresponding changelog.
14. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to an empty string.
15. Add the release date to the caption of the current “What’s New” section in the docs, and change the value of `HPX_VERSION_DATE` in `CMakeLists.txt`.
16. Create a release on GitHub using the script `tools/roll_release.sh`. This script automatically tag the with the corresponding release number. The script requires that you have the STE||AR Group signing key.
17. Update the websites ([hpx.stellar-group.org<sup>477</sup>](https://hpx.stellar-group.org), [stellar-group.org<sup>478</sup>](https://stellar-group.org) and [stellar.cct.lsu.edu<sup>479</sup>](https://stellar.cct.lsu.edu)). You can login on wordpress through *this page* <<https://hpx.stellar-group.org/wp-login.php>>. You can update the pages with the following:

---

<sup>477</sup> <https://hpx.stellar-group.org>

<sup>478</sup> <https://stellar-group.org>

<sup>479</sup> <https://stellar.cct.lsu.edu>

- Update links on the downloads page. Link to the release on GitHub.
  - Documentation links on the docs page (link to generated documentation on GitHub Pages). Follow the style of previous releases.
  - A new blog post announcing the release, which links to downloads and the “What’s New” section in the documentation (see previous releases for examples).
18. Merge release branch into master.
  19. Post-release cleanup. Create a new pull request against master with the following changes:
    1. Modify the release procedure if necessary.
    2. Change HPX\_VERSION\_TAG in CMakeLists.txt back to -trunk.
    3. Increment HPX\_VERSION\_MINOR in CMakeLists.txt.
  20. Update Vcpkg (<https://github.com/Microsoft/vcpkg>) to pull from latest release.
    - Update version number in CONTROL
    - Update tag and SHA512 to that of the new release
  21. Update spack (<https://github.com/spack/spack>) with the latest HPX package.
    - Update version number in hpx/package.py and SHA256 to that of the new release
  22. Announce the release on [hpx-users@stellar-group.org](mailto:hpx-users@stellar-group.org), [stellar@cct.lsu.edu](mailto:stellar@cct.lsu.edu), [allcct@cct.lsu.edu](mailto:allcct@cct.lsu.edu), [faculty@csc.lsu.edu](mailto:faculty@csc.lsu.edu), [faculty@ece.lsu.edu](mailto:faculty@ece.lsu.edu), [xpress@crest.iu.edu](mailto:xpress@crest.iu.edu), the HPX Slack channel, the IRC channel, our list of external collaborators, [isocpp.org](http://isocpp.org), [reddit.com](http://reddit.com), HPC Wire, Inside HPC, Heise Online, and a CCT press release.
  23. Beer and pizza.

## 2.9.4 Testing HPX

To ensure correctness of *HPX*, we ship a large variety of unit and regression tests. The tests are driven by the CTest<sup>480</sup> tool and are executed automatically on each commit to the *HPX* Github<sup>481</sup> repository. In addition, it is encouraged to run the test suite manually to ensure proper operation on your target system. If a test fails for your platform, we highly recommend submitting an issue on our *HPX* Issues<sup>482</sup> tracker with detailed information about the target system.

### Running tests manually

Running the tests manually is as easy as typing `make tests && make test`. This will build all tests and run them once the tests are built successfully. After the tests have been built, you can invoke separate tests with the help of the `ctest` command. You can list all available test targets using `make help | grep tests`. Please see the CTest Documentation<sup>483</sup> for further details.

<sup>480</sup> <https://gitlab.kitware.com/cmake/community/wikis/doc/ctest/Testing-With-CTest>

<sup>481</sup> <https://github.com/STELLAR-GROUP/hpx/>

<sup>482</sup> <https://github.com/STELLAR-GROUP/hpx/issues>

<sup>483</sup> <https://www.cmake.org/cmake/help/latest/manual/ctest.1.html>

## Running performance tests

We run performance tests on Piz Daint for each pull request using Jenkins. To run those performance tests locally or on Piz Daint, a script is provided under `tools/perftests_ci/local_run.sh` (to be run in the build directory specifying the *HPX* source directory as the argument to the script, default is `$HOME/projects/hpx_perftests_ci`).

## Adding new performance tests

To add a new performance test, you need to wrap the portion of code to benchmark with `hpx::util::perftests_report`, passing the test name, the executor name and the function to time (can be a lambda). This facility is used to output the time results in a json format (format needed to compare the results and plot them). To effectively print them at the end of your test, call `hpx::util::perftests_print_times`. To see an example of use, see `future_overhead_report.cpp`. Finally, you can add the test to the CI report editing the `hpx_targets` variable for the executable name and the `hpx_test_options` variable for the corresponding options to use for the run in the performance test script `.jenkins/cscs-perftests/launch_perftests.sh`. And then run the `tools/perftests_ci/local_run.sh` script to get a reference json run (use the name of the test) to be added in the `tools/perftests_ci/perftest/references/daint_default` directory.

## Issue tracker

If you stumble over a bug or missing feature in *HPX*, please submit an issue to our [HPX Issues<sup>484</sup>](#) page. For more information on how to submit support requests or other means of getting in contact with the developers, please see the [Support Website<sup>485</sup>](#) page.

## Continuous testing

In addition to manual testing, we run automated tests on various platforms. We also run tests on all pull requests using both [CircleCI<sup>486</sup>](#) and a combination of [CDash<sup>487</sup>](#) and [pycicle<sup>488</sup>](#). You can see the dashboards here: [CircleCI HPX dashboard<sup>489</sup>](#) and [CDash HPX dashboard<sup>490</sup>](#).

## 2.9.5 Using docker for development

Although it can often be useful to set up a local development environment with system-provided or self-built dependencies, [Docker<sup>491</sup>](#) provides a convenient alternative to quickly get all the dependencies needed to start development of *HPX*. Our testing setup on [CircleCI<sup>492</sup>](#) uses a docker image to run all tests.

To get started you need to install [Docker<sup>493</sup>](#) using whatever means is most convenient on your system. Once you have [Docker<sup>494</sup>](#) installed, you can pull or directly run the docker image. The image is based on Debian and Clang, and can be found on [Docker Hub<sup>495</sup>](#). To start a container using the *HPX* build environment, run:

<sup>484</sup> <https://github.com/STELLAR-GROUP/hpx/issues>

<sup>485</sup> <https://stellar.cct.lsu.edu/support/>

<sup>486</sup> <https://circleci.com>

<sup>487</sup> <https://www.kitware.com/cdash/project/about.html>

<sup>488</sup> <https://github.com/biddisco/pycicle/>

<sup>489</sup> <https://circleci.com/gh/STELLAR-GROUP/hpx>

<sup>490</sup> <https://cdash.cscs.ch/index.php?project=HPX>

<sup>491</sup> <https://www.docker.com>

<sup>492</sup> <https://circleci.com>

<sup>493</sup> <https://www.docker.com>

<sup>494</sup> <https://www.docker.com>

<sup>495</sup> [https://hub.docker.com/r/stellargroup/build\\_env/](https://hub.docker.com/r/stellargroup/build_env/)

```
$ docker run --interactive --tty stellargroup/build_env:latest bash
```

You are now in an environment where all the *HPX* build and runtime dependencies are present. You can install additional packages according to your own needs. Please see the [Docker Documentation<sup>496</sup>](#) for more information on using Docker<sup>497</sup>.

**Warning:** All changes made within the container are lost when the container is closed. If you want files to persist (e.g., the *HPX* source tree) after closing the container, you can bind directories from the host system into the container (see [Docker Documentation \(Bind mounts\)<sup>498</sup>](#)).

## 2.9.6 Documentation

This documentation is built using [Sphinx<sup>499</sup>](#), and an automatically generated API reference using [Doxygen<sup>500</sup>](#) and [Breathe<sup>501</sup>](#).

We always welcome suggestions on how to improve our documentation, as well as pull requests with corrections and additions.

### Prerequisites

To build the *HPX* documentation, you need recent versions of the following packages:

- `python3`
- `sphinx 4.5.0` (Python package)
- `sphinx-book-theme` (Python package)
- `breathe 4.33.1` (Python package)
- `doxygen`
- `sphinxcontrib-bibtex`

If the [Python<sup>502</sup>](#) dependencies are not available through your system package manager, you can install them using the Python package manager pip:

```
pip install --user "sphinx<5" sphinx-book-theme breathe sphinxcontrib-bibtex
```

You may need to set the following CMake variables to make sure CMake can find the required dependencies.

#### DOXYGEN\_ROOT:PATH

Specifies where to look for the installation of the [Doxygen<sup>503</sup>](#) tool.

#### SPHINX\_ROOT:PATH

Specifies where to look for the installation of the [Sphinx<sup>504</sup>](#) tool.

<sup>496</sup> <https://docs.docker.com/>

<sup>497</sup> <https://www.docker.com>

<sup>498</sup> <https://docs.docker.com/storage/bind-mounts/>

<sup>499</sup> <http://www.sphinx-doc.org>

<sup>500</sup> <https://www.doxygen.org>

<sup>501</sup> <https://breathe.readthedocs.io/en/latest>

<sup>502</sup> <https://www.python.org>

<sup>503</sup> <https://www.doxygen.org>

<sup>504</sup> <http://www.sphinx-doc.org>

## BREATHE\_APIDOC\_ROOT:PATH

Specifies where to look for the installation of the Breathe<sup>505</sup> tool.

## Building documentation

Enable building of the documentation by setting HPX\_WITH\_DOCUMENTATION=ON during CMake<sup>506</sup> configuration. To build the documentation, build the docs target using your build tool. The default output format is HTML documentation. You can choose alternative output formats (single-page HTML, PDF, and man) with the HPX\_WITH\_DOCUMENTATION\_OUTPUT\_FORMATS CMake option.

---

**Note:** If you add new source files to the Sphinx documentation, you have to run CMake again to have the files included in the build.

---

## Style guide

The documentation is written using reStructuredText. These are the conventions used for formatting the documentation:

- Use, at most, 80 characters per line.
- Top-level headings use over- and underlines with =.
- Sub-headings use only underlines with characters in decreasing level of importance: =, - and ..
- Use sentence case in headings.
- Refer to common terminology using :term:`Component`.
- Indent content of directives (.. directive::) by three spaces.
- For C++ code samples at the end of paragraphs, use :: and indent the code sample by 4 spaces.
  - For other languages (or if you don't want a colon at the end of the paragraph), use .. code-block:: language and indent by three spaces as with other directives.
- Use .. list-table:: to wrap tables with a lot of text in cells.

## API documentation

The source code is documented using Doxygen. If you add new API documentation either to existing or new source files, make sure that you add the documented source files to the doxygen\_dependencies variable in docs/CMakeLists.txt.

## 2.9.7 Module structure

This section explains the structure of an *HPX* module.

The tool `create_library_skeleton.py`<sup>507</sup> can be used to generate a basic skeleton. To create a library skeleton, run the tool in the `libs` subdirectory with the module name as an argument:

```
$ ./create_library_skeleton <lib_name>
```

---

<sup>505</sup> <https://breathe.readthedocs.io/en/latest>

<sup>506</sup> <https://www.cmake.org>

<sup>507</sup> [https://github.com/STELLAR-GROUP/hpx/blob/master/libs/create\\_library\\_skeleton.py](https://github.com/STELLAR-GROUP/hpx/blob/master/libs/create_library_skeleton.py)

This creates a skeleton with the necessary files for an *HPX* module. It will not create any actual source files. The structure of this skeleton is as follows:

```
• <lib_name>/
  - README.rst
  - CMakeLists.txt
  - cmake
  - docs/
    * index.rst
  - examples/
    * CMakeLists.txt
  - include/
    * hpx/
      · <lib_name>
  - src/
    * CMakeLists.txt
  - tests/
    * CMakeLists.txt
    * unit/
      · CMakeLists.txt
  - regressions/
    · CMakeLists.txt
  - performance/
    · CMakeLists.txt
```

A `README.rst` should be always included which explains the basic purpose of the library and a link to the generated documentation.

A main `CMakeLists.txt` is created in the root directory of the module. By default it contains a call to `add_hpx_module` which takes care of most of the boilerplate required for a module. You only need to fill in the source and header files in most cases.

`add_hpx_module` requires a module name. Optional flags are:

Optional single-value arguments are:

- `INSTALL_BINARIES`: Install the resulting library.

Optional multi-value arguments-are:

- `SOURCES`: List of source files.
- `HEADERS`: List of header files.
- `COMPAT_HEADERS`: List of compatibility header files.
- `DEPENDENCIES`: Libraries that this module depends on, such as other modules.
- `CMAKE_SUBDIRS`: List of subdirectories to add to the module.

The `include` directory should contain only headers that other libraries need. For each of those headers, an automatic header test to check for self containment will be generated. Private headers should be placed under the `src` directory. This allows for clear separation. The `cmake` subdirectory may include additional CMake<sup>508</sup> scripts needed to generate the respective build configurations.

Compatibility headers (forwarding headers for headers whose location is changed when creating a module, if moving them from the main library) should be placed in an `include_compatibility` directory. This directory is not created by default.

Documentation is placed in the `docs` folder. A empty skeleton for the index is created, which is picked up by the main build system and will be part of the generated documentation. Each header inside the `include` directory will automatically be processed by Doxygen and included into the documentation.

Tests are placed in suitable subdirectories of `tests`.

When in doubt, consult existing modules for examples on how to structure the module.

## Finding circular dependencies

Our CI will perform a check to see if there are circular dependencies between modules. In cases where it's not clear what is causing the circular dependency, running the `cpp-dependencies`<sup>509</sup> tool manually can be helpful. It can give you detailed information on exactly which files are causing the circular dependency. If you do not have the `cpp-dependencies` tool already installed, one way of obtaining it is by using our docker image. This way you will have exactly the same environment as on the CI. See [Using docker for development](#) for details on how to use the docker image.

To produce the graph produced by CI run the following command (`HPX_SOURCE` is assumed to hold the path to the `HPX` source directory):

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --graph-cycles circular_dependencies.dot
```

This will produce a `.dot` file in the current directory. You can inspect this manually with a text editor. You can also convert this to an image if you have `graphviz` installed:

```
$ dot circular_dependencies.dot -Tsvg -o circular_dependencies.svg
```

This produces an `.svg` file in the current directory which shows the circular dependencies. Note that if there are no cycles the image will be empty.

You can use `cpp-dependencies` to print the include paths between two modules.

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --shortest <from> <to>
```

prints all possible paths from the module `<from>` to the module `<to>`. For example, as most modules depend on `config`, the following should give you a long list of paths from `algorithms` to `config`:

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --shortest algorithms config
```

The following should report that it can't find a path between the two modules:

```
$ cpp-dependencies --dir $HPX_SOURCE/libs --shortest config algorithms
```

## 2.10 Releases

### 2.10.1 HPX V1.8.0 (May 18, 2022)

With HPX parallel algorithms been fully adapted to C++20 the new release achieves full conformance with C++20 concurrency and parallelism facilities. HPX now supports all of the algorithms as specified by C++20. We have added support for vectorization to more of our algorithms. Much work has been done towards implementing P2300 (“`std::execution`”) and implementing the underlying senders/receivers facilities. Finally, The new release comes with a brand new documentation interface!

#### General changes

- The new documentation can now be found on our webpage: <https://hpx-docs.stellar-group.org>. This includes a completely new and user-friendly interface environment along with restructuring of certain components. The content in the “Quick start”, “Manual” and “Examples” was improved, while the “Build system” page was adapted to include necessary information for newcomers.
- With the vectorization support available in modern hardware architectures HPX now provides new data-parallel vector execution policies `hpx::execution::simd` and `hpx::execution::par_simd` that enable significant speed-up of our parallel algorithm implementations. The following algorithms now support SIMD execution:
  - `copy`, `copy_n`
  - `generate`
  - `adjacent_difference`, `adjacent_find`
  - `all_of`, `any_of`, `none_of`
  - `equal`, `mismatch`,
  - `inner_product`
  - `count`, `count_if`
  - `fill`, `fill_n`
  - `find`, `find_end`, `find_first_of`, `find_if`, `find_if_not`
  - `for_each`, `for_each_n`
  - `generate`, `generate_n`.
- Based on top of P2300 the HPX parallel algorithms now support the pipeline syntax towards an effort to unify their usage along with senders/receivers. The HPX parallel algorithms can now bind with senders/receivers using the pipeline operator.
- Several changes took place on the executors provided by HPX:
- The executors now support the `num_cores` options in order for the user to be able to specify the desired number of cores to be used in the correspodning execution.
- The `scheduler` executor was implemented on top of senders/receivers and can be used with all HPX facilities that schedule new work, such as parallel algorithms, `hpx::async`, `hpx::dataflow`, etc.
- The performance of `fork_join_executor` was improved.
- The following algorithms have been added/adapted to be C++20 conformant:
  - `min_element`
  - `max_element`

- `minmax_element`
- `starts_with`
- `ends_with`
- `swap_ranges`
- `unique`
- `unique_copy`
- `rotate`
- `rotate_copy`
- `sort`
- `shift_left`
- `shift_right`
- `stable_sort`
- `partition`
- `partition_copy`
- `stable_partition`
- `adjacent_difference`
- `nth_element`
- `partial_sort`
- `partial_sort_copy`.

- HPX\_FORWARD/HPX\_MOVE macros were introduced that replaced the `std::move` and `std::forward` facilities that in the library code.
- Hangs on distributed barrier were fixed.
- The performance of `scan_partitioner` was improved.
- Support was added for `thread_priority` to the `parallel_execution_policy`
- Regarding senders/receivers and the P2300 proposal various actions took place. `stop_token` was adapted to the recent proposal version (`in_place_stop_token` was introduced). Also hint, annotation, priority and stacksize properties were added to the scheduler executor. Stop support was added to `when_all`. Support for completion signatures was added. The following schedulers and algorithms were added:

- `get_completion_scheduler`
- `any_sender` and `unique_any_sender`
- `split sender`
- `transform_mpi sender`
- `transfer sender`
- `let_error, let_stopped`
- `get_env` and related environment queries
- `schedule, set_value, set_error, set_done, start` and `connect` are now proper customization points as defined in P2300.

- Several namespaces were altered towards conformance with C++20. Compatibility layers have been added and the old versions will be removed in next releases. The namespace changes are the following:
  - `hpx::parallel::induction/reduction` were moved into namespace `hpx::experimental`
  - `for_loop` and friends were moved into namespace `hpx::experimental`.
  - `hpx::util::optional` and friends were moved into namespace `hpx`.
  - `hpx::lcos::barrier` has been moved into the `hpx::distributed` namespace and `hpx::lcos::local::cpp20_barrier` has been renamed to `barrier` and moved into the `hpx` namespace.
  - `hpx::lcos::latch` has been moved into the `hpx::distributed` namespace and `lcos::local::latch` has been moved into the `hpx` namespace. The `count_down_and_wait()` functionality of `latch` has been renamed to `arrive_and_wait()`.
  - `hpx::util::unique_function_nons` has been renamed to `hpx::move_only_function`.
  - `hpx::util::unique_function` has been renamed to `hpx::distributed::move_only_function`.
  - `hpx::util::function` has been renamed to `hpx::distributed::function`.
  - `hpx::util::function_nons` has been renamed to `hpx::function`.
  - `hpx::util::function_ref` have been moved to namespace `hpx`.
  - `hpx::lcos::split_future` changed namespace and is now used as `hpx::split_future`.
  - `hpx::lcos::local::counting_semaphore` has been deprecated and `hpx::lcos::local::cpp20_counting_semaphore` has been renamed to `hpx::counting_semaphore`.
  - `hpx::lcos::local::cpp20_binary_semaphore` has been renamed to `hpx::binary_semaphore`.
  - `hpx::lcos::local::sliding_semaphore` has been renamed to `hpx::sliding_semaphore` and
  - `hpx::lcos::local::sliding_semaphore_var` has been renamed to `hpx::sliding_semaphore_var`.
  - `hpx::lcos::local::spinlock` has been renamed to `hpx::spinlock`.
  - `hpx::lcos::local::mutex` has been renamed to `hpx::mutex`.
  - `hpx::lcos::local::timed_mutex` has been renamed to `hpx::timed_mutex`.
  - `hpx::lcos::local::no_mutex` has been renamed to `hpx::no_mutex`.
  - `hpx::lcos::local::recursive_mutex` has been renamed to `hpx::recursive_mutex`.
  - `hpx::lcos::local::shared_mutex` has been renamed to `hpx::shared_mutex`.
  - `hpx::lcos::local::upgrade_lock` has been renamed to `hpx::upgrade_lock`.
  - `hpx::lcos::local::upgrade_to_unique_lock` has been renamed to `hpx::upgrade_to_unique_lock`.
  - `hpx::lcos::local::condition_variable` has been renamed to `hpx::condition_variable`. `hpx::lcos::local::condition_variable_var` has been renamed to `hpx::condition_variable_var`.
  - `hpx::lcos::local::once_flag` has been renamed to `hpx::once_flag`, and . `hpx::lcos::local::call_once` has been renamed to `hpx::call_once`.
- The new LCI (Lightweight Communication Interface) parcelport was added that supports irregular and asynchronous applications like graph analysis, sparse linear algebra, modern parallel architectures etc. Major features include:

- Support for advanced communication primitives like two sided send/recv and one sided remote put.
- Better multi-threaded performance.
- Explicit user control of communication resource.
- Flexible signaling mechanisms (synchronizer, completion queue, active message handler).
- The following CMake flags were added, mostly to support using HPX as a backend for SHAD (<https://github.com/pnml/SHAD>). Please note that these options enable questionable functionalities, partially they even enable undefined behavior. Please only use any of them if you know what you're doing:
  - `HPX_SERIALIZATION_WITH_ALLOW_RAW_POINTER_SERIALIZATION`
  - `HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE`
  - `HPX_SERIALIZATION_WITH_ALLOW_CONST_TUPLE_MEMBERS`

## Breaking changes

- Minimum required C++ standard library is C++17.
- Support for GCC 7 and Clang 8.0.0 and below has been removed.
- CUDA version required updated to 11.4.
- CMake version required updated to 3.18.
- The default version of Asio used was updated to 1.20.0.
- The default version of APEX used was updated to 2.5.1.
- APEX version was updated to 2.5.1.
- `tagged_pair` and `tagged_tuple` were removed.
- `tag_dispatch` was renamed to `tag_invoke`.
- `hpx.max_backgroud_threads` was renamed to `hpx.parcel.max_background_threads`.
- The following CMake flags were removed after being deprecated for at least two releases:
  - `HPX_SCHEDULER_MAX_TERMINATED_THREADS`
  - `HPX_WITH_GOOGLE_PERFTOOLS`
  - `HPX_WITH_INIT_START_OVERLOADS_COMPATIBILITY`
  - `HPX_HAVE_{COROUTINE,PLUGIN}_GCC_HIDDEN_VISIBILITY`
  - `HPX_TOP_LEVEL`
  - `HPX_WITH_COMPUTE_CUDA`
  - `HPX_WITH_ASYNC_CUDA`
- `annotate_function` was renamed to `scoped_annotation`.
- `execution::transform` was renamed to `execution::then`.
- `execution::detach` was renamed to `execution::start_detached`.
- `execution::on_sender` was renamed to `execution::schedule_on`.
- `execution::just_on` was renamed to `execution::just_transfer`.
- `execution::set_done` was renamed to `execution::set_stopped`.

## Closed issues

- Issue #5871<sup>510</sup> - distributed::channel.register\_as terminates the active task.
- Issue #5856<sup>511</sup> - Performance counters do not compile
- Issue #5828<sup>512</sup> - hpx::distributed::barrier errors
- Issue #5812<sup>513</sup> - OctoTiger does not compile with HPX master and CUDA 11.5
- Issue #5784<sup>514</sup> - HPX failing with co\_await and hpx::when\_all(futures)
- Issue #5774<sup>515</sup> - CMake can't find HPXCacheVariables.cmake
- Issue #5764<sup>516</sup> - Fix HIP problem
- Issue #5724<sup>517</sup> - Missing binary filter compression header
- Issue #5721<sup>518</sup> - Cleanup after repository split
- Issue #5701<sup>519</sup> - It seems that the tcp parcelport is running, and the MPI parcelport is ignored
- Issue #5692<sup>520</sup> - Kokkos compilation fails when using both HPX and CUDA execution spaces with gcc 9.3.0
- Issue #5686<sup>521</sup> - Rename *annotate\_function*
- Issue #5668<sup>522</sup> - HPX does not detect the C++ 20 standard using gcc 11.2
- Issue #5666<sup>523</sup> - Compilation error using boost 1.76 and gcc 11.2.1
- Issue #5653<sup>524</sup> - Implement P2248 for our algorithms
- Issue #5647<sup>525</sup> - [User input needed] Remove (CUDA) compute functionality?
- Issue #5590<sup>526</sup> - hello\_world\_distributed fails on startup with HPX stable, MPICH 3.3.2, on Deep Bayou
- Issue #5570<sup>527</sup> - Rename tag\_dispatch to tag\_invoke
- Issue #5566<sup>528</sup> - can't build simple example: "Cannot use the dummy implementation of future\_then\_dispatch"
- Issue #5565<sup>529</sup> - build failure: hpx::string\_util::trim()
- Issue #5553<sup>530</sup> - Github action to validate the cff file refs #5471
- Issue #5504<sup>531</sup> - CMake does not work for HPX 1.7.0 on Piz Daint

<sup>599</sup> <https://github.com/STELLAR-GROUP/hpx/pull/5844>

- PR #5842<sup>600</sup> - change the default value of HPX\_WITH\_LCI\_TAG to v1.7
- PR #5841<sup>601</sup> - Move the split\_future facilities into the namespace hpx
- PR #5840<sup>602</sup> - wait\_xxx\_nothrow functions return whether one of the futures is exceptional
- PR #5839<sup>603</sup> - Moving a list of synchronization primitives into namespace hpx
- PR #5837<sup>604</sup> - Moving latch types to hpx and hpx::distributed namespaces
- PR #5835<sup>605</sup> - Add missing compatibility layer for id\_type::management\_type values
- PR #5834<sup>606</sup> - API docs changes
- PR #5831<sup>607</sup> - Further improvement actions to rotate
- PR #5830<sup>608</sup> - Exposing zero-copy serialization threshold through configuration option
- PR #5829<sup>609</sup> - Attempting to fix failing barrier test
- PR #5827<sup>610</sup> - Add back explicit template parameter to *ignore\_while\_checking* to compile with nvcc
- PR #5826<sup>611</sup> - Reduce number of allocations while calling `async_bulk_execute`
- PR #5825<sup>612</sup> - Steal from neighboring NUMA domain only
- PR #5823<sup>613</sup> - Remove obsolete directories and adjust build system
- PR #5822<sup>614</sup> - Clang-format remaining files
- PR #5821<sup>615</sup> - Enable permissive- flag on Windows GitHub actions builders
- PR #5820<sup>616</sup> - Convert throwmode enum to enum class
- PR #5819<sup>617</sup> - Marking customization points for intrusive\_ptr as noexcept
- PR #5818<sup>618</sup> - Unconditionally use C++17 attributes
- PR #5817<sup>619</sup> - Modernize naming modules
- PR #5816<sup>620</sup> - Modernize cache module
- PR #5815<sup>621</sup> - Reapply flyby changes from #5467
- PR #5814<sup>622</sup> - Avoid test timeouts by reducing test sizes

## 2.10.2 HPX V1.7.1 (Aug 12, 2021)

This is a bugfix release with a few minor fixes.

### General changes

- Added a CMake option to assume that all types are bitwise serializable by default: `HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE`. The default value `OFF` corresponds to the old behaviour.
- Added a version check for Asio. The minimum Asio version supported by *HPX* is 1.12.0.
- Fixed a bug affecting usage of actions, where the internals of *HPX* relied on function addresses being unique. This was fixed by relying on variable addresses being unique instead.
- Made `hpx::util::bind` more strict in checking the validity of placeholders.
- Small performance improvement to spinlocks.
- Adapted the following parallel algorithms to C++20: `inclusive_scan`, `exclusive_scan`, `transform_inclusive_scan`, `transform_exclusive_scan`.

### Breaking changes

- The experimental `hpx::execution::simdpar` execution policy (introduced in 1.7.0) was renamed to `hpx::execution::par_simd` for consistency with the other parallel policies.

### Closed issues

- Issue #5494<sup>899</sup> - Rename *simdpar* execution policy to *par\_simd*
- Issue #5488<sup>900</sup> - `hpx::util::bind` doesn't bounds-check placeholders
- Issue #5486<sup>901</sup> - Possible V1.7.1 release

### Closed pull requests

- PR #5500<sup>902</sup> - Minor bug fix in transform exclusive and inclusive scan tests

### 2.10.3 HPX V1.7.0 (Jul 14, 2021)

This release is again focused on C++20 conformance of algorithms. Additionally, many new experimental sender-based algorithms have been added based on the latest proposals.

#### General changes

- The following algorithms have been adapted to be C++20 conformant:
  - remove,
  - remove\_if,
  - remove\_copy,
  - remove\_copy\_if,
  - replace,
  - replace\_if,
  - reverse, and
  - lexicographical\_compare.
- When the compiler and standard library support the standard execution policies `std::execution::seq`, `std::execution::par`, and `std::execution::par_unseq` they can now be used in all *HPX* parallel algorithms with equivalent behaviour to the non-task policies `hpx::execution::seq`, `hpx::execution::par`, and `hpx::execution::par_unseq`.
- Vc support has been fixed, after being broken in 1.6.0. In addition, *HPX* now experimentally supports GCC’s SIMD implementation, when available. The implementation can be used through the `hpx::execution::simd` and `hpx::execution::simdpar` execution policies.
- The customization points `sync_execute`, `async_execute`, `then_execute`, `post`, `bulk_sync_execute`, `bulk_async_execute`, and `bulk_then_execute` are now implemented using `tag_dispatch` (previously `tag_invoke`). Executors can still be implemented by providing the aforementioned functions as member functions of an executor.
- New functionality, enhancements, and fixes based on P0443r14 (executors proposal) and P1897 (sender-based algorithms) have been added to the `hpx::execution::experimental` namespace. These can be accessed through the `hpx/execution.hpp` and `hpx/local/execution.hpp` headers. In particular, the following sender-based algorithms have been added:
  - detach,
  - ensure\_started,

<sup>908</sup> <https://github.com/STELLAR-GROUP/hpx/pull/5445>

<sup>909</sup> <https://github.com/STELLAR-GROUP/hpx/pull/5444>

<sup>910</sup> <https://github.com/STELLAR-GROUP/hpx/pull/5440>

<sup>911</sup> <https://github.com/STELLAR-GROUP/hpx/pull/5439>

<sup>912</sup> <https://github.com/STELLAR-GROUP/hpx/pull/5436>

- just,
- just\_on,
- let\_error,
- let\_value,
- on,
- transform, and
- when\_all.

Additionally, futures now implement the sender concept. `make_future` can be used to turn a sender into a future. All functionality is experimental and can change without notice.

- All `hpx::init` and `hpx::start` overloads now take `std::functions` instead of `hpx::util::function_nonserv`. No changes should be required in user code to accommodate this change.
- `hpx::util::unwrapping` and other related unwrapping functionality has been moved up into the `hpx` namespace. Names in `hpx::util` are still usable with a deprecation warning. This functionality can now be accessed through the `hpx/unwrap.hpp` and `hpx/local/unwrap.hpp` headers.
- The default tag for APEX has been update from 2.3.1 to 2.4.0. In particular, this fixes a bug which could lead to hangs in distributed runs.
- The dependency on Boost.Asio has been replaced with the standalone Asio available at <https://github.com/chriskohlhoff/asio>. By default, a system-installed Asio will be used. `ASIO_ROOT` can be given as a hint to tell CMake where to find Asio. Alternatively, Asio can be fetched automatically using CMake's `fetchContent` by setting `HPX_WITH_FETCH_ASIO=ON`. In general, dependencies on Boost have again been reduced.
- Modularization of the library has continued. In this release almost all functionality has been moved into modules. These changes do not generally affect user code. Warnings are still issued for headers that have moved.
- `hipBLAS` is now optional when compiling with `hipcc`. A warning instead of an error will be printed if `hipBLAS` is not found during configuration.
- Previously `HPX_COMPUTE_HOST_CODE` was defined in host code only if HPX was configured with CUDA or HIP. In this release `HPX_COMPUTE_HOST_CODE` is always defined in host code.
- An experimental `HPX_WITH_PRECOMPILED_HEADERS` CMake option has been added to use precompiled headers when building `HPX`. This option should not be used on Windows.
- Numerous bug fixes.

## Breaking changes

- The minimum required CMake version is now 3.17.
- The minimum required Boost version is now 1.71.0.
- The customization mechanism used to implement and extend sender functionality and algorithms has been renamed from `tag_invoke` to `tag_dispatch`. All customization of sender functionality should be done by overloading `tag_dispatch`.
- The following compatibility options have been removed, along with their compatibility implementations:
  - `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY`
  - `HPX_WITH_ACTION_BASE_COMPATIBILITY`
  - `HPX_WITH_EMBEDDED_THREAD_POOLS_COMPATIBILITY`
  - `HPX_WITH_POOL_EXECUTOR_COMPATIBILITY`
  - `HPX_WITH_PROMISE_ALIAS_COMPATIBILITY`
  - `HPX_WITH_REGISTER_THREAD_COMPATIBILITY`
  - `HPX_WITH_REGISTER_THREAD_OVERLOADS_COMPATIBILITY`

- HPX\_WITH\_THREAD\_AWARE\_TIMER\_COMPATIBILITY - HPX\_WITH\_THREAD\_EXECUTORS\_COMPATIBILITY - HPX\_WITH\_THREAD\_POOL\_OS\_EXECUTOR\_COMPATIBILITY
- The HPX\_WITH\_THREAD\_SCHEDULERS CMake option has been removed. All schedulers are now enabled when possible.
- HPX\_WITH\_INIT\_START\_OVERLOADS\_COMPATIBILITY has been turned off by default.

## Closed issues

## 2.10.4 HPX V1.6.0 (Feb 17, 2021)

### General changes

This release continues the focus on C++20 conformance with multiple new algorithms adapted to be C++20 conformant and becoming customization point objects (CPOs). We have also added experimental support for HIP, allowing previous CUDA features to now be compiled with `hipcc` and run on AMD GPUs.

- The following algorithms have been adapted to be C++20 conformant: `adjacent_find`, `includes`, `inplace_merge`, `is_heap`, `is_heap_until`, `is_partitioned`, `is_sorted`, `is_sorted_until`, `merge`, `set_difference`, `set_intersection`, `set_symmetric_difference`, `set_union`.
- Experimental HIP support can be enabled by compiling *HPX* with `hipcc`. All CUDA functionality in *HPX* can now be used with HIP. The HIP functionality is for the time being exposed through the same API as the CUDA functionality, i.e. no changes are required in user code. The CUDA, and now HIP, functionality is in the `hpx::cuda` namespace.
- We have added `partial_sort` based on Francisco Tapia's implementation.
- `hpx::init` and `hpx::start` gained new overloads taking an `hpx::init_params` struct in 1.5.0. All overloads not taking an `hpx::init_params` are now deprecated.
- We have added an experimental `fork_join_executor`. This executor can be used for OpenMP-style fork-join parallelism, where the latency of a parallel region is important for performance.
- The `parallel_executor` now uses a hierarchical spawning scheme for bulk execution, which improves data locality and performance.
- `hpx::dataflow` can now be used with executors that inject additional parameters into the call of the user-provided function.
- We have added experimental support for properties as proposed in P2220<sup>1159</sup>. Currently the only supported property is the scheduling hint on `parallel_executor`.
- `hpx::util::annotated_function` can now be passed a dynamically generated `std::string`.
- In moving functionality to new namespaces, old names have been deprecated. A deprecation warning will be issued if you are using deprecated functionality, with instructions on how to correct or ignore the warning.
- We have removed all support for C and Fortran from our build system.
- We have further reduced the use of Boost types within *HPX* (`boost::system::error_code` and `boost::detail::spinlock`).
- We have enabled more warnings in our CI builds (unused variables and unused typedefs).

### Breaking changes

- `hpxMP` support has been completely removed.
- The verbs `parcelport` has been removed.
- The following compatibility options have been disabled by default: `HPX_WITH_ACTION_BASE_COMPATIBILITY`, `HPX_WITH_REGISTER_THREAD_COMPATIBILITY`, `HPX_WITH_PROMISE_ALIAS_COMPATIBILITY`, `HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY`, `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY`, `HPX_WITH_EMBEDDED_THREAD_POOLS_COMPATIBILITY`, `HPX_WITH_THREAD_POOL_OS_EXECUTOR_COMPATIBILITY`, `HPX_WITH_THREAD_EXECUTORS_COMPATIBILITY`, `HPX_THREAD_AWARE_TIMER_COMPATIBILITY`, `HPX_WITH_POOL_EXECUTOR_COMPATIBILITY`. Unless noted here, the above functionalities do not come with replacements. Unscoped enumerations have been replaced by scoped enumerations. Previously

---

<sup>1159</sup> <https://wg21.link/p2220>

deprecated unscoped enumerations are disabled by `HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY`. Newly deprecated unscoped enumerations have been given deprecation warnings and replaced by scoped enumerations. `hpx::promise` has been replaced with `hpx::distributed::promise`. `hpx::program_options` is a drop-in replacement for `boost::program_options`. `hpx::execution::parallel_executor` now has constructors which take a thread pool, covering the use case of `hpx::threads::executors::pool_executor`. A pool can be supplied with `hpx::resource::get_thread_pool`.

## Closed issues

- Issue #5148<sup>[1160](#)</sup> - `runtime_support.hpp` does not work with newer clang
- Issue #5147<sup>[1161](#)</sup> - Wrong results with parallel reduce
- Issue #5129<sup>[1162](#)</sup> - Missing specialization for `std::hash<hpx::thread::id>`
- Issue #5126<sup>[1163](#)</sup> - Use `std::string` for task annotations
- Issue #5115<sup>[1164](#)</sup> - Don't expect hwloc to always report Cores
- Issue #5113<sup>[1165](#)</sup> - Handle threadmanager exceptions during startup
- Issue #5112<sup>[1166](#)</sup> - libatomic problems causing unexpected fails
- Issue #5089<sup>[1167](#)</sup> - Remove non-BSL files
- Issue #5088<sup>[1168](#)</sup> - Unwrapping problem
- Issue #5087<sup>[1169](#)</sup> - Remove hpxMP support
- Issue #5077<sup>[1170](#)</sup> - PAPI counters are not accessible when HPX is installed
- Issue #5075<sup>[1171](#)</sup> - Make the structs in all `iter_sent.hpp` lower case
- Issue #5067<sup>[1172](#)</sup> - Bug `string_util/split.hpp`
- Issue #5049<sup>[1173](#)</sup> - Change back the hipcc jenkins config to the fury partition on rostam
- Issue #5038<sup>[1174](#)</sup> - Not all examples link in the latest HPX master
- Issue #5035<sup>[1175](#)</sup> - Build with `HPX_WITH_EXAMPLES` fails
- Issue #5019<sup>[1176](#)</sup> - Broken help string for hpx
- Issue #5016<sup>[1177](#)</sup> - `hpx::parallel::fill` fails compiling
- Issue #5014<sup>[1178](#)</sup> - Rename all .cc to .cpp and .hh to .hpp

## 2.10.5 HPX V1.5.1 (Sep 30, 2020)

### General changes

This is a patch release. It contains the following changes:

- Remove restriction on suspending runtime with multiple localities, users are now responsible for synchronizing work between localities before suspending.
- Fixes several compilation problems and warnings.
- Adds notes in the documentation explaining how to cite HPX.

## 2.10.6 HPX V1.5.0 (Sep 02, 2020)

### General changes

The main focus of this release is on APIs and C++20 conformance. We have added many new C++20 features and adapted multiple algorithms to be fully C++20 conformant. As part of the modularization we have begun specifying the public API of *HPX* in terms of headers and functionality, and aligning it more closely to the C++ standard. All non-distributed modules are now in place, along with an experimental option to completely disable distributed features in *HPX*. We have also added experimental asynchronous MPI and CUDA executors. Lastly this release introduces CMake targets for depending projects, performance improvements, and many bug fixes.

- We have added the C++20 features `hpx::jthread` and `hpx::stop_token`. `hpx::condition_variable_any` now exposes new functions supporting `hpx::stop_token`.
- We have added `hpx::stable_sort` based on Francisco Tapia’s implementation.

<sup>1334</sup> <https://github.com/STELLAR-GROUP/hpx/issues/4971>

<sup>1335</sup> <https://github.com/STELLAR-GROUP/hpx/issues/4950>

<sup>1338</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4982>

<sup>1339</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4981>

<sup>1340</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4974>

<sup>1341</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4972>

<sup>1342</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4963>

<sup>1343</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4951>

<sup>1344</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4946>

<sup>1345</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4944>

<sup>1346</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4941>

<sup>1347</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4939>

- We have adapted existing synchronization primitives to be fully conformant C++20: `hpx::barrier`, `hpx::latch`, `hpx::counting_semaphore`, and `hpx::binary_semaphore`.
- We have started using customization point objects (CPOs) to make the corresponding algorithms fully conformant to C++20 as well as to make algorithm extension easier for the user. `all_of/any_of/none_of`, `copy`, `count`, `destroy`, `equal`, `fill`, `find`, `for_each`, `generate`, `mismatch`, `move`, `reduce`, `transform_reduce` are using those CPOs (all in namespace `hpx`). We also have adapted their corresponding `hpx::ranges` versions to be conforming to C++20 in this release.
- We have adapted support for `co_await` to C++20, in addition to `hpx::future` it now also supports `hpx::shared_future`. We have also added allocator support for futures returned by `co_return`. It is no longer in the `experimental` namespace.
- We added serialization support for `std::variant` and `std::tuple`.
- `result_of` and `is_callable` are now deprecated and replaced by `invoke_result` and `is_invocable` to conform to C++20.
- We continued with the modularization, making it easier for us to add the new experimental `HPX_WITH_DISTRIBUTED_RUNTIME` CMake option (see below). An significant amount of headers have been deprecated. We adapted the namespaces and headers we could to be closer to the standard ones (*Public API*). Depending code should still compile, however warnings are now generated instructing to change the include statements accordingly.
- It is now possible to have a basic CUDA support including a helper function to get a future from a CUDA stream and target handling. They are available under the `hpx::cuda::experimental` namespace and they can be enabled with the `-DHPX_WITH_ASYNC_CUDA=ON` CMake option.
- We added a new `hpx::mpi::experimental` namespace for getting futures from an asynchronous MPI call and a new minimal MPI executor `hpx::mpi::experimental::executor`. These can be enabled with the `-DHPX_WITH_ASYNC_MPI=On` CMake option.
- A polymorphic executor has been implemented to reduce compile times as a function accepting executors can potentially be instantiated only once instead of multiple times with different executors. It accepts the function signature as a template argument. It needs to be constructed from any other executor. Please note, that the function signatures that can be scheduled using `then_execute`, `bulk_sync_execute`, `bulk_async_execute` and `bulk_then_execute` are slightly different (See the comment in PR #4514<sup>1348</sup> for more details).
- The underlying executor of `block_executor` has been updated to a newer one.
- We have added a parameter to `auto_chunk_size` to control the amount of iterations to measure.
- All executor parameter hooks can now be exposed through the executor itself. This will allow to deprecate the `.with()` functionality on execution policies in the future. This is also a first step towards simplifying our executor APIs in preparation for the upcoming C++23 executors (senders/receivers).
- We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`. Please note this is a breaking change without backwards-compatibility option. We have converted all of those APIs to be based on customization point objects. Two new executors have been added to enable easy integration of the existing resiliency features with other facilities (like the parallel algorithms): `replay_executor` and `replicate_executor`.
- We have added performance counters type information (`aggregating`, `monotonically increasing`, `average count`, `average timer`, etc.).
- HPX threads are now re-scheduled on the same worker thread they were suspended on to avoid cache misses from moving from one thread to the other. This behavior doesn't prevent the thread from being stolen, however.
- We have added a new configuration option `hpx.exception_verbosity` to allow to control the level of verbosity of the exceptions (3 levels available).

---

<sup>1348</sup> <https://github.com/STELLAR-GROUP/hpx/pull/4514>

- `broadcast_to`, `broadcast_from`, `scatter_to` and `scatter_from` have been added to the collectives, modernization of `gather_here` and `gather_there` with futures taken by rvalue references. See the breaking change on `all_to_all` in the next section. None of the collectives need supporting macros anymore (e.g. specifying the data types used for a collective operation using `HPX_REGISTER_ALLGATHER` and similar is not needed anymore).
- New API functions have been added: a) to get the number of cores which are idle (`hpx::get_idle_core_count`) and b) returning a bitmask representing the currently idle cores (`hpx::get_idle_core_mask`).
- We have added an experimental option to only enable the local runtime, you can disable the distributed runtime with `HPX_WITH_DISTRIBUTED_RUNTIME=OFF`. You can also enable the local runtime by using the `--hpx:local` runtime option.
- We fixed task annotations for actions.
- The alias `hpx::promise` to `hpx::lcos::promise` is now deprecated. You can use `hpx::lcos::promise` directly instead. `hpx::promise` will refer to the local-only promise in the future.
- We have added a `prepare_checkpoint` API function that calculates the amount of necessary buffer space for a particular set of arguments checkpointed.
- We have added `hpx::upgrade_lock` and `hpx::upgrade_to_unique_lock`, which make `hpx::shared_mutex` (and similar) usable in more flexible ways.
- We have changed the CMake targets exposed to the user, it now includes `HPX::hpx`, `HPX::wrap_main` (int `main` as the first `HPX` thread of the application, see [Starting the HPX runtime](#)), `HPX::plugin`, `HPX::component`. The CMake variables `HPX_INCLUDE_DIRS` and `HPX_LIBRARIES` are deprecated and will be removed in a future release, you should now link directly to the `HPX::hpx` CMake target.
- A new example is demonstrating how to create and use a wrapping executor (`quickstart/executor_with_thread_hooks.cpp`)
- A new example is demonstrating how to disable thread stealing during the execution of parallel algorithms (`quickstart/disable_thread_stealing_executor.cpp`)
- We now require for our CMake build system configuration files to be formatted using `cmake-format`.
- We have removed more dependencies on various Boost libraries.
- We have added an experimental option enabling unity builds of HPX using the `-DHPX_WITH_UNITY_BUILD=On` CMake option.
- Many bug fixes.

## Breaking changes

- `HPX` now requires a C++14 capable compiler. We have set the `HPX` C++ standard automatically to C++14 and if it needs to be set explicitly, it should be specified through the `CMAKE_CXX_STANDARD` setting as mandated by CMake. The `HPX_WITH_CXX*` variables are now deprecated and will be removed in the future.
- Building and using HPX is now supported only when using CMake V3.13 or later, Boost V1.64 or newer, and when compiling with clang V5, gcc V7, or VS2019, or later. Other compilers might still work but have not been tested thoroughly.
- We have added a `hpx::init_params` struct to pass parameters for `HPX` initialization e.g. the resource partitioner callback to initialize thread pools ([Using the resource partitioner](#)).
- The `all_to_all` algorithm is renamed to `all_gather`, and the new `all_to_all` algorithm is not compatible with the old one.
- We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`.

## Closed pull requests

- PR #4936<sup>1438</sup> - Minor documentation fixes part 2
- PR #4935<sup>1439</sup> - Add copyright and license to joss paper file
- PR #4934<sup>1440</sup> - Adding Semicolon in Documentation
- PR #4932<sup>1441</sup> - Fixing compiler warnings
- PR #4931<sup>1442</sup> - Small documentation formatting fixes
- PR #4930<sup>1443</sup> - Documentation Distributed HPX applications localvv with local\_vv
- PR #4929<sup>1444</sup> - Add final version of the JOSS paper
- PR #4928<sup>1445</sup> - Add HPX\_NODISCARD to enable\_user\_polling structs
- PR #4926<sup>1446</sup> - Rename distributed\_executors module to executors\_distributed
- PR #4925<sup>1447</sup> - Making transform\_reduce conforming to C++20
- PR #4923<sup>1448</sup> - Don't acquire lock if not needed
- PR #4921<sup>1449</sup> - Update the release notes for the release candidate 3
- PR #4920<sup>1450</sup> - Disable libcds release
- PR #4919<sup>1451</sup> - Make cuda event pool dynamic instead of fixed size
- PR #4917<sup>1452</sup> - Move chrono functionality to hpx::chrono namespace
- PR #4916<sup>1453</sup> - HPX\_HAVE\_DEPRECATED\_WARNINGS needs to be set even when disabled
- PR #4915<sup>1454</sup> - Moving more action related files to actions modules
- PR #4914<sup>1455</sup> - Add alias targets with namespaces used for exporting
- PR #4912<sup>1456</sup> - Aggregate initialize CPOs
- PR #4910<sup>1457</sup> - Explicitly specify hwloc root on Jenkins CSCS builds
- PR #4908<sup>1458</sup> - Fix algorithms documentation
- PR #4907<sup>1459</sup> - Remove HPX::hpx\_no\_wrap\_main target

- PR #4906<sup>1460</sup> - Fixing unused variable warning
- PR #4905<sup>1461</sup> - Adding specializations for simple for\_loops
- PR #4904<sup>1462</sup> - Update boost to 1.74.0 for the newest jenkins configs
- PR #4903<sup>1463</sup> - Hide GITHUB\_TOKEN environment variables from environment variable output
- PR #4902<sup>1464</sup> - Cancel previous pull requests builds before starting a new one with Jenkins
- PR #4901<sup>1465</sup> - Update public API list with updated algorithms
- PR #4899<sup>1466</sup> - Suggested changes for HPX V1.5 release notes
- PR #4898<sup>1467</sup> - Minor tweak to hpx::equal implementation
- PR #4896<sup>1468</sup> - Making generate() and generate\_n conforming to C++20
- PR #4895<sup>1469</sup> - Update apex tag
- PR #4894<sup>1470</sup> - Fix exception handling for tasks
- PR #4893<sup>1471</sup> - Remove last use of std::result\_of, removed in C++20
- PR #4892<sup>1472</sup> - Adding replay\_executor and replicate\_executor
- PR #4889<sup>1473</sup> - Restore old behaviour of not requiring linking to hpx\_wrap when HPX\_WITH\_DYNAMIC\_HPX\_MAIN=OFF
- PR #4887<sup>1474</sup> - Making sure remotely thrown (non-hpx) exceptions are properly marshaled back to invocation site
- PR #4885<sup>1475</sup> - Adapting hpx::find and friends to C++20
- PR #4884<sup>1476</sup> - Adapting mismatch to C++20
- PR #4883<sup>1477</sup> - Adapting hpx::equal to be conforming to C++20
- PR #4882<sup>1478</sup> - Fixing exception handling for hpx::copy and adding missing tests
- PR #4881<sup>1479</sup> - Adds different runtime exception when registering thread with the HPX runtime
- PR #4876<sup>1480</sup> - Adding example demonstrating how to disable thread stealing during the execution of parallel algorithms
- PR #4874<sup>1481</sup> - Adding non-policy tests to all\_of, any\_of, and none\_of

- PR #4843<sup>1505</sup> - Remove dependency on various Boost headers
- PR #4841<sup>1506</sup> - Rearrange public API headers
- PR #4840<sup>1507</sup> - Fixing TSS problems during thread termination
- PR #4839<sup>1508</sup> - Fix async\_cuda build problems when distributed runtime is disabled
- PR #4837<sup>1509</sup> - Restore compatibility for old (now deprecated) copy algorithms
- PR #4836<sup>1510</sup> - Adding CPOs for hpx::reduce
- PR #4835<sup>1511</sup> - Remove *using util::result\_of* from namespace hpx
- PR #4834<sup>1512</sup> - Fixing the calculation of the number of idle cores and the corresponding idle masks
- PR #4833<sup>1513</sup> - Allow thread function destructors to yield
- PR #4832<sup>1514</sup> - Fixing assertion in split\_gids and memory leaks in 1d\_stencil\_7
- PR #4831<sup>1515</sup> - Making sure MPI\_CXX\_COMPILE\_FLAGS is interpreted as a sequence of options
- PR #4830<sup>1516</sup> - Update documentation on using HPX::wrap\_main
- PR #4827<sup>1517</sup> - Update clang-newest configuration to use clang 10
- PR #4826<sup>1518</sup> - Add Jenkins configuration for rostam
- PR #4825<sup>1519</sup> - Move all CUDA functionality to hpx::cuda::experimental namespace
- PR #4824<sup>1520</sup> - Add support for building master/release branches to Jenkins configuration
- PR #4821<sup>1521</sup> - Implement customization point for hpx::copy and hpx::ranges::copy
- PR #4819<sup>1522</sup> - Allow finding Boost components before finding HPX
- PR #4817<sup>1523</sup> - Adding range version of stable sort
- PR #4815<sup>1524</sup> - Fix a wrong #ifdef for IO/TIMER pools causing build errors
- PR #4814<sup>1525</sup> - Replace hpx::function\_nonser with std::function in error module
- PR #4809<sup>1526</sup> - Foreach adapt
- PR #4808<sup>1527</sup> - Make internal algorithms functions const

- PR #4807<sup>1528</sup> - Add Jenkins configuration for running on Piz Daint
- PR #4806<sup>1529</sup> - Update documentation links to new domain name
- PR #4805<sup>1530</sup> - Applying changes that resolve time complexity issues in sort
- PR #4803<sup>1531</sup> - Adding implementation of stable\_sort
- PR #4802<sup>1532</sup> - Fix datapar header paths
- PR #4801<sup>1533</sup> - Replace boost::shared\_array<T> with std::shared\_ptr<T[]> if supported
- PR #4799<sup>1534</sup> - Fixing #include paths in compatibility headers
- PR #4798<sup>1535</sup> - Include the main module header (fixes partially #4488)
- PR #4797<sup>1536</sup> - Change cmake targets
- PR #4794<sup>1537</sup> - Removing 128bit integer emulation
- PR #4793<sup>1538</sup> - Make sure global variable is handled properly
- PR #4792<sup>1539</sup> - Replace enable\_if with **HPX\_CONCEPT\_REQUIRE**s and add is\_sentinel\_for constraint
- PR #4790<sup>1540</sup> - Move deprecation warnings from base template to template specializations for result\_of etc. structs
- PR #4789<sup>1541</sup> - Fix hangs during assertion handling and distributed runtime construction
- PR #4788<sup>1542</sup> - Fixing inclusive transform scan algorithm to properly handle initial value
- PR #4785<sup>1543</sup> - Fixing barrier test
- PR #4784<sup>1544</sup> - Fixing deleter argument bindings in serialize\_buffer
- PR #4783<sup>1545</sup> - Add coveralls badge
- PR #4782<sup>1546</sup> - Make header tests parallel again
- PR #4780<sup>1547</sup> - Remove outdated comment about hpx::stop in documentation
- PR #4776<sup>1548</sup> - debug print improvements
- PR #4775<sup>1549</sup> - Checkpoint cleanup
- PR #4771<sup>1550</sup> - Fix compilation with HPX\_WITH\_NETWORKING=OFF

- PR #4563<sup>1666</sup> - fix CMake option typo
- PR #4562<sup>1667</sup> - Unregister lock earlier to avoid holding it while suspending
- PR #4561<sup>1668</sup> - Adding test macros supporting custom output stream
- PR #4560<sup>1669</sup> - Making sure hash\_any::operator()() is linked into core library
- PR #4559<sup>1670</sup> - Fixing compilation if HPX\_WITH\_THREAD\_BACKTRACE\_ON\_SUSPENSION=On
- PR #4557<sup>1671</sup> - Improve spinlock implementation to perform better in high-contention situations
- PR #4553<sup>1672</sup> - Fix a runtime\_ptr problem at shutdown when apex is enabled
- PR #4552<sup>1673</sup> - Add configuration option for making exceptions less noisy
- PR #4551<sup>1674</sup> - Clean up thread creation parameters
- PR #4549<sup>1675</sup> - Test FetchContent build on GitHub actions
- PR #4548<sup>1676</sup> - Fix stack size
- PR #4545<sup>1677</sup> - Fix header tests
- PR #4544<sup>1678</sup> - Fix a typo in sanitizer build
- PR #4541<sup>1679</sup> - Add API to check if a thread pool exists
- PR #4540<sup>1680</sup> - Making sure MPI support is enabled if MPI futures are used but networking is disabled
- PR #4538<sup>1681</sup> - Move channel documentation examples to examples directory
- PR #4536<sup>1682</sup> - Add generic allocator for execution policies
- PR #4534<sup>1683</sup> - Enable compatibility headers for thread\_executors module
- PR #4532<sup>1684</sup> - Fixing broken url in README.rst
- PR #4531<sup>1685</sup> - Update scripts
- PR #4530<sup>1686</sup> - Make sure module API docs show up in correct order
- PR #4529<sup>1687</sup> - Adding missing template code to module creation script
- PR #4528<sup>1688</sup> - Make sure version module uses HPX's binary dir, not the parent's

## 2.10.7 HPX V1.4.1 (Feb 12, 2020)

### General changes

This is a bugfix release. It contains the following changes:

- Fix compilation issues on Windows, macOS, FreeBSD, and with gcc 10
- Install missing pdb files on Windows
- Allow running tests using an installed version of *HPX*
- Skip MPI finalization if HPX has not initialized MPI
- Give a hard error when attempting to use IO counters on Windows

### Closed issues

- Issue #4320<sup>1847</sup> - HPX 1.4.0 does not compile with gcc 10
- Issue #4336<sup>1848</sup> - Building HPX 1.4.0 with IO Counters breaks (Windows)
- Issue #4334<sup>1849</sup> - HPX Debug and RelWithDebInfo builds on Windows not installing .pdb files
- Issue #4322<sup>1850</sup> - Undefine VT1 and VT2 after boost includes
- Issue #4314<sup>1851</sup> - Compile error on 1.4.0
- Issue #4307<sup>1852</sup> - ld: error: duplicate symbol: freebsd\_environ

### Closed pull requests

## 2.10.8 HPX V1.4.0 (January 15, 2020)

### General changes

- We have added the collectives `all_to_all` and `all_reduce`.
- We have added APIs for resiliency, which allows replication and replay for failed tasks. See the [documentation](#) for more details.
- Components can now be checkpointed.
- Performance improvements to schedulers and coroutines. A significant change is the addition of stackless coroutines. These are to be used for tasks that do not need to be suspended and can reduce overheads noticeably in applications with short tasks. A stackless coroutine can be created with the new stack size `thread_stacksize_nostack`.
- We have added an implementation of `unique_any`, which is a non-copyable version of `any`.
- The `shared_priority_queue_scheduler` has been improved. It now has lower overheads than the default scheduler in many situations. Unlike the default scheduler it fully supports NUMA scheduling hints. Enable it with the command line option `--hpx:queuing=shared-priority`. This scheduler should still be considered experimental, but its use is encouraged in real applications to help us make it production ready.
- We have added the performance counters `background-receive-duration` and `background-receive-overhead` for inspecting the time and overhead spent on receiving parcels in the background.
- Compilation time has been further improved when `HPX_WITH_NETWORKING=OFF`.
- We no longer require compiled Boost dependencies in certain configurations. This requires at least Boost 1.70, compiling on x86 with GCC 9, clang (libc++) 9, or VS2019 in C++17 mode. The dependency on Boost.Filesystem can explicitly be turned on with `HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY=ON` (it is off by default if the standard library supports `std::filesystem`). Boost.ProgramOptions has been copied into the HPX repository. We have a compatibility layer for users who must explicitly use Boost.ProgramOptions instead of the ProgramOptions provided by HPX. To remove the dependency `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY` must be explicitly set to OFF. This option will be removed in a future release. We have also removed several other header-only dependencies on Boost.
- It is now possible to use the process affinity mask set by tools like `numactl` and various batch environments with the command line option `--hpx:use-process-mask`. Enabling this option implies `--hpx:ignore-batch-env`.
- It is now possible to create standalone thread pools without starting the runtime. See the `standalone_thread_pool_executor.cpp` test in the `execution` module for an example.
- Tasks annotated with `hpx::util::annotated_function` now have their correct name when using APEX to generate OTF2 files.
- Cloning of APEX was defective in previous releases (it required manual intervention to check out the correct tag or branch). This has been fixed.
- The option `HPX_WITH_MORE_THAN_64_THREADS` is now ignored and will be removed in a future release. The value is instead derived directly from `HPX_WITH_MAX_CPU_COUNT` option.
- We have deprecated compiling in C++11 mode. The next release will require a C++14 capable compiler.
- We have deprecated support for the Vc library. This option will be replaced with SIMD support from the standard library in a future release.

- We have significantly refactored our CMake setup. This is intended to be a non-breaking change and will allow for using HPX through CMake targets in the future.
- We have continued modularizing the HPX library. In the process we have rearranged many header files into module-specific directories. All moved headers have compatibility headers which forward from the old location to the new location, together with a deprecation warning. The compatibility headers will eventually be removed.
- We now enforce formatting with `clang-format` on the majority of our source files.
- We have added SPDX license tags to all files.
- Many bugfixes.

### Breaking changes

- The `HPX_WITH_THREAD_COMPATIBILITY` option and the associated compatibility layer has been removed.
- The `HPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY` option and the associated compatibility layer has been removed.
- The `HPX_WITH_UNWRAPPED_COMPATIBILITY` option and the associated compatibility layer has been removed.

- PR #3159<sup>2227</sup> - Support Checkpointing Components

## 2.10.9 HPX V1.3.0 (May 23, 2019)

### General changes

- Performance improvements: the schedulers have significantly reduced overheads from removing false sharing and the parallel executor has been updated to create fewer futures.
- HPX now defaults to not turning on networking when running on one locality. This means that you can run multiple instances on the same system without adding command line options.
- Multiple issues reported by Clang sanitizers have been fixed.
- We have added (back) single-page HTML documentation and PDF documentation.
- We have started modularizing the HPX library. This is useful both for developers and users. In the long term users will be able to consume only parts of the HPX libraries if they do not require all the functionality that HPX currently provides.
- We have added an implementation of `function_ref`.
- The `barrier` and `latch` classes have gained a few additional member functions.

<sup>2227</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3159>

## Breaking changes

- Executable and library targets are now created without the \_exe and \_lib suffix respectively. For example, the target 1d\_stencil\_1\_exe is now simply called 1d\_stencil\_1.
- We have removed the following deprecated functionality: queue, scoped\_unlock, and support for input iterators in algorithms.
- We have turned off the compatibility layer for unwrapped by default. The functionality will be removed in the next release. The option can still be turned on using the CMake<sup>2228</sup> option HPX\_WITH\_UNWRAPPED\_SUPPORT. Likewise, inclusive\_scan compatibility overloads have been turned off by default. They can still be turned on with HPX\_WITH\_INCLUSIVE\_SCAN\_COMPATIBILITY.
- The minimum compiler and dependency versions have been updated. We now support GCC from version 5 onwards, Clang from version 4 onwards, and Boost from version 1.61.0 onwards.
- The headers for preprocessor macros have moved as a result of the functionality being moved to a separate module. The old headers are deprecated and will be removed in a future version of HPX. You can turn off the warnings by setting HPX\_PREPROCESSOR\_WITH\_DEPRECATED\_WARNINGS=OFF or turn off the compatibility headers completely with HPX\_PREPROCESSOR\_WITH\_COMPATIBILITY\_HEADERS=OFF.

## Closed issues

- Issue #3863<sup>2229</sup> - shouldn't “-faligned-new” be a usage requirement?
- Issue #3841<sup>2230</sup> - Build error with msvc 19 caused by SFINAE and C++17
- Issue #3836<sup>2231</sup> - master branch does not build with idle rate counters enabled

## 2.10.10 HPX V1.2.1 (Feb 19, 2019)

### General changes

This is a bugfix release. It contains the following changes:

- Fix compilation on ARM, s390x and 32-bit architectures.
- Fix a critical bug in the future implementation.
- Fix several problems in the CMake configuration which affects external projects.
- Add support for Boost 1.69.0.

### Closed issues

## 2.10.11 HPX V1.2.0 (Nov 12, 2018)

### General changes

Here are some of the main highlights and changes for this release:

- Thanks to the work of our Google Summer of Code student, Nikunj Gupta, we now have a new implementation of `hpx_main.hpp` on supported platforms (Linux, BSD and MacOS). This is intended to be a less fragile drop-in replacement for the old implementation relying on preprocessor macros. The new implementation does not require changes if you are using the CMake<sup>2522</sup> or `pkg-config`. The old behaviour can be restored by setting `HPX_WITH_DYNAMIC_HPX_MAIN=OFF` during CMake<sup>2523</sup> configuration. The implementation on Windows is unchanged.
- We have added functionality to allow passing scheduling hints to our schedulers. These will allow us to create executors that for example target a specific NUMA domain or allow for *HPX* threads to be pinned to a particular worker thread.
- We have significantly improved the performance of our futures implementation by making the shared state atomic.
- We have replaced Boostbook by Sphinx for our documentation. This means the documentation is easier to navigate with built-in search and table of contents. We have also added a quick start section and restructured the documentation to be easier to follow for new users.

<sup>2510</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3695>

<sup>2511</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3666>

<sup>2512</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3663>

<sup>2513</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3648>

<sup>2514</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3647>

<sup>2515</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3611>

<sup>2516</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3595>

<sup>2517</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3593>

<sup>2518</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3591>

<sup>2519</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3558>

<sup>2520</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3555>

<sup>2521</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3551>

<sup>2522</sup> <https://www.cmake.org>

<sup>2523</sup> <https://www.cmake.org>

- We have added a new option to the `--hpx:threads` command line option. It is now possible to use `cores` to tell *HPX* to only use one worker thread per core, unlike the existing option `a11` which uses one worker thread per processing unit (processing unit can be a hyperthread if hyperthreads are available). The default value of `--hpx:threads` has also been changed to `cores` as this leads to better performance in most cases.
- All command line options can now be passed alongside configuration options when initializing *HPX*. This means that some options that were previously only available on the command line can now be set as configuration options.
- HPXMP is a portable, scalable, and flexible application programming interface using the OpenMP specification that supports multi-platform shared memory multiprocessing programming in C and C++. HPXMP can be enabled within *HPX* by setting `DHPX_WITH_HPXMP=ON` during [CMake<sup>2524</sup>](#) configuration.
- Two new performance counters were added for measuring the time spent doing background work. `/threads/time/background-work-duration` returns the time spent doing background on a given thread or locality, while `/threads/time/background-overhead` returns the fraction of time spent doing background work with respect to the overall time spent running the scheduler. The new performance counters are disabled by default and can be turned on by setting `HPX_WITH_BACKGROUND_THREAD_COUNTERS=ON` during [CMake<sup>2525</sup>](#) configuration.
- The idling behaviour of *HPX* has been tweaked to allow for faster idling. This is useful in interactive applications where the *HPX* worker threads may not have work all the time. This behaviour can be tweaked and turned off as before with `HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF=OFF` during [CMake<sup>2526</sup>](#) configuration.
- It is now possible to register callback functions for *HPX* worker thread events. Callbacks can be registered for starting and stopping worker threads, and for when errors occur.

## Breaking changes

- The implementation of `hpx_main.hpp` has changed. If you are using custom Makefiles you will need to make changes. Please see the documentation on [using Makefiles](#) for more details.
- The default value of `--hpx:threads` has changed from `a11` to `cores`. The new option `cores` only starts one worker thread per core.
- We have dropped support for Boost 1.56 and 1.57. The minimal version of Boost we now test is 1.58.
- Our `boost::format`-based formatting implementation has been revised and replaced with a custom implementation. This changes the formatting syntax and requires changes if you are relying on `hpx::util::format` or `hpx::util::format_to`. The pull request for this change contains more information: [PR #3266<sup>2527</sup>](#).
- The following deprecated options have now been completely removed: `HPX_WITH_ASYNC_FUNCTION_COMPATIBILITY`, `HPX_WITH_LOCAL_DATAFLOW`, `HPX_WITH_GENERIC_EXECUTION_POLICY`, `HPX_WITH_BOOST_CHRONO_COMPATIBILITY`, `HPX_WITH_EXECUTOR_COMPATIBILITY`, `HPX_WITH_EXECUTION_POLICY_COMPATIBILITY`, and `HPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY`.

## 2.10.12 HPX V1.1.0 (Mar 24, 2018)

### General changes

Here are some of the main highlights and changes for this release (in no particular order):

- We have changed the way *HPX* manages the processing units on a node. We do not longer implicitly bind all available cores to a single thread pool. The user has now full control over what processing units are bound to what thread pool, each with a separate scheduler. It is now also possible to create your own scheduler implementation and control what processing units this scheduler should use. We added the `hpx::resource::partitioner` that manages all available processing units and assigns resources to the used thread pools. Thread pools can be now be suspended/resumed independently. This functionality helps in running *HPX* concurrently to code that is directly relying on OpenMP<sup>2784</sup> and/or MPI<sup>2785</sup>.
- We have continued to implement various parallel algorithms. *HPX* now almost completely implements all of the parallel algorithms as specified by the C++17 Standard<sup>2786</sup>. We have also continued to implement these algorithms for the distributed use case (for segmented data structures, such as `hpx::partitioned_vector`).
- Added a compatibility layer for `std::thread`, `std::mutex`, and `std::condition_variable` allowing for the code to use those facilities where available and to fall back to the corresponding Boost facilities otherwise. The CMake<sup>2787</sup> configuration option `-DHPX_WITH_THREAD_COMPATIBILITY=On` can be used to force using the Boost equivalents.
- The parameter sequence for the `hpx::parallel::transform_inclusive_scan` overload taking one iterator range has changed (again) to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing `-DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake<sup>2788</sup>.
- The parameter sequence for the `hpx::parallel::inclusive_scan` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing `-DHPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY=On` to CMake.
- Added a helper facility `hpx::local_new` which is equivalent to `hpx::new_` except that it creates components locally only. As a consequence, the used component constructor may accept non-serializable argument types and/or non-const references or pointers.
- Removed the (broken) component type `hpx::lcos::queue<T>`. The old type is still available at configure time by passing `-DHPX_WITH_QUEUE_COMPATIBILITY=On` to CMake.

<sup>2783</sup> <https://github.com/STELLAR-GROUP/hpx/pull/3036>

<sup>2784</sup> <https://openmp.org/wp/>

<sup>2785</sup> [https://en.wikipedia.org/wiki/Message\\_Passing\\_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

<sup>2786</sup> <http://www.open-std.org/jtc1/sc22/wg21>

<sup>2787</sup> <https://www.cmake.org>

<sup>2788</sup> <https://www.cmake.org>

- The parallel algorithms adopted for C++17 restrict the iterator categories usable with those to at least forward iterators. Our implementation of the parallel algorithms was supporting input iterators (and output iterators) as well by simply falling back to sequential execution. We have now made our implementations conforming by requiring at least forward iterators. In order to enable the old behavior use the compatibility option `-DHPX_WITH_ALGORITHM_INPUT_ITERATOR_SUPPORT=On` on the [CMake](#)<sup>2789</sup> command line.
- We have added the functionalities allowing for LCOs being implemented using (simple) components. Before LCOs had to always be implemented using managed components.
- User defined components don't have to be default-constructible anymore. Return types from actions don't have to be default-constructible anymore either. Our serialization layer now in general supports non-default-constructible types.
- We have added a new launch policy `hpx::launch::lazy` that allows one to defer the decision on what launch policy to use to the point of execution. This policy is initialized with a function (object) that – when invoked – is expected to produce the desired launch policy.

## Breaking changes

- We have dropped support for the gcc compiler version V4.8. The minimal gcc version we now test on is gcc V4.9. The minimally required version of [CMake](#)<sup>2790</sup> is now V3.3.2.
- We have dropped support for the Visual Studio 2013 compiler version. The minimal Visual Studio version we now test on is Visual Studio 2015.5.
- We have dropped support for the Boost V1.51-V1.54. The minimal version of Boost we now test is Boost V1.55.
- We have dropped support for the `hpx::util::unwrapped` API. `hpx::util::unwrapped` will stay functional to some degree, until it finally gets removed in a later version of HPX. The functional usage of `hpx::util::unwrapped` should be changed to the new `hpx::util::unwrapping` function whereas the immediate usage should be replaced to `hpx::util::unwrap`.
- The performance counter names referring to properties as exposed by the threading subsystem have changes as those now additionally have to specify the thread-pool. See the corresponding documentation for more details.
- The overloads of `hpx::async` that invoke an action do not perform implicit unwrapping of the returned future anymore in case the invoked function does return a future in the first place. In this case `hpx::async` now returns a `hpx::future<future<T>>` making its behavior conforming to its local counterpart.
- We have replaced the use of `boost::exception_ptr` in our APIs with the equivalent `std::exception_ptr`. Please change your codes accordingly. No compatibility settings are provided.
- We have removed the compatibility settings for `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` as their life-cycle has reached its end.
- We have removed the experimental thread schedulers `hierarchy_scheduler`, `periodic_priority_scheduler` and `throttling_scheduler` in an effort to clean up and consolidate our thread schedulers.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #3250<sup>2791</sup> - Apex refactoring with guids
- PR #3249<sup>2792</sup> - Updating People.qbk
- PR #3246<sup>2793</sup> - Assorted fixes for CUDA
- PR #3245<sup>2794</sup> - Apex refactoring with guids
- PR #3242<sup>2795</sup> - Modify task counting in thread\_queue.hpp
- PR #3240<sup>2796</sup> - Fixed typos
- PR #3238<sup>2797</sup> - Readding accidentally removed std::abort
- PR #3237<sup>2798</sup> - Adding Pipeline example
- PR #3236<sup>2799</sup> - Fixing memory\_block
- PR #3233<sup>2800</sup> - Make schedule\_thread take suspended threads into account
- Issue #3226<sup>2801</sup> - memory\_block is breaking, signaling SIGSEGV on a thread on creation and freeing
- PR #3225<sup>2802</sup> - Applying quick fix for hwloc-2.0
- Issue #3224<sup>2803</sup> - HPX counters crashing the application
- PR #3223<sup>2804</sup> - Fix returns when setting config entries
- Issue #3222<sup>2805</sup> - Errors linking libhpx.so
- Issue #3221<sup>2806</sup> - HPX on Mac OS X with HWLoc 2.0.0 fails to run
- PR #3216<sup>2807</sup> - Reorder a variadic array to satisfy VS 2017 15.6
- PR #3214<sup>2808</sup> - Changed prerequisites.qbk to avoid confusion while building boost
- PR #3213<sup>2809</sup> - Relax locks for thread suspension to avoid holding locks when yielding
- PR #3212<sup>2810</sup> - Fix check in sequenced\_executor test
- PR #3211<sup>2811</sup> - Use preinit\_array to set argc/argv in init\_globally example

- PR #2821<sup>3157</sup> - Fix bugs and improve that about HPX\_HAVE\_CXX11\_AUTO\_RETURN\_VALUE of CMake
- PR #2820<sup>3158</sup> - Support C++11 in benchmark codes of parallel::partition and parallel::partition\_copy
- PR #2819<sup>3159</sup> - Fix compile errors in unit test of container version of parallel::partition
- Issue #2818<sup>3160</sup> - A strange thing in parallel::util::detail::handle\_local\_exceptions
- Issue #2815<sup>3161</sup> - HPX fails to compile with HPX\_WITH\_CUDA=ON and the new CUDA 9.0 RC
- Issue #2814<sup>3162</sup> - Using ‘gmakeN’ after ‘cmake’ produces error in src/CMakeFiles/hpx.dir/runtime/agas/addressing\_service.cpp.o
- PR #2813<sup>3163</sup> - Properly support [[noreturn]] attribute if available
- Issue #2812<sup>3164</sup> - Compilation fails with gcc 7.1.1
- PR #2811<sup>3165</sup> - Adding hpx::launch::lazy and support for async, dataflow, and future::then
- PR #2810<sup>3166</sup> - Add option allowing to disable deprecation warning
- PR #2809<sup>3167</sup> - Disable throttling scheduler if HWLOC is not found/used
- PR #2808<sup>3168</sup> - Fix compile errors on some environments of parallel::partition
- Issue #2807<sup>3169</sup> - Difficulty building with HPX\_WITH\_HWLOC=Off
- PR #2806<sup>3170</sup> - Partitioned vector
- PR #2805<sup>3171</sup> - Serializing collections with non-default constructible data
- PR #2802<sup>3172</sup> - Fix FreeBSD 11
- Issue #2801<sup>3173</sup> - Rate limiting techniques in io\_service
- Issue #2800<sup>3174</sup> - New Launch Policy: async\_if
- PR #2799<sup>3175</sup> - Fix a unit test failure on GCC in tuple\_cat
- PR #2798<sup>3176</sup> - bump minimum required cmake to 3.0 in test
- PR #2797<sup>3177</sup> - Making sure future::wait\_for et.al. work properly for action results
- Issue #2796<sup>3178</sup> - wait\_for does always in “deferred” state for calls on remote localities
- Issue #2795<sup>3179</sup> - Serialization of types without default constructor

## 2.10.13 HPX V1.0.0 (Apr 24, 2017)

### General changes

Here are some of the main highlights and changes for this release (in no particular order):

- Added the facility `hpx::split_future` which allows one to convert a `future<tuple<Ts...>>` into a `tuple<future<Ts>...>`. This functionality is not available when compiling *HPX* with VS2012.
- Added a new type of performance counter which allows one to return a list of values for each invocation. We also added a first counter of this type which collects a histogram of the times between parcels being created.
- Added new LCOs: `hpx::lcos::channel` and `hpx::lcos::local::channel` which are very similar to the well known channel constructs used in the Go language.
- Added new performance counters reporting the amount of data handled by the networking layer on a action-by-action basis (please see PR #2289<sup>3400</sup> for more details).
- Added a new facility `hpx::lcos::barrier`, replacing the equally named older one. The new facility has a slightly changed API and is much more efficient. Most notable, the new facility exposes a (global) function `hpx::lcos::barrier::synchronize()` which represents a global barrier across all localities.

<sup>3395</sup> <https://github.com/STELLAR-GROUP/hpx/issues/863>

<sup>3396</sup> <https://github.com/STELLAR-GROUP/hpx/issues/856>

<sup>3397</sup> <https://github.com/STELLAR-GROUP/hpx/issues/726>

<sup>3398</sup> <https://github.com/STELLAR-GROUP/hpx/issues/701>

<sup>3399</sup> <https://github.com/STELLAR-GROUP/hpx/issues/528>

<sup>3400</sup> <https://github.com/STELLAR-GROUP/hpx/pull/2289>

- We have started to add support for vectorization to our parallel algorithm implementations. This support depends on using an external library, currently either Vc Library or [boost\\_simd](#). Please see Issue #2333<sup>3401</sup> for a list of currently supported algorithms. This is an experimental feature and its implementation and/or API might change in the future. Please see this blog-post<sup>3402</sup> for more information.
- The parameter sequence for the `hpx::parallel::transform_reduce` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overload can be still enabled at configure time by specifying `-DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake.
- The algorithm `hpx::parallel::inner_product` has been renamed to `hpx::parallel::transform_reduce` to match the changes this algorithm has undergone while being moved to C++17. The old `inner_product` names can be still enabled at configure time by specifying `-DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake.
- Added versions of `hpx::get_ptr` taking client side representations for component instances as their parameter (instead of a global id).
- Added the helper utility `hpx::performance_counters::performance_counter_set` helping to encapsulate a set of performance counters to be managed concurrently.
- All execution policies and related classes have been renamed to be consistent with the naming changes applied for C++17. All policies now live in the namespace `hpx::parallel::execution`. The old names can be still enabled at configure time by specifying `-DHPX_WITH_EXECUTION_POLICY_COMPATIBILITY=On` to CMake.
- The thread scheduling subsystem has undergone a major refactoring which results in significant performance improvements. We have also improved the performance of creating `hpx::future` and of various facilities handling those.
- We have consolidated all of the code in HPX.Compute related to the integration of CUDA. `hpx::partitioned_vector` has been enabled to be usable with `hpx::compute::vector` which allows one to place the partitions on one or more GPU devices.
- Added new performance counters exposing various internals of the thread scheduling subsystem, such as the current idle- and busy-loop counters and instantaneous scheduler utilization.
- Extended and improved the use of the ITTNotify hooks allowing to collect performance counter data and function annotation information from within the Intel Amplifier tool.

## Breaking changes

- We have dropped support for the gcc compiler versions V4.6 and 4.7. The minimal gcc version we now test on is gcc V4.8.
- We have removed (default) support for `boost::chrono` in interfaces, uses of it have been replaced with `std::chrono`. This facility can be still enabled at configure time by specifying `-DHPX_WITH_BOOST_CHRONO_COMPATIBILITY=On` to CMake.
- The parameter sequence for the `hpx::parallel::transform_reduce` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17.
- The algorithm `hpx::parallel::inner_product` has been renamed to `hpx::parallel::transform_reduce` to match the changes this algorithm has undergone while being moved to C++17.
- the build options `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` are now disabled by default. Please change your code still depending on the deprecated interfaces.

<sup>3401</sup> <https://github.com/STELLAR-GROUP/hpx/issues/2333>

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #2596<sup>3403</sup> - Adding apex data
- PR #2595<sup>3404</sup> - Remove obsolete file
- Issue #2594<sup>3405</sup> - FindOpenCL.cmake mismatch with the official cmake module
- PR #2592<sup>3406</sup> - First attempt to introduce spmd\_block in hpx
- Issue #2591<sup>3407</sup> - Feature request: continuation (then) which does not require the callable object to take a future<R> as parameter
- PR #2588<sup>3408</sup> - Daint fixes
- PR #2587<sup>3409</sup> - Fixing transfer\_(continuation)\_action::schedule
- PR #2585<sup>3410</sup> - Work around MSVC having an ICE when compiling with -Ob2
- PR #2583<sup>3411</sup> - changing 7zip command to 7za in roll\_release.sh
- PR #2582<sup>3412</sup> - First attempt to introduce spmd\_block in hpx
- PR #2581<sup>3413</sup> - Enable annotated function for parallel algorithms
- PR #2580<sup>3414</sup> - First attempt to introduce spmd\_block in hpx
- PR #2579<sup>3415</sup> - Make thread NICE level setting an option
- PR #2578<sup>3416</sup> - Implementing enqueue instead of busy wait when no sender is available
- PR #2577<sup>3417</sup> - Retrieve -std=c++11 consistent nvcc flag

- PR #2407<sup>3562</sup> - Solving #2402 and #2403
- PR #2406<sup>3563</sup> - Improve guards
- PR #2405<sup>3564</sup> - Enable parallel::for\_each for iterators returning proxy types
- PR #2404<sup>3565</sup> - Forward the explicitly given result\_type in the hpx invoke
- Issue #2403<sup>3566</sup> - datapar\_execution + zip iterator: lambda arguments aren't references
- Issue #2402<sup>3567</sup> - datapar algorithm instantiated with wrong type #2402
- PR #2401<sup>3568</sup> - Added support for imported libraries to HPX\_Libraries.cmake
- PR #2400<sup>3569</sup> - Use CMake policy CMP0060
- Issue #2399<sup>3570</sup> - Error trying to push back vector of futures to vector
- PR #2398<sup>3571</sup> - Allow config #defines to be written out to custom config/defines.hpp
- Issue #2397<sup>3572</sup> - CMake generated config defines can cause tedious rebuilds category
- Issue #2396<sup>3573</sup> - BOOST\_ROOT paths are not used at link time
- PR #2395<sup>3574</sup> - Fix target\_link\_libraries() issue when HPX Cuda is enabled
- Issue #2394<sup>3575</sup> - Template compilation error using HPX\_WITH\_DATAPAR\_LIBFLATARRAY
- PR #2393<sup>3576</sup> - Fixing lock registration for recursive mutex
- PR #2392<sup>3577</sup> - Add keywords in target\_link\_libraries in hpx\_setup\_target
- PR #2391<sup>3578</sup> - Clang goroutines
- Issue #2390<sup>3579</sup> - Adapt execution policy name changes from C++17
- PR #2389<sup>3580</sup> - Chunk allocator and pool are not used and are obsolete
- PR #2388<sup>3581</sup> - Adding functionalities to datapar needed by octotiger
- PR #2387<sup>3582</sup> - Fixing race condition for early parcels
- Issue #2386<sup>3583</sup> - Lock registration broken for recursive\_mutex
- PR #2385<sup>3584</sup> - Datapar zip iterator

## 2.10.14 HPX V0.9.99 (Jul 15, 2016)

### General changes

As the version number of this release hints, we consider this release to be a preview for the upcoming *HPX* V1.0. All of the functionalities we set out to implement for V1.0 are in place; all of the features we wanted to have exposed are ready. We are very happy with the stability and performance of *HPX* and we would like to present this release to the community in order for us to gather broad feedback before releasing V1.0. We still expect for some minor details to change, but on the whole this release represents what we would like to have in a V1.0.

Overall, since the last release we have had almost 1600 commits while closing almost 400 tickets. These numbers reflect the incredible development activity we have seen over the last couple of months. We would like to express a big ‘Thank you!’ to all contributors and those who helped to make this release happen.

The most notable addition in terms of new functionality available with this release is the full implementation of object migration (i.e. the ability to transparently move *HPX* components to a different compute node). Additionally, this release of *HPX* cleans up many minor issues and some API inconsistencies.

Here are some of the main highlights and changes for this release (in no particular order):

- We have fixed a couple of issues in AGAS and the parcel layer which have caused hangs, segmentation faults at exit, and a slowdown of applications over time. Fixing those has significantly increased the overall stability and performance of distributed runs.
- We have started to add parallel algorithm overloads based on the C++ Extensions for Ranges (N4560<sup>3726</sup>) proposal. This also includes the addition of projections to the existing algorithms. Please see Issue #1668<sup>3727</sup> for a list of algorithms which have been adapted to N4560<sup>3728</sup>.
- We have implemented index-based parallel for-loops based on a corresponding standardization proposal (P0075R1<sup>3729</sup>). Please see Issue #2016<sup>3730</sup> for a list of available algorithms.
- We have added implementations for more parallel algorithms as proposed for the upcoming C++ 17 Standard. See Issue #1141<sup>3731</sup> for an overview of which algorithms are available by now.
- We have started to implement a new prototypical functionality with *HPX.Compute* which uniformly exposes some of the higher level APIs to heterogeneous architectures (currently CUDA). This functionality is an early preview and should not be considered stable. It may change considerably in the future.
- We have pervasively added (optional) executor arguments to all API functions which schedule new work. Executors are now used throughout the code base as the main means of executing tasks.
- Added `hpx::make_future<R>(future<T> &&)` allowing to convert a future of any type T into a future of any other type R, either based on default conversion rules of the embedded types or using a given explicit conversion function.

<sup>3723</sup> <https://github.com/STELLAR-GROUP/hpx/issues/668>

<sup>3724</sup> <https://github.com/STELLAR-GROUP/hpx/issues/533>

<sup>3725</sup> <https://github.com/STELLAR-GROUP/hpx/issues/475>

<sup>3726</sup> <http://wg21.link/n4560>

<sup>3727</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1668>

<sup>3728</sup> <http://wg21.link/n4560>

<sup>3729</sup> <http://wg21.link/p0075r1>

<sup>3730</sup> <https://github.com/STELLAR-GROUP/hpx/issues/2016>

<sup>3731</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1141>

- We finally finished the implementation of transparent migration of components to another locality. It is now possible to trigger a migration operation without ‘stopping the world’ for the object to migrate. *HPX* will make sure that no work is being performed on an object before it is migrated and that all subsequently scheduled work for the migrated object will be transparently forwarded to the new locality. Please note that the global id of the migrated object does not change, thus the application will not have to be changed in any way to support this new functionality. Please note that this feature is currently considered experimental. See [Issue #559<sup>3732</sup>](#) and [PR #1966<sup>3733</sup>](#) for more details.
- The `hpx::dataflow` facility is now usable with actions. Similarly to `hpx::async`, actions can be specified as an explicit template argument (`hpx::dataflow<Action>(target, ...)`) or as the first argument (`hpx::dataflow(Action(), target, ...)`). We have also enabled the use of distribution policies as the target for dataflow invocations. Please see [Issue #1265<sup>3734</sup>](#) and [PR #1912<sup>3735</sup>](#) for more information.
- Adding overloads of `gather_here` and `gather_there` to accept the plain values of the data to gather (in addition to the existing overloads expecting futures).
- We have cleaned up and refactored large parts of the code base. This helped reducing compile and link times of *HPX* itself and also of applications depending on it. We have further decreased the dependency of *HPX* on the Boost libraries by replacing part of those with facilities available from the standard libraries.
- Wherever possible we have removed dependencies of our API on Boost by replacing those with the equivalent facility from the C++11 standard library.
- We have added new performance counters for parcel coalescing, file-IO, the AGAS cache, and overall scheduler time. Resetting performance counters has been overhauled and fixed.
- We have introduced a generic client type `hpx::components::client<>` and added support for using it with `hpx::async`. This removes the necessity to implement specific client types for every component type without losing type safety. This deemphasizes the need for using the low level `hpx::id_type` for referencing (possibly remote) component instances. The plan is to deprecate the direct use of `hpx::id_type` in user code in the future.
- We have added a special iterator which supports automatic prefetching of one or more arrays for speeding up loop-like code (see `hpx::parallel::util::make_prefetcher_context()`).
- We have extended the interfaces exposed from executors (as proposed by [N4406<sup>3736</sup>](#)) to accept an arbitrary number of arguments.

## Breaking changes

- In order to move the dataflow facility to namespace `hpx` we added a definition of `hpx::dataflow` which might create ambiguities in existing codes. The previous definition of this facility (`hpx::lcos::local::dataflow`) has been deprecated and is available only if the constant `-DHPX_WITH_LOCAL_DATAFLOW_COMPATIBILITY=On` to [CMake<sup>3737</sup>](#) is defined at configuration time. Please explicitly qualify all uses of the dataflow facility if you enable this compatibility setting and encounter ambiguities.
- The adaptation of the C++ Extensions for Ranges ([N4560<sup>3738</sup>](#)) proposal imposes some breaking changes related to the return types of some of the parallel algorithms. Please see [Issue #1668<sup>3739</sup>](#) for a list of algorithms which have already been adapted.
- The facility `hpx::lcos::make_future_void()` has been replaced by `hpx::make_future<void>()`.

<sup>3732</sup> <https://github.com/STELLAR-GROUP/hpx/issues/559>

<sup>3733</sup> <https://github.com/STELLAR-GROUP/hpx/pull/1966>

<sup>3734</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1265>

<sup>3735</sup> <https://github.com/STELLAR-GROUP/hpx/pull/1912>

<sup>3736</sup> <http://wg21.link/n4406>

<sup>3737</sup> <https://www.cmake.org>

<sup>3738</sup> <http://wg21.link/n4560>

<sup>3739</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1668>

- We have removed support for Intel V13 and gcc 4.4.x.
- We have removed (default) support for the generic `hpx::parallel::execution_policy` because it was removed from the Parallelism TS (`__cpp11_n4104__`) while it was being added to the upcoming C++17 Standard. This facility can be still enabled at configure time by specifying `-DHPX_WITH_GENERIC_EXECUTION_POLICY=On` to CMake.
- Uses of `boost::shared_ptr` and related facilities have been replaced with `std::shared_ptr` and friends. Uses of `boost::unique_lock`, `boost::lock_guard` etc. have also been replaced by the equivalent (and equally named) tools available from the C++11 standard library.
- Facilities that used to expect an explicit `boost::unique_lock` now take an `std::unique_lock`. Additionally, `condition_variable` no longer aliases `condition_variable_any`; its interface now only works with `std::unique_lock<local::mutex>`.
- Uses of `boost::function`, `boost::bind`, `boost::tuple` have been replaced by the corresponding facilities in *HPX* (`hpx::util::function`, `hpx::util::bind`, and `hpx::util::tuple`, respectively).

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #2250<sup>3740</sup> - change default chunker of parallel executor to static one
- PR #2247<sup>3741</sup> - HPX on ppc64le
- PR #2244<sup>3742</sup> - Fixing MSVC problems
- PR #2238<sup>3743</sup> - Fixing small typos
- PR #2237<sup>3744</sup> - Fixing small typos
- PR #2234<sup>3745</sup> - Fix broken add test macro when extra args are passed in
- PR #2231<sup>3746</sup> - Fixing possible race during future awaiting in serialization
- PR #2230<sup>3747</sup> - Fix stream nvcc
- PR #2229<sup>3748</sup> - Fixed run\_as\_hpx\_thread
- PR #2228<sup>3749</sup> - On prefetching\_test branch : adding prefetching\_iterator and related tests used for prefetching containers within lambda functions
- PR #2227<sup>3750</sup> - Support for HPXCL's opencl::event
- PR #2226<sup>3751</sup> - Preparing for release of V0.9.99
- PR #2225<sup>3752</sup> - fix issue when compiling components with hpxcxx
- PR #2224<sup>3753</sup> - Compute alloc fix

## 2.10.15 HPX V0.9.11 (Nov 11, 2015)

Our main focus for this release was the design and development of a coherent set of higher-level APIs exposing various types of parallelism to the application programmer. We introduced the concepts of an **executor**, which can be used to customize the **where** and **when** of execution of tasks in the context of parallelizing codes. We extended all APIs related to managing parallel tasks to support executors which gives the user the choice of either using one of the predefined executor types or to provide its own, possibly application specific, executor. We paid very close attention to align all of these changes with the existing C++ Standards documents or with the ongoing proposals for standardization.

This release is the first after our change to a new development policy. We switched all development to be strictly performed on branches only, all direct commits to our main branch (**master**) are prohibited. Any change has to go through a peer review before it will be merged to **master**. As a result the overall stability of our code base has significantly increased, the development process itself has been simplified. This change manifests itself in a large number of pull-requests which have been merged (please see below for a full list of closed issues and pull-requests). All in all for this release, we closed almost 100 issues and merged over 290 pull-requests. There have been over 1600 commits to the **master** branch since the last release.

## General changes

- We are moving into the direction of unifying managed and simple components. As such, the classes `hpx::components::component` and `hpx::components::component_base` have been added which currently just forward to the currently existing simple component facilities. The examples have been converted to only use those two classes.
- Added integration with the CircleCI<sup>4134</sup> hosted continuous integration service. This gives us constant and immediate feedback on the health of our master branch.
- The compiler configuration subsystem in the build system has been reimplemented. Instead of using Boost.Config we now use our own lightweight set of cmake scripts to determine the available language and library features supported by the used compiler.
- The API for creating instances of components has been consolidated. All component instances should be created using the `hpx::new_` only. It allows one to instantiate both, single component instances and multiple component instances. The placement of the created components can be controlled by special distribution policies. Please see the corresponding documentation outlining the use of `hpx::new_`.
- Introduced four new distribution policies which can be used with many API functions which traditionally expected to be used with a locality id. The new distribution policies are:
  - `hpx::components::default_distribution_policy` which tries to place multiple component instances as evenly as possible.
  - `hpx::components::colocating_distribution_policy` which will refer to the locality where a given component instance is currently placed.
  - `hpx::components::binpacking_distribution_policy` which will place multiple component instances as evenly as possible based on any performance counter.
  - `hpx::components::target_distribution_policy` which allows one to represent a given locality in the context of a distribution policy.
- The new distribution policies can now be also used with `hpx::async`. This change also deprecates `hpx::async_colocated(id, ...)` which now is replaced by a distribution policy: `hpx::async(hpx::colocated(id), ...)`.
- The `hpx::vector` and `hpx::unordered_map` data structures can now be used with the new distribution policies as well.
- The parallel facility `hpx::parallel::task_region` has been renamed to `hpx::parallel::task_block` based on the changes in the corresponding standardization proposal N4411<sup>4135</sup>.
- Added extensions to the parallel facility `hpx::parallel::task_block` allowing to combine a `task_block` with an execution policy. This implies a minor breaking change as the `hpx::parallel::task_block` is now a template.
- Added new LCOs: `hpx::lcos::latch` and `hpx::lcos::local::latch` which semantically conform to the proposed `std::latch` (see N4399<sup>4136</sup>).
- Added performance counters exposing data related to data transferred by input/output (filesystem) operations (thanks to Maciej Brodowicz).
- Added performance counters allowing to track the number of action invocations (local and remote invocations).
- Added new command line options `-hpx:print-counter-at` and `-hpx:reset-counters`.

<sup>4134</sup> <https://circleci.com/gh/STELLAR-GROUP/hpx>

<sup>4135</sup> <http://wg21.link/n4411>

<sup>4136</sup> <http://wg21.link/n4399>

- The `hpx::vector` component has been renamed to `hpx::partitioned_vector` to make it explicit that the underlying memory is not contiguous.
- Introduced a completely new and uniform higher-level parallelism API which is based on executors. All existing parallelism APIs have been adapted to this. We have added a large number of different executor types, such as a numa-aware executor, a this-thread executor, etc.
- Added support for the MingW toolchain on Windows (thanks to Eric Lemanissier).
- HPX now includes support for APEX, (Autonomic Performance Environment for eXascale). APEX is an instrumentation and software adaptation library that provides an interface to TAU profiling / tracing as well as runtime adaptation of HPX applications through policy definitions. For more information and documentation, please see <https://github.com/UO-OACISS/xpress-apex>. To enable APEX at configuration time, specify `-DHPX_WITH_APEX=On`. To also include support for TAU profiling, specify `-DHPX_WITH_TAU=On` and specify the `-DTAU_ROOT`, `-DTAU_ARCH` and `-DTAU_OPTIONS` cmake parameters.
- We have implemented many more of the *Using parallel algorithms*. Please see Issue #1141<sup>4137</sup> for the list of all available parallel algorithms (thanks to Daniel Bourgeois and John Biddiscombe for contributing their work).

## Breaking changes

- We are moving into the direction of unifying managed and simple components. In order to stop exposing the old facilities, all examples have been converted to use the new classes. The breaking change in this release is that performance counters are now a `hpx::components::component_base` instead of `hpx::components::managed_component_base`.
- We removed the support for stackless threads. It turned out that there was no performance benefit when using stackless threads. As such, we decided to clean up our codebase. This feature was not documented.
- The CMake project name has changed from ‘hpx’ to ‘HPX’ for consistency and compatibility with naming conventions and other CMake projects. Generated config files go into `<prefix>/lib/cmake/HPX` and not `<prefix>/lib/cmake/hpx`.
- The macro `HPX_REGISTER_MINIMAL_COMPONENT_FACTORY` has been deprecated. Please use `HPX_REGISTER_COMPONENT` instead. The old macro will be removed in the next release.
- The obsolete distributing\_factory and binpacking\_factory components have been removed. The corresponding functionality is now provided by the `hpx::new_` API function in conjunction with the `hpx::default_layout` and `hpx::binpacking` distribution policies (`hpx::components::default_distribution_policy` and `hpx::components::binpacking_distribution_policy`)
- The API function `hpx::new_colocated` has been deprecated. Please use the consolidated API `hpx::new_` in conjunction with the new `hpx::colocated` distribution policy (`hpx::components::colocating_distribution_policy`) instead. The old API function will still be available for at least one release of `HPX` if the configuration variable `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` is enabled.
- The API function `hpx::async_colocated` has been deprecated. Please use the consolidated API `hpx::async` in conjunction with the new `hpx::colocated` distribution policy (`hpx::components::colocating_distribution_policy`) instead. The old API function will still be available for at least one release of `HPX` if the configuration variable `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` is enabled.
- The obsolete remote\_object component has been removed.

---

<sup>4137</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1141>

- Replaced the use of Boost.Serialization with our own solution. While the new version is mostly compatible with Boost.Serialization, this change requires some minor code modifications in user code. For more information, please see the corresponding announcement<sup>4138</sup> on the [hpx-users@stellar.cct.lsu.edu](mailto:hpx-users@stellar.cct.lsu.edu) mailing list.
- The names used by cmake to influence various configuration options have been unified. The new naming scheme relies on all configuration constants to start with `HPX_WITH_...`, while the preprocessor constant which is used at build time starts with `HPX_HAVE_...`. For instance, the former cmake command line `-DHPX_MALLOC=...` now has to be specified a `-DHPX_WITH_MALLOC=...` and will cause the preprocessor constant `HPX_HAVE_MALLOC` to be defined. The actual name of the constant (i.e. `MALLOC`) has not changed. Please see the corresponding documentation for more details ([CMake variables used to configure HPX](#)).
- The `get_gid()` functions exposed by the component base classes `hpx::components::server::simple_component_base`, `hpx::components::server::managed_component_base`, and `hpx::components::server::fixed_component_base` have been replaced by two new functions: `get_unmanaged_id()` and `get_id()`. To enable the old function name for backwards compatibility, use the cmake configuration option `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On`.
- All functions which were named `get_gid()` but were returning `hpx::id_type` have been renamed to `get_id()`. To enable the old function names for backwards compatibility, use the cmake configuration option `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On`.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #1855<sup>4139</sup> - Completely removing external/endian
- PR #1854<sup>4140</sup> - Don't pollute CMAKE\_CXX\_FLAGS through `find_package()`
- PR #1853<sup>4141</sup> - Updating CMake configuration to get correct version of TAU library
- PR #1852<sup>4142</sup> - Fixing Performance Problems with MPI Parcelport
- PR #1851<sup>4143</sup> - Fixing `hpx_add_link_flag()` and `hpx_remove_link_flag()`
- PR #1850<sup>4144</sup> - Fixing 1836, adding `parallel::sort`
- PR #1849<sup>4145</sup> - Fixing configuration for use of more than 64 cores
- PR #1848<sup>4146</sup> - Change default APEX version for release
- PR #1847<sup>4147</sup> - Fix `client_base::then` on release
- PR #1846<sup>4148</sup> - Removing broken `lcos::local::channel` from release
- PR #1845<sup>4149</sup> - Adding example demonstrating a possible safe-object implementation to release
- PR #1844<sup>4150</sup> - Removing stubs from accumulator examples

<sup>4196</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1788>

- Issue #1787<sup>4197</sup> - discover\_counter\_types not working
- PR #1786<sup>4198</sup> - Changing addressing\_service to use std::unordered\_map instead of std::map
- PR #1785<sup>4199</sup> - Fix is\_iterator for container algorithms
- PR #1784<sup>4200</sup> - Adding new command line options:
- PR #1783<sup>4201</sup> - Minor changes for APEX support
- PR #1782<sup>4202</sup> - Drop legacy forwarding action traits
- PR #1781<sup>4203</sup> - Attempt to resolve the race between cv::wait\_xxx and cv::notify\_all
- PR #1780<sup>4204</sup> - Removing serialize\_sequence
- PR #1779<sup>4205</sup> - Fixed #1501: hwloc configuration options are wrong for MIC
- PR #1778<sup>4206</sup> - Removing ability to enable/disable parcel handling
- PR #1777<sup>4207</sup> - Completely removing stackless threads
- PR #1776<sup>4208</sup> - Cleaning up util/plugin
- PR #1775<sup>4209</sup> - Agas fixes
- PR #1774<sup>4210</sup> - Action invocation count
- PR #1773<sup>4211</sup> - replaced MSVC variable with WIN32
- PR #1772<sup>4212</sup> - Fixing Problems in MPI parcelport and future serialization.
- PR #1771<sup>4213</sup> - Fixing intel 13 compiler errors related to variadic template template parameters for lcos::when\_tests
- PR #1770<sup>4214</sup> - Forwarding decay to std::
- PR #1769<sup>4215</sup> - Add more characters with special regex meaning to the existing patch
- PR #1768<sup>4216</sup> - Adding test for receive\_buffer
- PR #1767<sup>4217</sup> - Making sure that uptime counter throws exception on any attempt to be reset
- PR #1766<sup>4218</sup> - Cleaning up code related to throttling scheduler
- PR #1765<sup>4219</sup> - Restricting thread\_data to creating only with intrusive\_pointers

- Issue #1737<sup>4243</sup> - Uptime problems
- PR #1736<sup>4244</sup> - added convenience c-tor and begin()/end() to serialize\_buffer
- PR #1735<sup>4245</sup> - Config includes
- PR #1734<sup>4246</sup> - Fixed #1688: Add timer counters for tfunc\_total and exec\_total
- Issue #1733<sup>4247</sup> - Add unit test for hpx/lcos/local/receive\_buffer.hpp
- PR #1732<sup>4248</sup> - Renaming get\_os\_thread\_count
- PR #1731<sup>4249</sup> - Basename registration
- Issue #1730<sup>4250</sup> - Use after move of thread\_init\_data
- PR #1729<sup>4251</sup> - Rewriting channel based on new gate component
- PR #1728<sup>4252</sup> - Fixing #1722
- PR #1727<sup>4253</sup> - Fixing compile problems with apply\_colocated
- PR #1726<sup>4254</sup> - Apex integration
- PR #1725<sup>4255</sup> - fixed test timeouts
- PR #1724<sup>4256</sup> - Renaming vector
- Issue #1723<sup>4257</sup> - Drop support for intel compilers and gcc 4.4. based standard libs
- Issue #1722<sup>4258</sup> - Add support for detecting non-ready futures before serialization
- PR #1721<sup>4259</sup> - Unifying parallel executors, initializing from launch policy
- PR #1720<sup>4260</sup> - dropped superfluous typedef
- Issue #1718<sup>4261</sup> - Windows 10 x64, VS 2015 - Unknown CMake command “add\_hpx\_pseudo\_target”.
- PR #1717<sup>4262</sup> - Timed executor traits for thread-executors
- PR #1716<sup>4263</sup> - serialization of arrays didn't work with non-pod types. fixed
- PR #1715<sup>4264</sup> - List serialization
- PR #1714<sup>4265</sup> - changing misspellings

## 2.10.16 HPX V0.9.10 (Mar 24, 2015)

### General changes

This is the 12th official release of *HPX*. It coincides with the 7th anniversary of the first commit to our source code repository. Since then, we have seen over 12300 commits amounting to more than 220000 lines of C++ code.

The major focus of this release was to improve the reliability of large scale runs. We believe to have achieved this goal as we now can reliably run *HPX* applications on up to ~24k cores. We have also shown that *HPX* can be used with success for symmetric runs (applications using both, host cores and Intel Xeon/Phi coprocessors). This is a huge step forward in terms of the usability of *HPX*. The main focus of this work involved isolating the causes of the segmentation faults at start up and shut down. Many of these issues were discovered to be the result of the suspension of threads which hold locks.

A very important improvement introduced with this release is the refactoring of the code representing our parcel-port implementation. Parcel- ports can now be implemented by 3rd parties as independent plugins which are dynamically loaded at runtime (static linking of parcel-ports is also supported). This refactoring also includes a massive improvement of the performance of our existing parcel-ports. We were able to significantly reduce the networking latencies and to improve the available networking bandwidth. Please note that in this release we disabled the ibverbs and ipc parcel ports as those have not been ported to the new plugin system yet (see Issue #839<sup>4543</sup>).

Another corner stone of this release is our work towards a complete implementation of \_\_cpp11\_n4104\_\_ (Working Draft, Technical Specification for C++ Extensions for Parallelism). This document defines a set of parallel algorithms to be added to the C++ standard library. We now have implemented about 75% of all specified parallel algorithms (see [link hpx.manual.parallel.parallel\_algorithms Parallel Algorithms] for more details). We also implemented some extensions to \_\_cpp11\_n4104\_\_ allowing to invoke all of the algorithms asynchronously.

This release adds a first implementation of `hpx::vector` which is a distributed data structure closely aligned to the functionality of `std::vector`. The difference is that `hpx::vector` stores the data in partitions where the partitions can be distributed over different localities. We started to work on allowing to use the parallel algorithms with `hpx::vector`. At this point we have implemented only a few of the parallel algorithms to support distributed data structures (like `hpx::vector`) for testing purposes (see Issue #1338<sup>4544</sup> for a documentation of our progress).

### Breaking changes

With this release we put a lot of effort into changing the code base to be more compatible to C++11. These changes have caused the following issues for backward compatibility:

- Move to Variadics- All of the API now uses variadic templates. However, this change required to modify the argument sequence for some of the exiting API functions (`hpx::async_continue`, `hpx::apply_continue`, `hpx::when_each`, `hpx::wait_each`, synchronous invocation of actions).
- Changes to Macros- We also removed the macros `HPX_STD_FUNCTION` and `HPX_STD_TUPLE`. This shouldn't affect any user code as we replaced `HPX_STD_FUNCTION` with `hpx::util::function_nonser` which was the default expansion used for this macro. All *HPX* API functions which expect a `hpx::util::function_nonser` (or a `hpx::util::unique_function_nonser`) can now be transparently called with a compatible `std::function` instead. Similarly, `HPX_STD_TUPLE` was replaced by its default expansion as well: `hpx::util::tuple`.

<sup>4542</sup> <https://github.com/STELLAR-GROUP/hpx/issues/524>

<sup>4543</sup> <https://github.com/STELLAR-GROUP/hpx/issues/839>

<sup>4544</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1338>

- Changes to `hpx::unique_future`- `hpx::unique_future`, which was deprecated in the previous release for `hpx::future` is now completely removed from *HPX*. This completes the transition to a completely standards conforming implementation of `hpx::future`.
- Changes to Supported Compilers. Finally, in order to utilize more C++11 semantics, we have officially dropped support for GCC 4.4 and MSVC 2012. Please see our *Prerequisites* page for more details.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1402<sup>4545</sup> - Internal shared\_future serialization copies
- Issue #1399<sup>4546</sup> - Build takes unusually long time...
- Issue #1398<sup>4547</sup> - Tests using the scan partitioner are broken on at least gcc 4.7 and intel compiler
- Issue #1397<sup>4548</sup> - Completely remove `hpx::unique_future`
- Issue #1396<sup>4549</sup> - Parallel scan algorithms with different initial values
- Issue #1395<sup>4550</sup> - Race Condition - `1d_stencil_8` - SuperMIC
- Issue #1394<sup>4551</sup> - “suspending thread while at least one lock is being held” - `1d_stencil_8` - SuperMIC
- Issue #1393<sup>4552</sup> - SEGFAULT in `1d_stencil_8` on SuperMIC
- Issue #1392<sup>4553</sup> - Fixing #1168
- Issue #1391<sup>4554</sup> - Parallel Algorithms for scan partitioner for small number of elements
- Issue #1387<sup>4555</sup> - Failure with more than 4 localities
- Issue #1386<sup>4556</sup> - Dispatching unhandled exceptions to outer user code
- Issue #1385<sup>4557</sup> - Adding Copy algorithms, fixing `parallel::copy_if`
- Issue #1384<sup>4558</sup> - Fixing 1325
- Issue #1383<sup>4559</sup> - Fixed #504: Refactor Dataflow LCO to work with futures, this removes the dataflow component as it is obsolete
- Issue #1382<sup>4560</sup> - `is_sorted`, `is_sorted_until` and `is_partitioned` algorithms
- Issue #1381<sup>4561</sup> - fix for CMake versions prior to 3.1
- Issue #1380<sup>4562</sup> - resolved warning in CMake 3.1 and newer

- Issue #1327<sup>4614</sup> - Typos in docs
- Issue #1326<sup>4615</sup> - Documentation and code diverged in Fibonacci tutorial
- Issue #1325<sup>4616</sup> - Exceptions thrown during parcel handling are not handled correctly
- Issue #1324<sup>4617</sup> - fixed bandwidth calculation
- Issue #1323<sup>4618</sup> - mmap() failed to allocate thread stack due to insufficient resources
- Issue #1322<sup>4619</sup> - HPX fails to build aa182cf
- Issue #1321<sup>4620</sup> - Limiting size of outgoing messages while coalescing parcels
- Issue #1320<sup>4621</sup> - passing a future with launch::deferred in remote function call causes hang
- Issue #1319<sup>4622</sup> - An exception when tries to specify number high priority threads with abp-priority
- Issue #1318<sup>4623</sup> - Unable to run program with abp-priority and numa-sensitivity enabled
- Issue #1317<sup>4624</sup> - N4071 Search/Search\_n finished, minor changes
- Issue #1316<sup>4625</sup> - Add config option to make -Ihpx.run\_hpx\_main!=1 the default
- Issue #1314<sup>4626</sup> - Variadic support for async and apply
- Issue #1313<sup>4627</sup> - Adjust when\_any/some to the latest proposed interfaces
- Issue #1312<sup>4628</sup> - Fixing #857: hpx::naming::locality leaks parcelport specific information into the public interface
- Issue #1311<sup>4629</sup> - Distributed get'er/set'er\_values for distributed vector
- Issue #1310<sup>4630</sup> - Crashing in hpx::parcelset::policies::mpi::connection\_handler::handle\_messages() on Super-MIC

- Issue #196<sup>4657</sup> - Don't store copies of the locality network metadata in the gva table

## 2.10.17 HPX V0.9.9 (Oct 31, 2014, codename Spooky)

### General changes

We have had over 1500 commits since the last release and we have closed over 200 tickets (bugs, feature requests, pull requests, etc.). These are by far the largest numbers of commits and resolved issues for any of the *HPX* releases so far. We are especially happy about the large number of people who contributed for the first time to *HPX*.

- We completed the transition from the older (non-conforming) implementation of `hpx::future` to the new and fully conforming version by removing the old code and by renaming the type `hpx::unique_future` to `hpx::future`. In order to maintain backwards compatibility with existing code which uses the type `hpx::unique_future` we support the configuration variable `HPX_UNIQUE_FUTURE_ALIAS`. If this variable is set to ON while running cmake it will additionally define a template alias for this type.
- We rewrote and significantly changed our build system. Please have a look at the new (now generated) documentation here: [Building HPX](#). Please revisit your build scripts to adapt to the changes. The most notable changes are:
  - `HPX_NO_INSTALL` is no longer necessary.
  - For external builds, you need to set `HPX_DIR` instead of `HPX_ROOT` as described here: [Using HPX with CMake-based projects](#).
  - IDEs that support multiple configurations (Visual Studio and XCode) can now be used as intended. that means no build dir.
  - Building HPX statically (without dynamic libraries) is now supported (`-DHPX_STATIC_LINKING=On`).
  - Please note that many variables used to configure the build process have been renamed to unify the naming conventions (see the section [CMake variables used to configure HPX](#) for more information).
  - This also fixes a long list of issues, for more information see Issue #1204<sup>4658</sup>.
- We started to implement various proposals to the C++ Standardization committee related to parallelism and concurrency, most notably N4409<sup>4659</sup> (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411<sup>4660</sup> (Task Region Rev. 3), and N4313<sup>4661</sup> (Working Draft, Technical Specification for C++ Extensions for Concurrency).
- We completely remodeled our automatic build system to run builds and unit tests on various systems and compilers. This allows us to find most bugs right as they were introduced and helps to maintain a high level of quality and compatibility. The newest build logs can be found at [HPX Buildbot Website](#)<sup>4662</sup>.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1296<sup>4663</sup> - Rename make\_error\_future to make\_exceptional\_future, adjust to N4123
- Issue #1295<sup>4664</sup> - building issue
- Issue #1293<sup>4665</sup> - Transpose example
- Issue #1292<sup>4666</sup> - Wrong abs() function used in example
- Issue #1291<sup>4667</sup> - non-synchronized shift operators have been removed
- Issue #1290<sup>4668</sup> - RDTSCP is defined as true for Xeon Phi build
- Issue #1289<sup>4669</sup> - Fixing 1288
- Issue #1288<sup>4670</sup> - Add new performance counters
- Issue #1287<sup>4671</sup> - Hierarchy scheduler broken performance counters
- Issue #1286<sup>4672</sup> - Algorithm cleanup
- Issue #1285<sup>4673</sup> - Broken Links in Documentation
- Issue #1284<sup>4674</sup> - Uninitialized copy
- Issue #1283<sup>4675</sup> - missing boost::scoped\_ptr includes
- Issue #1282<sup>4676</sup> - Update documentation of build options for schedulers
- Issue #1281<sup>4677</sup> - reset idle rate counter
- Issue #1280<sup>4678</sup> - Bug when executing on Intel MIC
- Issue #1279<sup>4679</sup> - Add improved when\_all/wait\_all
- Issue #1278<sup>4680</sup> - Implement improved when\_all/wait\_all
- Issue #1277<sup>4681</sup> - feature request: get access to argc argv and variables\_map
- Issue #1276<sup>4682</sup> - Remove merging map
- Issue #1274<sup>4683</sup> - Weird (wrong) string code in papi.cpp

- Issue #1273<sup>4684</sup> - Sequential task execution policy
- Issue #1272<sup>4685</sup> - Avoid CMake name clash for Boost.Thread library
- Issue #1271<sup>4686</sup> - Updates on HPX Test Units
- Issue #1270<sup>4687</sup> - hpx/util/safe\_lexical\_cast.hpp is added
- Issue #1269<sup>4688</sup> - Added default value for “LIB” cmake variable
- Issue #1268<sup>4689</sup> - Memory Counters not working
- Issue #1266<sup>4690</sup> - FindHPX.cmake is not installed
- Issue #1263<sup>4691</sup> - apply\_remote test takes too long
- Issue #1262<sup>4692</sup> - Chrono cleanup
- Issue #1261<sup>4693</sup> - Need make install for papi counters and this builds all the examples
- Issue #1260<sup>4694</sup> - Documentation of Stencil example claims
- Issue #1259<sup>4695</sup> - Avoid double-linking Boost on Windows
- Issue #1257<sup>4696</sup> - Adding additional parameter to create\_thread
- Issue #1256<sup>4697</sup> - added buildbot changes to release notes
- Issue #1255<sup>4698</sup> - Cannot build MiniGhost
- Issue #1253<sup>4699</sup> - hpx::thread defects
- Issue #1252<sup>4700</sup> - HPX\_PREFIX is too fragile
- Issue #1250<sup>4701</sup> - switch\_to\_fiber\_emulation does not work properly
- Issue #1249<sup>4702</sup> - Documentation is generated under Release folder
- Issue #1248<sup>4703</sup> - Fix usage of hpx\_generic\_coroutine\_context and get tests passing on powerpc
- Issue #1247<sup>4704</sup> - Dynamic linking error
- Issue #1246<sup>4705</sup> - Make cpuid.cpp C++11 compliant
- Issue #1245<sup>4706</sup> - HPX fails on startup (setting thread affinity mask)

- Issue #1244<sup>4707</sup> - HPX\_WITH\_RDTSC configure test fails, but should succeed
- Issue #1243<sup>4708</sup> - CTest dashboard info for CSCS CDash drop location
- Issue #1242<sup>4709</sup> - Mac fixes
- Issue #1241<sup>4710</sup> - Failure in Distributed with Boost 1.56
- Issue #1240<sup>4711</sup> - fix a race condition in examples.diskperf
- Issue #1239<sup>4712</sup> - fix wait\_each in examples.diskperf
- Issue #1238<sup>4713</sup> - Fixed #1237: hpx::util::portable\_binary\_iarchive failed
- Issue #1237<sup>4714</sup> - hpx::util::portable\_binary\_iarchive faileds
- Issue #1235<sup>4715</sup> - Fixing clang warnings and errors
- Issue #1234<sup>4716</sup> - TCP runs fail: Transport endpoint is not connected
- Issue #1233<sup>4717</sup> - Making sure the correct number of threads is registered with AGAS
- Issue #1232<sup>4718</sup> - Fixing race in wait\_xxx
- Issue #1231<sup>4719</sup> - Parallel minmax
- Issue #1230<sup>4720</sup> - Distributed run of 1d\_stencil\_8 uses less threads than spec. & sometimes gives errors
- Issue #1229<sup>4721</sup> - Unstable number of threads
- Issue #1228<sup>4722</sup> - HPX link error (cmake / MPI)
- Issue #1226<sup>4723</sup> - Warning about struct/class thread\_counters
- Issue #1225<sup>4724</sup> - Adding parallel::replace etc
- Issue #1224<sup>4725</sup> - Extending dataflow to pass through non-future arguments
- Issue #1223<sup>4726</sup> - Remaining find algorithms implemented, N4071
- Issue #1222<sup>4727</sup> - Merging all the changes
- Issue #1221<sup>4728</sup> - No error output when using mpirun with hpx
- Issue #1219<sup>4729</sup> - Adding new AGAS cache performance counters

- Issue #1216<sup>4730</sup> - Fixing using futures (clients) as arguments to actions
- Issue #1215<sup>4731</sup> - Error compiling simple component
- Issue #1214<sup>4732</sup> - Stencil docs
- Issue #1213<sup>4733</sup> - Using more than a few dozen MPI processes on SuperMike results in a seg fault before getting to hpx\_main
- Issue #1212<sup>4734</sup> - Parallel rotate
- Issue #1211<sup>4735</sup> - Direct actions cause the future's shared\_state to be leaked
- Issue #1210<sup>4736</sup> - Refactored local::promise to be standard conformant
- Issue #1209<sup>4737</sup> - Improve command line handling
- Issue #1208<sup>4738</sup> - Adding parallel::reverse and parallel::reverse\_copy
- Issue #1207<sup>4739</sup> - Add copy\_backward and move\_backward
- Issue #1206<sup>4740</sup> - N4071 additional algorithms implemented
- Issue #1204<sup>4741</sup> - Cmake simplification and various other minor changes
- Issue #1203<sup>4742</sup> - Implementing new launch policy for (local) async: hpx::launch::fork.
- Issue #1202<sup>4743</sup> - Failed assertion in connection\_cache.hpp
- Issue #1201<sup>4744</sup> - pkg-config doesn't add mpi link directories
- Issue #1200<sup>4745</sup> - Error when querying time performance counters
- Issue #1199<sup>4746</sup> - library path is now configurable (again)
- Issue #1198<sup>4747</sup> - Error when querying performance counters
- Issue #1197<sup>4748</sup> - tests fail with intel compiler
- Issue #1196<sup>4749</sup> - Silence several warnings
- Issue #1195<sup>4750</sup> - Rephrase initializers to work with VC++ 2012
- Issue #1194<sup>4751</sup> - Simplify parallel algorithms
- Issue #1193<sup>4752</sup> - Adding parallel::equal

- Issue #1192<sup>4753</sup> - HPX(out\_of\_memory) on including <hpx/hpx.hpp>
- Issue #1191<sup>4754</sup> - Fixing #1189
- Issue #1190<sup>4755</sup> - Chrono cleanup
- Issue #1189<sup>4756</sup> - Deadlock .. somewhere? (probably serialization)
- Issue #1188<sup>4757</sup> - Removed `future::get_status()`
- Issue #1186<sup>4758</sup> - Fixed FindOpenCL to find current AMD APP SDK
- Issue #1184<sup>4759</sup> - Tweaking future unwrapping
- Issue #1183<sup>4760</sup> - Extended `parallel::reduce`
- Issue #1182<sup>4761</sup> - `future::unwrap` hangs for `launch::deferred`
- Issue #1181<sup>4762</sup> - Adding `all_of`, `any_of`, and `none_of` and corresponding documentation
- Issue #1180<sup>4763</sup> - `hpx::cout` defect
- Issue #1179<sup>4764</sup> - `hpx::async` does not work for member function pointers when called on types with self-defined unary `operator*`
- Issue #1178<sup>4765</sup> - Implemented variadic `hpx::util::zip_iterator`
- Issue #1177<sup>4766</sup> - MPI parcelport defect
- Issue #1176<sup>4767</sup> - `HPX_DEFINE_COMPONENT_CONST_ACTION_TPL` does not have a 2-argument version
- Issue #1175<sup>4768</sup> - Create `util::zip_iterator` working with `util::tuple<>`
- Issue #1174<sup>4769</sup> - Error Building HPX on linux, `root_certificate_authority.cpp`
- Issue #1173<sup>4770</sup> - `hpx::cout` output lost
- Issue #1172<sup>4771</sup> - HPX build error with Clang 3.4.2
- Issue #1171<sup>4772</sup> - `CMAKE_INSTALL_PREFIX` ignored
- Issue #1170<sup>4773</sup> - Close `hpx_benchmarks` repository on Github
- Issue #1169<sup>4774</sup> - Buildbot emails have syntax error in url
- Issue #1167<sup>4775</sup> - Merge partial implementation of standards proposal N3960

- Issue #1142<sup>4799</sup> - Cannot build HPX with gcc 4.6 on OS X
- Issue #1140<sup>4800</sup> - Fix OpenMP lookup, enable usage of config tests in external CMake projects.
- Issue #1139<sup>4801</sup> - hpx/hpx/config/compiler\_specific.hpp
- Issue #1138<sup>4802</sup> - clean up pkg-config files
- Issue #1137<sup>4803</sup> - Improvements to create binary packages
- Issue #1136<sup>4804</sup> - HPX\_GCC\_VERSION not defined on all compilers
- Issue #1135<sup>4805</sup> - Avoiding collision between winsock2.h and windows.h
- Issue #1134<sup>4806</sup> - Making sure, that hpx::finalize can be called from any locality
- Issue #1133<sup>4807</sup> - 1d stencil examples
- Issue #1131<sup>4808</sup> - Refactor unique\_function implementation
- Issue #1130<sup>4809</sup> - Unique function
- Issue #1129<sup>4810</sup> - Some fixes to the Build system on OS X
- Issue #1128<sup>4811</sup> - Action future args
- Issue #1127<sup>4812</sup> - Executor causes segmentation fault
- Issue #1124<sup>4813</sup> - Adding new API functions: register\_id\_with\_basename, unregister\_id\_with\_basename, find\_ids\_from\_basename; adding test
- Issue #1123<sup>4814</sup> - Reduce nesting of try-catch construct in encode\_parcels?
- Issue #1122<sup>4815</sup> - Client base fixes
- Issue #1121<sup>4816</sup> - Update hpxrun.py.in
- Issue #1120<sup>4817</sup> - HTTS2 tests compile errors on v110 (VS2012)
- Issue #1119<sup>4818</sup> - Remove references to boost::atomic in accumulator example
- Issue #1118<sup>4819</sup> - Only build test thread\_pool\_executor\_1114\_test if HPX\_SCHEDULER is set
- Issue #1117<sup>4820</sup> - local\_queue\_executor linker error on vc110
- Issue #1116<sup>4821</sup> - Disabled performance counter should give runtime errors, not invalid data

## 2.10.18 HPX V0.9.8 (Mar 24, 2014)

We have had over 800 commits since the last release and we have closed over 65 tickets (bugs, feature requests, etc.).

With the changes below, *HPX* is once again leading the charge of a whole new era of computation. By intrinsically breaking down and synchronizing the work to be done, *HPX* insures that application developers will no longer have to fret about where a segment of code executes. That allows coders to focus their time and energy to understanding the data dependencies of their algorithms and thereby the core obstacles to an efficient code. Here are some of the advantages of using *HPX*:

- *HPX* is solidly rooted in a sophisticated theoretical execution model – ParalleX
- *HPX* exposes an API fully conforming to the C++11 and the draft C++14 standards, extended and applied to distributed computing. Everything programmers know about the concurrency primitives of the standard C++ library is still valid in the context of *HPX*.
- It provides a competitive, high performance implementation of modern, future-proof ideas which gives an smooth migration path from today's mainstream techniques
- There is no need for the programmer to worry about lower level parallelization paradigms like threads or message passing; no need to understand pthreads, MPI, OpenMP, or Windows threads, etc.
- There is no need to think about different types of parallelism such as tasks, pipelines, or fork-join, task or data parallelism.
- The same source of your program compiles and runs on Linux, BlueGene/Q, Mac OS X, Windows, and Android.
- The same code runs on shared memory multi-core systems and supercomputers, on handheld devices and Intel® Xeon Phi™ accelerators, or a heterogeneous mix of those.

### General changes

- A major API breaking change for this release was introduced by implementing `hpx::future` and `hpx::shared_future` fully in conformance with the C++11 Standard<sup>4887</sup>. While `hpx::shared_future` is new and will not create any compatibility problems, we revised the interface and implementation of the existing `hpx::future`. For more details please see the mailing list archive<sup>4888</sup>. To avoid any incompatibilities for existing code we named the type which implements the `std::future` interface as `hpx::unique_future`. For the next release this will be renamed to `hpx::future`, making it full conforming to C++11 Standard<sup>4889</sup>.
- A large part of the code base of *HPX* has been refactored and partially re-implemented. The main changes were related to
  - The threading subsystem: these changes significantly reduce the amount of overheads caused by the schedulers, improve the modularity of the code base, and extend the variety of available scheduling algorithms.
  - The parcel subsystem: these changes improve the performance of the *HPX* networking layer, modularize the structure of the parcelports, and simplify the creation of new parcelports for other underlying networking libraries.
  - The API subsystem: these changes improved the conformance of the API to C++11 Standard, extend and unify the available API functionality, and decrease the overheads created by various elements of the API.
  - The robustness of the component loading subsystem has been improved significantly, allowing to more portably and more reliably register the components needed by an application as startup. This additionally speeds up general application initialization.

<sup>4887</sup> <http://www.open-std.org/jtc1/sc22/wg21>

<sup>4888</sup> <http://mail.cct.lsu.edu/pipermail/hpx-users/2014-January/000141.html>

<sup>4889</sup> <http://www.open-std.org/jtc1/sc22/wg21>

- We added new API functionality like `hpx::migrate` and `hpx::copy_component` which are the basic building blocks necessary for implementing higher level abstractions for system-wide load balancing, runtime-adaptive resource management, and object-oriented checkpointing and state-management.
- We removed the use of C++11 move emulation (using Boost.Move), replacing it with C++11 rvalue references. This is the first step towards using more and more native C++11 facilities which we plan to introduce in the future.
- We improved the reference counting scheme used by *HPX* which helps managing distributed objects and memory. This improves the overall stability of *HPX* and further simplifies writing real world applications.
- The minimal Boost version required to use *HPX* is now V1.49.0.
- This release coincides with the first release of HPXPI (V0.1.0), the first implementation of the XPI specification<sup>4890</sup>.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1086<sup>4891</sup> - Expose internal boost::shared\_array to allow user management of array lifetime
- Issue #1083<sup>4892</sup> - Make shell examples copyable in docs
- Issue #1080<sup>4893</sup> - /threads{locality#\*/total}/count/cumulative broken
- Issue #1079<sup>4894</sup> - Build problems on OS X
- Issue #1078<sup>4895</sup> - Improve robustness of component loading
- Issue #1077<sup>4896</sup> - Fix a missing enum definition for ‘take’ mode
- Issue #1076<sup>4897</sup> - Merge Jb master
- Issue #1075<sup>4898</sup> - Unknown CMake command “add\_hpx\_pseudo\_target”
- Issue #1074<sup>4899</sup> - Implement `apply_continue_callback` and `apply_colocated_callback`
- Issue #1073<sup>4900</sup> - The new `apply_colocated` and `async_colocated` functions lead to automatic registered functions
- Issue #1071<sup>4901</sup> - Remove deferred\_packaged\_task
- Issue #1069<sup>4902</sup> - `serialize_buffer` with allocator fails at destruction
- Issue #1068<sup>4903</sup> - Coroutine include and forward declarations missing
- Issue #1067<sup>4904</sup> - Add allocator support to `util::serialize_buffer`

<sup>4903</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1068>

<sup>4904</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1067>

- Issue #1066<sup>4905</sup> - Allow for MPI\_Init being called before HPX launches
- Issue #1065<sup>4906</sup> - AGAS cache isn't used/populated on worker localities
- Issue #1064<sup>4907</sup> - Reorder includes to ensure ws2 includes early
- Issue #1063<sup>4908</sup> - Add hpx::runtime::suspend and hpx::runtime::resume
- Issue #1062<sup>4909</sup> - Fix async\_continue to properly handle return types
- Issue #1061<sup>4910</sup> - Implement async\_colocated and apply\_colocated
- Issue #1060<sup>4911</sup> - Implement minimal component migration
- Issue #1058<sup>4912</sup> - Remove HPX\_UTIL\_TUPLE from code base
- Issue #1057<sup>4913</sup> - Add performance counters for threading subsystem
- Issue #1055<sup>4914</sup> - Thread allocation uses two memory pools
- Issue #1053<sup>4915</sup> - Work stealing flawed
- Issue #1052<sup>4916</sup> - Fix a number of warnings
- Issue #1049<sup>4917</sup> - Fixes for TLS on OSX and more reliable test running
- Issue #1048<sup>4918</sup> - Fixing after 588 hang
- Issue #1047<sup>4919</sup> - Use port '0' for networking when using one locality
- Issue #1046<sup>4920</sup> - composable\_guard test is broken when having more than one thread
- Issue #1045<sup>4921</sup> - Security missing headers
- Issue #1044<sup>4922</sup> - Native TLS on FreeBSD via \_\_thread
- Issue #1043<sup>4923</sup> - async et.al. compute the wrong result type
- Issue #1042<sup>4924</sup> - async et.al. implicitly unwrap reference\_wrappers
- Issue #1041<sup>4925</sup> - Remove redundant costly Kleene stars from regex searches
- Issue #1040<sup>4926</sup> - CMake script regex match patterns has unnecessary kleenes
- Issue #1039<sup>4927</sup> - Remove use of Boost.Move and replace with std::move and real rvalue refs

- Issue #1011<sup>4953</sup> - After installation, running applications from the build/staging directory no longer works
- Issue #1010<sup>4954</sup> - Mergeable decrement requests are not being merged
- Issue #1009<sup>4955</sup> - --hpx:list-symbolic-names crashes
- Issue #1007<sup>4956</sup> - Components are not properly destroyed
- Issue #1006<sup>4957</sup> - Segfault/hang in set\_data
- Issue #1003<sup>4958</sup> - Performance counter naming issue
- Issue #982<sup>4959</sup> - Race condition during startup
- Issue #912<sup>4960</sup> - OS X: component type not found in map
- Issue #663<sup>4961</sup> - Create a buildbot slave based on Clang 3.2/OSX
- Issue #636<sup>4962</sup> - Expose `this_locality::apply<act>(p1, p2);` for local execution
- Issue #197<sup>4963</sup> - Add --console=address option for PBS runs
- Issue #175<sup>4964</sup> - Asynchronous AGAS API

## 2.10.19 HPX V0.9.7 (Nov 13, 2013)

We have had over 1000 commits since the last release and we have closed over 180 tickets (bugs, feature requests, etc.).

### General changes

- Ported HPX to BlueGene/Q
- Improved HPX support for Xeon/Phi accelerators
- Reimplemented `hpx::bind`, `hpx::tuple`, and `hpx::function` for better performance and better compliance with the C++11 Standard. Added `hpx::mem_fn`.
- Reworked `hpx::when_all` and `hpx::when_any` for better compliance with the ongoing C++ standardization effort, added heterogeneous version for those functions. Added `hpx::when_any_swapped`.
- Added `hpx::copy` as a precursor for a migrate functionality
- Added `hpx::get_ptr` allowing to directly access the memory underlying a given component
- Added the `hpx::lcos::broadcast`, `hpx::lcos::reduce`, and `hpx::lcos::fold` collective operations

<sup>4951</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1013>

<sup>4952</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1012>

<sup>4953</sup> <https://github.com/STELLAR-GROUP/hpx/issues/1011>

<sup>4959</sup> <https://github.com/STELLAR-GROUP/hpx/issues/982>

<sup>4960</sup> <https://github.com/STELLAR-GROUP/hpx/issues/912>

<sup>4961</sup> <https://github.com/STELLAR-GROUP/hpx/issues/663>

<sup>4962</sup> <https://github.com/STELLAR-GROUP/hpx/issues/636>

<sup>4963</sup> <https://github.com/STELLAR-GROUP/hpx/issues/197>

<sup>4964</sup> <https://github.com/STELLAR-GROUP/hpx/issues/175>

- Added `hpx::get_locality_name` allowing to retrieve the name of any of the localities for the application.
- Added support for more flexible thread affinity control from the HPX command line, such as new modes for `--hpx:bind` (`balanced`, `scattered`, `compact`), improved default settings when running multiple localities on the same node.
- Added experimental executors for simpler thread pooling and scheduling. This API may change in the future as it will stay aligned with the ongoing C++ standardization efforts.
- Massively improved the performance of the HPX serialization code. Added partial support for zero copy serialization of array and bitwise-copyable types.
- General performance improvements of the code related to threads and futures.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1005<sup>4965</sup> - Allow one to disable array optimizations and zero copy optimizations for each parcelport
- Issue #1004<sup>4966</sup> - Generate new HPX logo image for the docs
- Issue #1002<sup>4967</sup> - If MPI parcelport is not available, running HPX under mpirun should fail
- Issue #1001<sup>4968</sup> - Zero copy serialization raises assert
- Issue #1000<sup>4969</sup> - Can't connect to a HPX application running with the MPI parcelport from a non MPI parcelport locality
- Issue #999<sup>4970</sup> - Optimize `hpx::when_n`
- Issue #998<sup>4971</sup> - Fixed const-correctness
- Issue #997<sup>4972</sup> - Making `serialize_buffer::data()` type save
- Issue #996<sup>4973</sup> - Memory leak in `hpx::lcos::promise`
- Issue #995<sup>4974</sup> - Race while registering pre-shutdown functions
- Issue #994<sup>4975</sup> - `thread_rescheduling` regression test does not compile
- Issue #992<sup>4976</sup> - Correct comments and messages
- Issue #991<sup>4977</sup> - `setcap cap_sys_rawio=ep` for power profiling causes an HPX application to abort
- Issue #989<sup>4978</sup> - Jacobi hangs during execution
- Issue #988<sup>4979</sup> - `multiple_init` test is failing
- Issue #986<sup>4980</sup> - Can't call a function called "init" from "main" when using `<hpx/hpx_main.hpp>`

- Issue #955<sup>5004</sup> --hpx:nodes and --hpx:nodenames do not work with foreign nodes
- Issue #954<sup>5005</sup> - Make order of arguments for hpx::async and hpx::broadcast consistent
- Issue #953<sup>5006</sup> - Cannot use MKL with HPX
- Issue #952<sup>5007</sup> - register\_[pre\_]shutdown\_function never throw
- Issue #951<sup>5008</sup> - Assert when number of threads is greater than hardware concurrency
- Issue #948<sup>5009</sup> - HPX\_HAVE\_GENERIC\_CONTEXT\_COROUTINES conflicts with HPX\_HAVE\_FIBER\_BASED\_COROUTINES
- Issue #947<sup>5010</sup> - Need MPI\_THREAD\_MULTIPLE for backward compatibility
- Issue #946<sup>5011</sup> - HPX does not call MPI\_Finalize
- Issue #945<sup>5012</sup> - Segfault with hpx::lcos::broadcast
- Issue #944<sup>5013</sup> - OS X: assertion pu\_offset\_ < hardware\_concurrency failed
- Issue #943<sup>5014</sup> - #include <hpx/hpx\_main.hpp> does not work
- Issue #942<sup>5015</sup> - Make the BG/Q work with -O3
- Issue #940<sup>5016</sup> - Use separator when concatenating locality name
- Issue #939<sup>5017</sup> - Refactor MPI parcelport to use MPI\_Wait instead of multiple MPI\_Test calls
- Issue #938<sup>5018</sup> - Want to officially access client\_base::gid\_
- Issue #937<sup>5019</sup> - client\_base::gid\_ should be private``
- Issue #936<sup>5020</sup> - Want doxygen-like source code index
- Issue #935<sup>5021</sup> - Build error with gcc 4.6 and Boost 1.54.0 on hpx trunk and 0.9.6
- Issue #933<sup>5022</sup> - Cannot build HPX with Boost 1.54.0
- Issue #932<sup>5023</sup> - Components are destructed too early
- Issue #931<sup>5024</sup> - Make HPX work on BG/Q
- Issue #930<sup>5025</sup> - make git-docs is broken
- Issue #929<sup>5026</sup> - Generating index in docs broken

- Issue #316<sup>5148</sup> - Add message size limitation
- Issue #249<sup>5149</sup> - Clean up locking code in big boot barrier
- Issue #136<sup>5150</sup> - Persistent CMake variables need to be marked as cache variables

## 2.10.20 HPX V0.9.6 (Jul 30, 2013)

We have had over 1200 commits since the last release and we have closed roughly 140 tickets (bugs, feature requests, etc.).

### General changes

The major new features in this release are:

- We further consolidated the API exposed by *HPX*. We aligned our APIs as much as possible with the existing C++11 Standard<sup>5151</sup> and related proposals to the C++ standardization committee (such as N3632<sup>5152</sup> and N3857<sup>5153</sup>).
- We implemented a first version of a distributed AGAS service which essentially eliminates all explicit AGAS network traffic.
- We created a native ibverbs parcelport allowing to take advantage of the superior latency and bandwidth characteristics of Infiniband networks.
- We successfully ported *HPX* to the Xeon Phi platform.
- Support for the SLURM scheduling system was implemented.
- Major efforts have been dedicated to improving the performance counter framework, numerous new counters were implemented and new APIs were added.
- We added a modular parcel compression system allowing to improve bandwidth utilization (by reducing the overall size of the transferred data).
- We added a modular parcel coalescing system allowing to combine several parcels into larger messages. This reduces latencies introduced by the communication layer.

<sup>5152</sup> <http://wg21.link/n3632>

<sup>5153</sup> <http://wg21.link/n3857>

- Added an experimental executors API allowing to use different scheduling policies for different parts of the code. This API has been modelled after the Standards proposal [N3562<sup>5154</sup>](#). This API is bound to change in the future, though.
- Added minimal security support for localities which is enforced on the parcelport level. This support is preliminary and experimental and might change in the future.
- We created a parcelport using low level MPI functions. This is in support of legacy applications which are to be gradually ported and to support platforms where MPI is the only available portable networking layer.
- We added a preliminary and experimental implementation of a tuple-space object which exposes an interface similar to such systems described in the literature (see for instance [The Linda Coordination Language<sup>5155</sup>](#)).

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release. This is again a very long list of newly implemented features and fixed issues.

- Issue #806<sup>5156</sup> - make (all) in examples folder does nothing
- Issue #805<sup>5157</sup> - Adding the introduction and fixing DOCBOOK dependencies for Windows use
- Issue #804<sup>5158</sup> - Add stackless (non-suspendable) thread type
- Issue #803<sup>5159</sup> - Create proper serialization support functions for util::tuple
- Issue #800<sup>5160</sup> - Add possibility to disable array optimizations during serialization
- Issue #798<sup>5161</sup> - HPX\_LIMIT does not work for local dataflow
- Issue #797<sup>5162</sup> - Create a parcelport which uses MPI
- Issue #796<sup>5163</sup> - Problem with Large Numbers of Threads
- Issue #793<sup>5164</sup> - Changing dataflow test case to hang consistently
- Issue #792<sup>5165</sup> - CMake Error
- Issue #791<sup>5166</sup> - Problems with local::dataflow
- Issue #790<sup>5167</sup> - wait\_for() doesn't compile
- Issue #789<sup>5168</sup> - HPX with Intel compiler segfaults
- Issue #788<sup>5169</sup> - Intel compiler support
- Issue #787<sup>5170</sup> - Fixed SFINAEd specializations

<sup>5170</sup> <https://github.com/STELLAR-GROUP/hpx/issues/787>

- Issue #786<sup>5171</sup> - Memory issues during benchmarking.
- Issue #785<sup>5172</sup> - Create an API allowing to register external threads with HPX
- Issue #784<sup>5173</sup> - util::plugin is throwing an error when a symbol is not found
- Issue #783<sup>5174</sup> - How does hpx:bind work?
- Issue #782<sup>5175</sup> - Added quotes around STRING REPLACE potentially empty arguments
- Issue #781<sup>5176</sup> - Make sure no exceptions propagate into the thread manager
- Issue #780<sup>5177</sup> - Allow arithmetics performance counters to expand its parameters
- Issue #779<sup>5178</sup> - Test case for 778
- Issue #778<sup>5179</sup> - Swapping futures segfaults
- Issue #777<sup>5180</sup> - hpx::lcos::details::when\_xxx don't restore completion handlers
- Issue #776<sup>5181</sup> - Compiler chokes on dataflow overload with launch policy
- Issue #775<sup>5182</sup> - Runtime error with local dataflow (copying futures?)
- Issue #774<sup>5183</sup> - Using local dataflow without explicit namespace
- Issue #773<sup>5184</sup> - Local dataflow with unwrap: functor operators need to be const
- Issue #772<sup>5185</sup> - Allow (remote) actions to return a future
- Issue #771<sup>5186</sup> - Setting HPX\_LIMIT gives huge boost MPL errors
- Issue #770<sup>5187</sup> - Add launch policy to (local) dataflow
- Issue #769<sup>5188</sup> - Make compile time configuration information available
- Issue #768<sup>5189</sup> - Const correctness problem in local dataflow
- Issue #767<sup>5190</sup> - Add launch policies to async
- Issue #766<sup>5191</sup> - Mark data structures for optimized (array based) serialization
- Issue #765<sup>5192</sup> - Align hpx::any with N3508: Any Library Proposal (Revision 2)
- Issue #764<sup>5193</sup> - Align hpx::future with newest N3558: A Standardized Representation of Asynchronous Operations

- Issue #762<sup>5194</sup> - added a human readable output for the ping pong example
- Issue #761<sup>5195</sup> - Ambiguous typename when constructing derived component
- Issue #760<sup>5196</sup> - Simple components can not be derived
- Issue #759<sup>5197</sup> - make install doesn't give a complete install
- Issue #758<sup>5198</sup> - Stack overflow when using locking\_hook<>
- Issue #757<sup>5199</sup> - copy paste error; unsupported function overloading
- Issue #756<sup>5200</sup> - GTCX runtime issue in Gordon
- Issue #755<sup>5201</sup> - Papi counters don't work with reset and evaluate API's
- Issue #753<sup>5202</sup> - cmake bugfix and improved component action docs
- Issue #752<sup>5203</sup> - hpx simple component docs
- Issue #750<sup>5204</sup> - Add hpx::util::any
- Issue #749<sup>5205</sup> - Thread phase counter is not reset
- Issue #748<sup>5206</sup> - Memory performance counter are not registered
- Issue #747<sup>5207</sup> - Create performance counters exposing arithmetic operations
- Issue #745<sup>5208</sup> - apply\_callback needs to invoke callback when applied locally
- Issue #744<sup>5209</sup> - CMake fixes
- Issue #743<sup>5210</sup> - Problem Building github version of HPX
- Issue #742<sup>5211</sup> - Remove HPX\_STD\_BIND
- Issue #741<sup>5212</sup> - assertion 'px != 0' failed: HPX(assertion\_failure) for low numbers of OS threads
- Issue #739<sup>5213</sup> - Performance counters do not count to the end of the program or evaluation
- Issue #738<sup>5214</sup> - Dedicated AGAS server runs don't work; console ignores -a option.
- Issue #737<sup>5215</sup> - Missing bind overloads
- Issue #736<sup>5216</sup> - Performance counter wildcards do not always work

- Issue #735<sup>5217</sup> - Create native ibverbs parcelport based on rdma operations
- Issue #734<sup>5218</sup> - Threads stolen performance counter total is incorrect
- Issue #733<sup>5219</sup> - Test benchmarks need to be checked and fixed
- Issue #732<sup>5220</sup> - Build fails with Mac, using mac ports clang-3.3 on latest git branch
- Issue #731<sup>5221</sup> - Add global start/stop API for performance counters
- Issue #730<sup>5222</sup> - Performance counter values are apparently incorrect
- Issue #729<sup>5223</sup> - Unhandled switch
- Issue #728<sup>5224</sup> - Serialization of hpx::util::function between two localities causes seg faults
- Issue #727<sup>5225</sup> - Memory counters on Mac OS X
- Issue #725<sup>5226</sup> - Restore original thread priority on resume
- Issue #724<sup>5227</sup> - Performance benchmarks do not depend on main HPX libraries
- Issue #723<sup>5228</sup> - [teletype]–hpx:nodes=``cat \$PBS\_NODEFILE`` works; –hpx:nodefile=\$PBS\_NODEFILE does not.[c++]
- Issue #722<sup>5229</sup> - Fix binding const member functions as actions
- Issue #719<sup>5230</sup> - Create performance counter exposing compression ratio
- Issue #718<sup>5231</sup> - Add possibility to compress parcel data
- Issue #717<sup>5232</sup> - strip\_credit\_from\_gid has misleading semantics
- Issue #716<sup>5233</sup> - Non-option arguments to programs run using pbsdsh must be before --hpx:nodes, contrary to directions
- Issue #715<sup>5234</sup> - Re-thrown exceptions should retain the original call site
- Issue #714<sup>5235</sup> - failed assertion in debug mode
- Issue #713<sup>5236</sup> - Add performance counters monitoring connection caches
- Issue #712<sup>5237</sup> - Adjust parcel related performance counters to be connection type specific
- Issue #711<sup>5238</sup> - configuration failure

<sup>5238</sup> <https://github.com/STELLAR-GROUP/hpx/issues/711>

- Issue #710<sup>5239</sup> - Error “timed out while trying to find room in the connection cache” when trying to start multiple localities on a single computer
- Issue #709<sup>5240</sup> - Add new thread state ‘staged’ referring to task descriptions
- Issue #708<sup>5241</sup> - Detect/mitigate bad non-system installs of GCC on Redhat systems
- Issue #707<sup>5242</sup> - Many examples do not link with Git HEAD version
- Issue #706<sup>5243</sup> - `hpx::init` removes portions of non-option command line arguments before last = sign
- Issue #705<sup>5244</sup> - Create rolling average and median aggregating performance counters
- Issue #704<sup>5245</sup> - Create performance counter to expose thread queue waiting time
- Issue #703<sup>5246</sup> - Add support to HPX build system to find libcrtool.a and related headers
- Issue #699<sup>5247</sup> - Generalize instrumentation support
- Issue #698<sup>5248</sup> - compilation failure with hwloc absent
- Issue #697<sup>5249</sup> - Performance counter counts should be zero indexed
- Issue #696<sup>5250</sup> - Distributed problem
- Issue #695<sup>5251</sup> - Bad perf counter time printed
- Issue #693<sup>5252</sup> - --help doesn't print component specific command line options
- Issue #692<sup>5253</sup> - SLURM support broken
- Issue #691<sup>5254</sup> - exception while executing any application linked with hwloc
- Issue #690<sup>5255</sup> - `thread_id_test` and `thread_launcher_test` failing
- Issue #689<sup>5256</sup> - Make the buildbots use hwloc
- Issue #687<sup>5257</sup> - compilation error fix (hwloc\_topology)
- Issue #686<sup>5258</sup> - Linker Error for Applications
- Issue #684<sup>5259</sup> - Pinning of service thread fails when number of worker threads equals the number of cores
- Issue #682<sup>5260</sup> - Add performance counters exposing number of stolen threads
- Issue #681<sup>5261</sup> - Add apply\_continue for asynchronous chaining of actions

- Issue #557<sup>5285</sup> - Remove action codes
- Issue #531<sup>5286</sup> - AGAS request and response classes should use switch statements
- Issue #529<sup>5287</sup> - Investigate the state of hwloc support
- Issue #526<sup>5288</sup> - Make HPX aware of hyper-threading
- Issue #518<sup>5289</sup> - Create facilities allowing to use plain arrays as action arguments
- Issue #473<sup>5290</sup> - hwloc thread binding is broken on CPUs with hyperthreading
- Issue #383<sup>5291</sup> - Change result type detection for hpx::util::bind to use result\_of protocol
- Issue #341<sup>5292</sup> - Consolidate route code
- Issue #219<sup>5293</sup> - Only copy arguments into actions once
- Issue #177<sup>5294</sup> - Implement distributed AGAS
- Issue #43<sup>5295</sup> - Support for Darwin (Xcode + Clang)

## 2.10.21 HPX V0.9.5 (Jan 16, 2013)

We have had over 1000 commits since the last release and we have closed roughly 150 tickets (bugs, feature requests, etc.).

### General changes

This release is continuing along the lines of code and API consolidation, and overall usability improvements. We dedicated much attention to performance and we were able to significantly improve the threading and networking subsystems.

We successfully ported *HPX* to the Android platform. *HPX* applications now not only can run on mobile devices, but we support heterogeneous applications running across architecture boundaries. At the Supercomputing Conference 2012 we demonstrated connecting Android tablets to simulations running on a Linux cluster. The Android tablet was used to query performance counters from the Linux simulation and to steer its parameters.

We successfully ported *HPX* to Mac OSX (using the Clang compiler). Thanks to Pyry Jähkälä for contributing the corresponding patches. Please see the section `macos_installation` for more details.

We made a special effort to make *HPX* usable in highly concurrent use cases. Many of the *HPX* API functions which possibly take longer than 100 microseconds to execute now can be invoked asynchronously. We added uniform support for composing futures which simplifies to write asynchronous code. *HPX* actions (function objects encapsulating possibly concurrent remote function invocations) are now well integrated with all other API facilities such like `hpx::bind`.

All of the API has been aligned as much as possible with established paradigms. *HPX* now mirrors many of the facilities as defined in the C++11 Standard, such as `hpx::thread`, `hpx::function`, `hpx::future`, etc.

<sup>5285</sup> <https://github.com/STELLAR-GROUP/hpx/issues/557>

<sup>5286</sup> <https://github.com/STELLAR-GROUP/hpx/issues/531>

<sup>5287</sup> <https://github.com/STELLAR-GROUP/hpx/issues/529>

<sup>5288</sup> <https://github.com/STELLAR-GROUP/hpx/issues/526>

5289 <https://github.com/STELLAR-GROUP/hpx/issues/518>5290 <https://github.com/STELLAR-GROUP/hpx/issues/473>5291 <https://github.com/STELLAR-GROUP/hpx/issues/383>5292 <https://github.com/STELLAR-GROUP/hpx/issues/341>5293 <https://github.com/STELLAR-GROUP/hpx/issues/219>5294 <https://github.com/STELLAR-GROUP/hpx/issues/177>5295 <https://github.com/STELLAR-GROUP/hpx/issues/43>

A lot of work has been put into improving the documentation. Many of the API functions are documented now, concepts are explained in detail, and examples are better described than before. The new documentation index enables finding information with lesser effort.

This is the first release of HPX we perform after the move to [Github<sup>5296</sup>](#) This step has enabled a wider participation from the community and further encourages us in our decision to release HPX as a true open source library (HPX is licensed under the very liberal [Boost Software License<sup>5297</sup>](#)).

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release. This is by far the longest list of newly implemented features and fixed issues for any of HPX' releases so far.

- Issue #666<sup>5298</sup> - Segfault on calling hpx::finalize twice
- Issue #665<sup>5299</sup> - Adding declaration num\_of\_cores
- Issue #662<sup>5300</sup> - pkgconfig is building wrong
- Issue #660<sup>5301</sup> - Need uninterrupt function
- Issue #659<sup>5302</sup> - Move our logging library into a different namespace
- Issue #658<sup>5303</sup> - Dynamic performance counter types are broken
- Issue #657<sup>5304</sup> - HPX v0.9.5 (RC1) hello\_world example segfaulting
- Issue #656<sup>5305</sup> - Define the affinity of parcel-pool, io-pool, and timer-pool threads
- Issue #654<sup>5306</sup> - Integrate the Boost auto\_index tool with documentation
- Issue #653<sup>5307</sup> - Make HPX build on OS X + Clang + libc++
- Issue #651<sup>5308</sup> - Add fine-grained control for thread pinning
- Issue #650<sup>5309</sup> - Command line no error message when using -hpx:(anything)
- Issue #645<sup>5310</sup> - Command line aliases don't work in [teletype]``@file``[c++]
- Issue #644<sup>5311</sup> - Terminated threads are not always properly cleaned up
- Issue #640<sup>5312</sup> - future\_data<T>::set\_on\_completed\_ used without locks
- Issue #638<sup>5313</sup> - hpx build with intel compilers fails on linux
- Issue #637<sup>5314</sup> - --copy-dt-needed-entries breaks with gold

<sup>5314</sup> <https://github.com/STELLAR-GROUP/hpx/issues/637>

- Issue #635<sup>5315</sup> - Boost V1.53 will add Boost.Lockfree and Boost.Atomic
- Issue #633<sup>5316</sup> - Re-add examples to final 0.9.5 release
- Issue #632<sup>5317</sup> - Example `thread_aware_timer` is broken
- Issue #631<sup>5318</sup> - FFT application throws error in parcellayer
- Issue #630<sup>5319</sup> - Event synchronization example is broken
- Issue #629<sup>5320</sup> - Waiting on futures hangs
- Issue #628<sup>5321</sup> - Add an `HPX_ALWAYS_ASSERT` macro
- Issue #625<sup>5322</sup> - Port coroutines context switch benchmark
- Issue #621<sup>5323</sup> - New INI section for stack sizes
- Issue #618<sup>5324</sup> - `pkg_config` support does not work with a HPX debug build
- Issue #617<sup>5325</sup> - `hpx/external/logging/boost/logging/detail/cache_before_init.hpp:139:67: error: 'get_thread_id'` was not declared in this scope
- Issue #616<sup>5326</sup> - Change `wait_xxx` not to use locking
- Issue #615<sup>5327</sup> - Revert visibility ‘fix’ (`fb0b6b8245dad1127b0c25ebaf9386b3945cca9`)
- Issue #614<sup>5328</sup> - Fix Dataflow linker error
- Issue #613<sup>5329</sup> - `find_here` should throw an exception on failure
- Issue #612<sup>5330</sup> - Thread phase doesn’t show up in debug mode
- Issue #611<sup>5331</sup> - Make stack guard pages configurable at runtime (initialization time)
- Issue #610<sup>5332</sup> - Co-Locate Components
- Issue #609<sup>5333</sup> - `future_overhead`
- Issue #608<sup>5334</sup> - `--hpx:list-counter-infos` problem
- Issue #607<sup>5335</sup> - Update Boost.Context based backend for coroutines
- Issue #606<sup>5336</sup> - `1d_wave_equation` is not working
- Issue #605<sup>5337</sup> - Any C++ function that has serializable arguments and a serializable return type should be re-

## notable

- Issue #604<sup>5338</sup> - Connecting localities isn't working anymore
- Issue #603<sup>5339</sup> - Do not verify any ini entries read from a file
- Issue #602<sup>5340</sup> - Rename argument\_size to type\_size/ added implementation to get parcel size
- Issue #599<sup>5341</sup> - Enable locality specific command line options
- Issue #598<sup>5342</sup> - Need an API that accesses the performance counter reporting the system uptime
- Issue #597<sup>5343</sup> - compiling on ranger
- Issue #595<sup>5344</sup> - I need a place to store data in a thread self pointer
- Issue #594<sup>5345</sup> - 32/64 interoperability
- Issue #593<sup>5346</sup> - Warn if logging is disabled at compile time but requested at runtime
- Issue #592<sup>5347</sup> - Add optional argument value to --hpx:list-counters and --hpx:list-counter-infos
- Issue #591<sup>5348</sup> - Allow for wildcards in performance counter names specified with --hpx:print-counter
- Issue #590<sup>5349</sup> - Local promise semantic differences
- Issue #589<sup>5350</sup> - Create API to query performance counter names
- Issue #587<sup>5351</sup> - Add get\_num\_localities and get\_num\_threads to AGAS API
- Issue #586<sup>5352</sup> - Adjust local AGAS cache size based on number of localities
- Issue #585<sup>5353</sup> - Error while using counters in HPX
- Issue #584<sup>5354</sup> - counting argument size of actions, initial pass.
- Issue #581<sup>5355</sup> - Remove RemoteResult template parameter for future<>
- Issue #580<sup>5356</sup> - Add possibility to hook into actions
- Issue #578<sup>5357</sup> - Use angle brackets in HPX error dumps
- Issue #576<sup>5358</sup> - Exception incorrectly thrown when --help is used
- Issue #575<sup>5359</sup> - HPX(bad\_component\_type) with gcc 4.7.2 and boost 1.51

<sup>5359</sup> <https://github.com/STELLAR-GROUP/hpx/issues/575>

- Issue #574<sup>5360</sup> - --hpx:connect command line parameter not working correctly
- Issue #571<sup>5361</sup> - hpx::wait() (callback version) should pass the future to the callback function
- Issue #570<sup>5362</sup> - hpx::wait should operate on boost::arrays and std::lists
- Issue #569<sup>5363</sup> - Add a logging sink for Android
- Issue #568<sup>5364</sup> - 2-argument version of HPX\_DEFINE\_COMPONENT\_ACTION
- Issue #567<sup>5365</sup> - Connecting to a running HPX application works only once
- Issue #565<sup>5366</sup> - HPX doesn't shutdown properly
- Issue #564<sup>5367</sup> - Partial preprocessing of new component creation interface
- Issue #563<sup>5368</sup> - Add hpx::start/hpx::stop to avoid blocking main thread
- Issue #562<sup>5369</sup> - All command line arguments swallowed by hpx
- Issue #561<sup>5370</sup> - Boost.Tuple is not move aware
- Issue #558<sup>5371</sup> - boost::shared\_ptr<> style semantics/syntax for client classes
- Issue #556<sup>5372</sup> - Creation of partially preprocessed headers should be enabled for Boost newer than V1.50
- Issue #555<sup>5373</sup> - BOOST\_FORCEINLINE does not name a type
- Issue #554<sup>5374</sup> - Possible race condition in thread get\_id()
- Issue #552<sup>5375</sup> - Move enable client\_base
- Issue #550<sup>5376</sup> - Add stack size category 'huge'
- Issue #549<sup>5377</sup> - ShenEOS run seg-faults on single or distributed runs
- Issue #545<sup>5378</sup> - AUTOGLOB broken for add\_hpx\_component
- Issue #542<sup>5379</sup> - FindHPX\_HDF5 still searches multiple times
- Issue #541<sup>5380</sup> - Quotes around application name in hpx::init
- Issue #539<sup>5381</sup> - Race condition occurring with new lightweight threads
- Issue #535<sup>5382</sup> - hpx\_run\_tests.py exits with no error code when tests are missing

- Issue #530<sup>5383</sup> - Thread description(<unknown>) in logs
- Issue #523<sup>5384</sup> - Make thread objects more lightweight
- Issue #521<sup>5385</sup> - `hpx::error_code` is not usable for lightweight error handling
- Issue #520<sup>5386</sup> - Add full user environment to HPX logs
- Issue #519<sup>5387</sup> - Build succeeds, running fails
- Issue #517<sup>5388</sup> - Add a guard page to linux coroutine stacks
- Issue #516<sup>5389</sup> - `hpx::thread::detach` suspends while holding locks, leads to hang in debug
- Issue #514<sup>5390</sup> - Preprocessed headers for <hpx/apply.hpp> don't compile
- Issue #513<sup>5391</sup> - Buildbot configuration problem
- Issue #512<sup>5392</sup> - Implement action based stack size customization
- Issue #511<sup>5393</sup> - Move action priority into a separate type trait
- Issue #510<sup>5394</sup> - trunk broken
- Issue #507<sup>5395</sup> - no matching function for call to `boost::scoped_ptr<hpx::threads::topology>::scoped_ptr(hpx::thre`
- Issue #505<sup>5396</sup> - undefined\_symbol regression test currently failing
- Issue #502<sup>5397</sup> - Adding OpenCL and OCLM support to HPX for Windows and Linux
- Issue #501<sup>5398</sup> - `find_package(HPX)` sets cmake output variables
- Issue #500<sup>5399</sup> - `wait_any/wait_all` are badly named
- Issue #499<sup>5400</sup> - Add support for disabling pbs support in pbs runs
- Issue #498<sup>5401</sup> - Error during no-cache runs
- Issue #496<sup>5402</sup> - Add partial preprocessing support to cmake
- Issue #495<sup>5403</sup> - Support HPX modules exporting startup/shutdown functions only
- Issue #494<sup>5404</sup> - Allow modules to specify when to run startup/shutdown functions
- Issue #493<sup>5405</sup> - Avoid constructing a string in `make_success_code`

- Issue #492<sup>5406</sup> - Performance counter creation is no longer synchronized at startup
- Issue #491<sup>5407</sup> - Performance counter creation is no longer synchronized at startup
- Issue #490<sup>5408</sup> - Sheneos on\_completed\_bulk seg fault in distributed
- Issue #489<sup>5409</sup> - compiling issue with g++44
- Issue #488<sup>5410</sup> - Adding OpenCL and OCLM support to HPX for the MSVC platform
- Issue #487<sup>5411</sup> - FindHPX.cmake problems
- Issue #485<sup>5412</sup> - Change distributing\_factory and binpacking\_factory to use bulk creation
- Issue #484<sup>5413</sup> - Change HPX\_DONT\_USE\_PREPROCESSED\_FILES to HPX\_USE\_PREPROCESSED\_FILES
- Issue #483<sup>5414</sup> - Memory counter for Windows
- Issue #479<sup>5415</sup> - strange errors appear when requesting performance counters on multiple nodes
- Issue #477<sup>5416</sup> - Create (global) timer for multi-threaded measurements
- Issue #472<sup>5417</sup> - Add partial preprocessing using Wave
- Issue #471<sup>5418</sup> - Segfault stack traces don't show up in release
- Issue #468<sup>5419</sup> - External projects need to link with internal components
- Issue #462<sup>5420</sup> - Startup/shutdown functions are called more than once
- Issue #458<sup>5421</sup> - Consolidate hpx::util::high\_resolution\_timer and hpx::util::high\_resolution\_clock
- Issue #457<sup>5422</sup> - index out of bounds in allgather\_and\_gate on 4 cores or more
- Issue #448<sup>5423</sup> - Make HPX compile with clang
- Issue #447<sup>5424</sup> - ‘make tests’ should execute tests on local installation
- Issue #446<sup>5425</sup> - Remove SVN-related code from the codebase
- Issue #444<sup>5426</sup> - race condition in smp
- Issue #441<sup>5427</sup> - Patched Boost.Serialization headers should only be installed if needed
- Issue #439<sup>5428</sup> - Components using HPX\_REGISTER\_STARTUP\_MODULE fail to compile with MSVC

## 2.10.22 HPX V0.9.0 (Jul 5, 2012)

We have had roughly 800 commits since the last release and we have closed approximately 80 tickets (bugs, feature requests, etc.).

### General changes

- Significant improvements made to the usability of *HPX* in large-scale, distributed environments.
- Renamed `hpx::lcos::packaged_task` to `hpx::lcos::packaged_action` to reflect the semantic differences to a `packaged_task` as defined by the C++11 Standard<sup>5454</sup>.
- *HPX* now exposes `hpx::thread` which is compliant to the C++11 `std::thread` type except that it (purely locally) represents an *HPX* thread. This new type does not expose any of the remote capabilities of the underlying *HPX*-thread implementation.
- The type `hpx::lcos::future` is now compliant to the C++11 `std::future<>` type. This type can be used to synchronize both, local and remote operations. In both cases the control flow will ‘return’ to the future in order to trigger any continuation.
- The types `hpx::lcos::local::promise` and `hpx::lcos::local::packaged_task` are now compliant to the C++11 `std::promise<>` and `std::packaged_task<>` types. These can be used to create a future representing local work only. Use the types `hpx::lcos::promise` and `hpx::lcos::packaged_action` to wrap any (possibly remote) action into a future.
- `hpx::thread` and `hpx::lcos::future` are now cancelable.
- Added support for sequential and logic composition of `hpx::lcos::futures`. The member function `hpx::lcos::future::when` permits futures to be sequentially composed. The helper functions `hpx::wait_all`, `hpx::wait_any`, and `hpx::wait_n` can be used to wait for more than one future at a time.
- *HPX* now exposes `hpx::apply` and `hpx::async` as the preferred way of creating (or invoking) any deferred work. These functions are usable with various types of functions, function objects, and actions and provide a uniform way to spawn deferred tasks.
- *HPX* now utilizes `hpx::util::bind` to (partially) bind local functions and function objects, and also actions. Remote bound actions can have placeholders as well.
- *HPX* continuations are now fully polymorphic. The class `hpx::actions::forwarding_continuation` is an example of how the user can write their own types of continuations. It can be used to execute any function as an continuation of a particular action.
- Reworked the action invocation API to be fully conformant to normal functions. Actions can now be invoked using `hpx::apply`, `hpx::async`, or using the `operator()` implemented on actions. Actions themselves can now be cheaply instantiated as they do not have any members anymore.
- Reworked the lazy action invocation API. Actions can now be directly bound using `hpx::util::bind` by passing an action instance as the first argument.
- A minimal *HPX* program now looks like this:

<sup>5452</sup> <https://github.com/STELLAR-GROUP/hpx/issues/48>

<sup>5453</sup> <https://github.com/STELLAR-GROUP/hpx/issues/21>

<sup>5454</sup> <http://www.open-std.org/jtc1/sc22/wg21>

```
#include <hpx/hpx_init.hpp>

int hpx_main()
{
    return hpx::finalize();
}

int main()
{
    return hpx::init();
}
```

This removes the immediate dependency on the Boost.Program Options<sup>5455</sup> library.

---

**Note:** This minimal version of an HPX program does not support any of the default command line arguments (such as –help, or command line options related to PBS). It is suggested to always pass argc and argv to HPX as shown in the example below.

---

- In order to support those, but still not to depend on Boost.Program Options<sup>5456</sup>, the minimal program can be written as:

```
#include <hpx/hpx_init.hpp>

// The arguments for hpx_main can be left off, which very similar to the
// behavior of `main()` as defined by C++.
int hpx_main(int argc, char* argv[])
{
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```

- Added performance counters exposing the number of component instances which are alive on a given locality.
- Added performance counters exposing then number of messages sent and received, the number of parcels sent and received, the number of bytes sent and received, the overall time required to send and receive data, and the overall time required to serialize and deserialize the data.
- Added a new component: `hpx::components::binpacking_factory` which is equivalent to the existing `hpx::components::distributing_factory` component, except that it equalizes the overall population of the components to create. It exposes two factory methods, one based on the number of existing instances of the component type to create, and one based on an arbitrary performance counter which will be queried for all relevant localities.
- Added API functions allowing to access elements of the diagnostic information embedded in the given exception: `hpx::get_locality_id`, `hpx::get_host_name`, `hpx::get_process_id`, `hpx::get_function_name`, `hpx::get_file_name`, `hpx::get_line_number`, `hpx::get_os_thread`, `hpx::get_thread_id`, and `hpx::get_thread_description`.

<sup>5456</sup> [https://www.boost.org/doc/html/program\\_options.html](https://www.boost.org/doc/html/program_options.html)

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #71<sup>5457</sup> - GIDs that are not serialized via `handle_gid`<> should raise an exception
- Issue #105<sup>5458</sup> - Allow for `hpx::util::functions` to be registered in the AGAS symbolic namespace
- Issue #107<sup>5459</sup> - Nasty threadmanger race condition (reproducible in `sheneos_test`)
- Issue #108<sup>5460</sup> - Add millisecond resolution to *HPX* logs on Linux
- Issue #110<sup>5461</sup> - Shutdown hang in distributed with release build
- Issue #116<sup>5462</sup> - Don't use TSS for the applier and runtime pointers
- Issue #162<sup>5463</sup> - Move local synchronous execution shortcut from `hpx::function` to the applier
- Issue #172<sup>5464</sup> - Cache sources in CMake and check if they change manually
- Issue #178<sup>5465</sup> - Add an INI option to turn off ranged-based AGAS caching
- Issue #187<sup>5466</sup> - Support for disabling performance counter deployment
- Issue #202<sup>5467</sup> - Support for sending performance counter data to a specific file
- Issue #218<sup>5468</sup> - boost.coroutines allows different stack sizes, but stack pool is unaware of this
- Issue #231<sup>5469</sup> - Implement movable `boost::bind`
- Issue #232<sup>5470</sup> - Implement movable `boost::function`
- Issue #236<sup>5471</sup> - Allow binding `hpx::util::function` to actions
- Issue #239<sup>5472</sup> - Replace `hpx::function` with `hpx::util::function`
- Issue #240<sup>5473</sup> - Can't specify `RemoteResult` with `lcos::async`
- Issue #242<sup>5474</sup> - `REGISTER_TEMPLATE` support for plain actions
- Issue #243<sup>5475</sup> - `handle_gid`<> support for `hpx::util::function`
- Issue #245<sup>5476</sup> - `*_c_cache` code throws an exception if the queried GID is not in the local cache
- Issue #246<sup>5477</sup> - Undefined references in dataflow/adaptive1d example

<sup>5518</sup> <https://github.com/STELLAR-GROUP/hpx/issues/426>

## General changes

- HPX does not need to be installed anymore to be functional.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this point release:

- Issue #295<sup>5519</sup> - Don't require install path to be known at compile time.
- Issue #371<sup>5520</sup> - Add hpx iostreams to standard build.
- Issue #384<sup>5521</sup> - Fix compilation with GCC 4.7.
- Issue #390<sup>5522</sup> - Remove keep\_factory\_alive startup call from ShenEOS; add shutdown call to H5close.
- Issue #393<sup>5523</sup> - Thread affinity control is broken.

## Bug fixes (commits)

Here is a list of the important commits included in this point release:

- r7642 - External: Fix backtrace memory violation.
- **r7775 - Components: Fix symbol visibility bug with component startup** providers. This prevents one components providers from overriding another components.
- r7778 - Components: Fix startup/shutdown provider shadowing issues.

## 2.10.24 HPX V0.8.0 (Mar 23, 2012)

We have had roughly 1000 commits since the last release and we have closed approximately 70 tickets (bugs, feature requests, etc.).

## General changes

- Improved PBS support, allowing for arbitrary naming schemes of node-hostnames.
- Finished verification of the reference counting framework.
- Implemented decrement merging logic to optimize the distributed reference counting system.
- Restructured the LCO framework. Renamed `hpx::lcos::eager_future`< `and` `hpx::lcos::lazy_future`> into `hpx::lcos::packaged_task` and `hpx::lcos::deferred_packaged_task`. Split `hpx::lcos::promise` into `hpx::lcos::packaged_task` and `hpx::lcos::future`. Added 'local' futures (in namespace `hpx::lcos::local`).
- Improved the general performance of local and remote action invocations. This (under certain circumstances) drastically reduces the number of copies created for each of the parameters and return values.

<sup>5519</sup> <https://github.com/STELLAR-GROUP/hpx/issues/295>

<sup>5520</sup> <https://github.com/STELLAR-GROUP/hpx/issues/371>

<sup>5521</sup> <https://github.com/STELLAR-GROUP/hpx/issues/384>

<sup>5522</sup> <https://github.com/STELLAR-GROUP/hpx/issues/390>

<sup>5523</sup> <https://github.com/STELLAR-GROUP/hpx/issues/393>

- Reworked the performance counter framework. Performance counters are now created only when needed, which reduces the overall resource requirements. The new framework allows for much more flexible creation and management of performance counters. The new sine example application demonstrates some of the capabilities of the new infrastructure.
- Added a buildbot-based continuous build system which gives instant, automated feedback on each commit to SVN.
- Added more automated tests to verify proper functioning of *HPX*.
- Started to create documentation for *HPX* and its API.
- Added documentation toolchain to the build system.
- Added dataflow LCO.
- Changed default *HPX* command line options to have `hpx:` prefix. For instance, the former option `--threads` is now `--hpx:threads`. This has been done to make ambiguities with possible application specific command line options as unlikely as possible. See the section *HPX Command Line Options* for a full list of available options.
- Added the possibility to define command line aliases. The former short (one-letter) command line options have been predefined as aliases for backwards compatibility. See the section *HPX Command Line Options* for a detailed description of command line option aliasing.
- Network connections are now cached based on the connected host. The number of simultaneous connections to a particular host is now limited. Parcels are buffered and bundled if all connections are in use.
- Added more refined thread affinity control. This is based on the external library Portable Hardware Locality (HWLOC).
- Improved support for Windows builds with CMake.
- Added support for components to register their own command line options.
- Added the possibility to register custom startup/shutdown functions for any component. These functions are guaranteed to be executed by an *HPX* thread.
- Added two new experimental thread schedulers: `hierarchy_scheduler` and `periodic_priority_scheduler`. These can be activated by using the command line options `--hpx:queuing=hierarchy` or `--hpx:queuing=periodic`.

## Example applications

- Graph500 performance benchmark<sup>5524</sup> (thanks to Matthew Anderson for contributing this application).
- GTC (Gyrokinetic Toroidal Code)<sup>5525</sup>: a skeleton for particle in cell type codes.
- Random Memory Access: an example demonstrating random memory accesses in a large array
- ShenEOS example<sup>5526</sup>, demonstrating partitioning of large read-only data structures and exposing an interpolation API.
- Sine performance counter demo.
- Accumulator examples demonstrating how to write and use *HPX* components.
- Quickstart examples (like `hello_world`, `fibonacci`, `quicksort`, `factorial`, etc.) demonstrating simple *HPX* concepts which introduce some of the concepts in *HPX*.
- Load balancing and work stealing demos.

## API changes

- Moved all local LCOs into a separate namespace `hpx::lcos::local` (for instance, `hpx::lcos::local_mutex` is now `hpx::lcos::local::mutex`).
- Replaced `hpx::actions::function` with `hpx::util::function`. Cleaned up related code.
- Removed `hpx::traits::handle_gid` and moved handling of global reference counts into the corresponding serialization code.
- Changed terminology: `prefix` is now called `locality_id`, renamed the corresponding API functions (such as `hpx::get_prefix`, which is now called `hpx::get_locality_id`).
- Adding `hpx::find_remote_localities`, and `hpx::get_num_localities`.
- Changed performance counter naming scheme to make it more bash friendly. The new performance counter naming scheme is now

```
/object{parentname#parentindex/instance#index}/counter#parameters
```

- Added `hpx::get_worker_thread_num` replacing `hpx::threadmanager_base::get_thread_num`.
- Renamed `hpx::get_num_os_threads` to `hpx::get_os_threads_count`.
- Added `hpx::threads::get_thread_count`.
- Restructured the Futures sub-system, renaming types in accordance with the terminology used by the C++11 ISO standard.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #31<sup>[5527](https://github.com/STELLAR-GROUP/hpx/issues/31)</sup> - Specialize handle\_gid<> for examples and tests
- Issue #72<sup>[5528](https://github.com/STELLAR-GROUP/hpx/issues/72)</sup> - Fix AGAS reference counting
- Issue #104<sup>[5529](https://github.com/STELLAR-GROUP/hpx/issues/104)</sup> - heartbeat throws an exception when derefing the performance counter it's watching
- Issue #111<sup>[5530](https://github.com/STELLAR-GROUP/hpx/issues/111)</sup> - throttle causes an exception on the target application
- Issue #142<sup>[5531](https://github.com/STELLAR-GROUP/hpx/issues/142)</sup> - One failed component loading causes an unrelated component to fail
- Issue #165<sup>[5532](https://github.com/STELLAR-GROUP/hpx/issues/165)</sup> - Remote exception propagation bug in AGAS reference counting test
- Issue #186<sup>[5533](https://github.com/STELLAR-GROUP/hpx/issues/186)</sup> - Test credit exhaustion/splitting (e.g. prepare\_gid and symbol NS)
- Issue #188<sup>[5534](https://github.com/STELLAR-GROUP/hpx/issues/188)</sup> - Implement remaining AGAS reference counting test cases
- Issue #258<sup>[5535](https://github.com/STELLAR-GROUP/hpx/issues/258)</sup> - No type checking of GIDs in stubs classes
- Issue #271<sup>[5536](https://github.com/STELLAR-GROUP/hpx/issues/271)</sup> - Seg fault/shared pointer assertion in distributed code

## General changes

- Completely removed code related to deprecated AGAS V1, started to work on AGAS V2.1.
- Started to clean up and streamline the exposed APIs (see ‘API changes’ below for more details).
- Revamped and unified performance counter framework, added a lot of new performance counter instances for monitoring of a diverse set of internal *HPX* parameters (queue lengths, access statistics, etc.).
- Improved general error handling and logging support.
- Fixed several race conditions, improved overall stability, decreased memory footprint, improved overall performance (major optimizations include native TLS support and ranged-based AGAS caching).
- Added support for running *HPX* applications with PBS.
- Many updates to the build system, added support for gcc 4.5.x and 4.6.x, added C++11 support.
- Many updates to default command line options.
- Added many tests, set up buildbot for continuous integration testing.
- Better shutdown handling of distributed applications.

## Example applications

- quickstart/factorial and quickstart/fibonacci, future-recursive parallel algorithms.
- quickstart/hello\_world, distributed hello world example.
- quickstart/rma, simple remote memory access example
- quickstart/quicksort, parallel quicksort implementation.
- gtc, gyrokinetic torodial code.
- bfs, breadth-first-search, example code for a graph application.
- sheneos, partitioning of large data sets.
- accumulator, simple component example.
- balancing/os\_thread\_num, balancing/px\_thread\_phase, examples demonstrating load balancing and work stealing.

## API changes

- Added `hpx::find_all_localities`.
- Added `hpx::terminate` for non-graceful termination of applications.
- Added `hpx::lcos::async` functions for simpler asynchronous programming.
- Added new AGAS interface for handling of symbolic namespace (`hpx::agas::*`).
- Renamed `hpx::components::wait` to `hpx::lcos::wait`.
- Renamed `hpx::lcos::future_value` to `hpx::lcos::promise`.
- Renamed `hpx::lcos::recursive_mutex` to `hpx::lcos::local_recursive_mutex`, `hpx::lcos::mutex` to `hpx::lcos::local_mutex`
- Removed support for Boost versions older than V1.38, recommended Boost version is now V1.47 and newer.
- Removed `hpx::process` (this will be replaced by a real process implementation in the future).

- Removed non-functional LCO code (`hpx::lcos::dataflow`, `hpx::lcos::thunk`, `hpx::lcos::dataflow_variable`).
- Removed deprecated `hpx::naming::full_address`.

## Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #28<sup>5576</sup> - Integrate Windows/Linux CMake code for *HPX* core
- Issue #32<sup>5577</sup> - `hpx::cout()` should be `hpx::cout`
- Issue #33<sup>5578</sup> - AGAS V2 legacy client does not properly handle `error_code`
- Issue #60<sup>5579</sup> - AGAS: allow for registerid to optionally take ownership of the gid
- Issue #62<sup>5580</sup> - adaptive1d compilation failure in Fusion
- Issue #64<sup>5581</sup> - Parcel subsystem doesn't resolve domain names
- Issue #83<sup>5582</sup> - No error handling if no console is available
- Issue #84<sup>5583</sup> - No error handling if a hosted locality is treated as the bootstrap server
- Issue #90<sup>5584</sup> - Add general commandline option `-N`
- Issue #91<sup>5585</sup> - Add possibility to read command line arguments from file
- Issue #92<sup>5586</sup> - Always log exceptions/errors to the log file
- Issue #93<sup>5587</sup> - Log the command line/program name
- Issue #95<sup>5588</sup> - Support for distributed launches
- Issue #97<sup>5589</sup> - Attempt to create a bad component type in AMR examples
- Issue #100<sup>5590</sup> - factorial and factorial\_get examples trigger AGAS component type assertions
- Issue #101<sup>5591</sup> - Segfault when `hpx::process::here()` is called in fibonacci2
- Issue #102<sup>5592</sup> - unknown\_component\_address in int\_object\_semaphore\_client
- Issue #114<sup>5593</sup> - marduk raises assertion with default parameters
- Issue #115<sup>5594</sup> - Logging messages for SMP runs (on the console) shouldn't be buffered

- Issue #277<sup>5651</sup> - Invalid CMake logic for Windows

## 2.11 Citing HPX

Please cite *HPX* whenever you use it for publications. Use our paper in The Journal of Open Source Software as the main citation for *HPX*:<sup>5652</sup>. Use the Zenodo entry for referring to the latest version of *HPX*:<sup>5653</sup>. Entries for citing specific versions of *HPX* can also be found at<sup>5654</sup>.

## 2.12 HPX users

A list of institutions and projects using *HPX* can be found on the *HPX* Users<sup>5655</sup> page.

## 2.13 About HPX

### 2.13.1 History

The development of High Performance ParalleX (*HPX*) began in 2007. At that time, Hartmut Kaiser became interested in the work done by the ParalleX group at the Center for Computation and Technology (CCT)<sup>5656</sup>, a multi-disciplinary

research institute at Louisiana State University (LSU)<sup>5657</sup>. The ParalleX group was working to develop a new and experimental execution model for future high performance computing architectures. This model was christened ParalleX. The first implementations of ParalleX were crude, and many of those designs had to be discarded entirely. However, over time the team learned quite a bit about how to design a parallel, distributed runtime system which implements the concepts of ParalleX.

From the very beginning, this endeavour has been a group effort. In addition to a handful of interested researchers, there have always been graduate and undergraduate students participating in the discussions, design, and implementation of *HPX*. In 2011 we decided to formalize our collective research efforts by creating the STE||AR<sup>5658</sup> group (Systems Technology, Emergent Parallelism, and Algorithm Research). Over time, the team grew to include researchers around the country and the world. In 2014, the STE||AR<sup>5659</sup> Group was reorganized to become the international community it is today. This consortium of researchers aims to develop stable, sustainable, and scalable tools which will enable application developers to exploit the parallelism latent in the machines of today and tomorrow. Our goal of the *HPX* project is to create a high quality, freely available, open source implementation of ParalleX concepts for conventional and future systems by building a modular and standards conforming runtime system for SMP and distributed application environments. The API exposed by *HPX* is conformant to the interfaces defined by the C++ ISO Standard and adheres to the programming guidelines used by the Boost<sup>5660</sup> collection of C++ libraries. We steer the development of *HPX* with real world applications and aim to provide a smooth migration path for domain scientists.

To learn more about STE||AR<sup>5661</sup> and ParalleX, see *People* and *Why HPX?*.

## 2.13.2 People

The STE||AR<sup>5662</sup> Group (pronounced as stellar) stands for “Systems Technology, Emergent Parallelism, and Algorithm Research”. We are an international group of faculty, researchers, and students working at various institutions around the world. The goal of the STE||AR<sup>5663</sup> Group is to promote the development of scalable parallel applications by providing a community for ideas, a framework for collaboration, and a platform for communicating these concepts to the broader community.

Our work is focused on building technologies for scalable parallel applications. *HPX*, our general purpose C++ runtime system for parallel and distributed applications, is no exception. We use *HPX* for a broad range of scientific applications, helping scientists and developers to write code which scales better and shows better performance compared to more conventional programming models such as MPI.

*HPX* is based on *ParalleX* which is a new (and still experimental) parallel execution model aiming to overcome the limitations imposed by the current hardware and the techniques we use to write applications today. Our group focuses on two types of applications - those requiring excellent strong scaling, allowing for a dramatic reduction of execution time for fixed workloads and those needing highest level of sustained performance through massive parallelism. These applications are presently unable (through conventional practices) to effectively exploit a relatively small number of cores in a multi-core system. By extension, these application will not be able to exploit high-end exascale computing systems which are likely to employ hundreds of millions of such cores by the end of this decade.

Critical bottlenecks to the effective use of new generation high performance computing (HPC) systems include:

- *Starvation*: due to lack of usable application parallelism and means of managing it,
- *Overhead*: reduction to permit strong scalability, improve efficiency, and enable dynamic resource management,
- *Latency*: from remote access across system or to local memories,
- *Contention*: due to multicore chip I/O pins, memory banks, and system interconnects.

<sup>5657</sup> <https://www.lsu.edu>

<sup>5658</sup> <https://stellar-group.org>

<sup>5659</sup> <https://stellar-group.org>

<sup>5660</sup> <https://www.boost.org/>

<sup>5661</sup> <https://stellar-group.org>

<sup>5662</sup> <https://stellar-group.org>

<sup>5663</sup> <https://stellar-group.org>

The ParalleX model has been devised to address these challenges by enabling a new computing dynamic through the application of message-driven computation in a global address space context with lightweight synchronization. The work on *HPX* is centered around implementing the concepts as defined by the ParalleX model. *HPX* is currently targeted at conventional machines, such as classical Linux based Beowulf clusters and SMP nodes.

We fully understand that the success of *HPX* (and ParalleX) is very much the result of the work of many people. To see a list of who is contributing see our tables below.

## Acknowledgements

Thanks also to the following people who contributed directly or indirectly to the project through discussions, pull requests, documentation patches, etc.

- Dimitra Karatza, for her work on refactoring the documentation and providing a new user-friendly environment during and after Google Season of Docs 2021.
- Srinivas Yadav, for his work on SIMD support in algorithms before and during Google Summer of Code 2021.
- Akhil Nair, for his work on adapting algorithms to C++20 before and during Google Summer of Code 2021.
- Alexander Toktarev, for updating the parallel algorithm customization points to use `tag_fallback_invoke` for the default implementations.
- Brice Goglin, for reporting and helping fix issues related to the integration of `hwloc` in *HPX*.
- Giannis Gonidelis, for his work on the ranges adaptation during the Google Summer of Code 2020.
- Auriane Reverdell (Swiss National Supercomputing Centre<sup>5705</sup>), for her tireless work on refactoring our CMake setup and modularizing *HPX*.
- Christopher Hinz, for his work on refactoring our CMake setup.
- Weile Wei, for fixing *HPX* builds with CUDA on Summit.
- Severin Strobl, for fixing our CMake setup related to linking and adding new entry points to the *HPX* runtime.
- Rebecca Stobaugh, for her major documentation review and contributions during and after the 2019 Google Season of Documentation.
- Jan Melech, for adding automatic serialization of simple structs.
- Austin McCartney, for adding concept emulation of the Ranges TS bidirectional and random access iterator concepts.
- Marco Diers, reporting and fixing issues related PMIx.
- Maximilian Bremer, for reporting multiple issues and extending the component migration tests.
- Piotr Mikolajczyk, for his improvements and fixes to the set and count algorithms.
- Grant Rostig, for reporting several deficiencies on our web pages.
- Jakub Golinowski, for implementing an *HPX* backend for OpenCV and in the process improving documentation and reporting issues.
- Mikael Simberg (Swiss National Supercomputing Centre<sup>5706</sup>), for his tireless help cleaning up and maintaining *HPX*.

- Tianyi Zhang, for his work on HPXMP.
- Shahrzad Shirzad, for her contributions related to Phylanx.
- Christopher Ogle, for his contributions to the parallel algorithms.
- Surya Priy, for his work with statistic performance counters.
- Anushi Maheshwari, for her work on random number generation.
- Bruno Pitrus, for his work with parallel algorithms.
- Nikunj Gupta, for rewriting the implementation of `hpx_main.hpp` and for his fixes for tests.
- Christopher Taylor, for his interest in *HPX* and the fixes he provided.
- Shoshana Jakobovits, for her work on the resource partitioner.
- Denis Blank, who re-wrote our unwrapped function to accept plain values arbitrary containers, and properly deal with nested futures.
- Ajai V. George, who implemented several of the parallel algorithms.
- Taeguk Kwon, who worked on implementing parallel algorithms as well as adapting the parallel algorithms to the Ranges TS.
- Zach Byerly ([Louisiana State University \(LSU\)](#)<sup>5707</sup>), who in his work developing applications on top of *HPX* opened tickets and contributed to the *HPX* examples.
- Daniel Estermann, for his work porting *HPX* to the Raspberry Pi.
- Alireza Kheirkhahan ([Louisiana State University \(LSU\)](#)<sup>5708</sup>), who built and administered our local cluster as well as his work in distributed IO.
- Abhimanyu Rawat, who worked on stack overflow detection.
- David Pfander, who improved signal handling in *HPX*, provided his optimization expertise, and worked on incorporating the Vc vectorization into *HPX*.
- Denis Demidov, who contributed his insights with VexCL.
- Khalid Hasanov, who contributed changes which allowed to run *HPX* on 64Bit power-pc architectures.
- Zahra Khatami ([Louisiana State University \(LSU\)](#)<sup>5709</sup>), who contributed the prefetching iterators and the persistent auto chunking executor parameters implementation.
- Marcin Copik, who worked on implementing GPU support for C++AMP and HCC. He also worked on implementing a HCC backend for *HPX*.*Compute*.
- Minh-Khanh Do, who contributed the implementation of several segmented algorithms.
- Bibek Wagle ([Louisiana State University \(LSU\)](#)<sup>5710</sup>), who worked on fixing and analyzing the performance of the *parcel* coalescing plugin in *HPX*.
- Lukas Troska, who reported several problems and contributed various test cases allowing to reproduce the corresponding issues.
- Andreas Schaefer, who worked on integrating his library ([LibGeoDecomp](#)<sup>5711</sup>) with *HPX*. He reported various problems and submitted several patches to fix issues allowing for a better integration with [LibGeoDecomp](#)<sup>5712</sup>.
- Satyaki Upadhyay, who contributed several examples to *HPX*.

<sup>5712</sup> <https://www.libgeodecomp.org/>

- Brandon Cordes, who contributed several improvements to the inspect tool.
- Harris Brakmic, who contributed an extensive build system description for building *HPX* with Visual Studio.
- Parsa Amini ([Louisiana State University \(LSU\)](#)<sup>5713</sup>), who refactored and simplified the implementation of *AGAS* in *HPX* and who works on its implementation and optimization.
- Luis Martinez de Bartolome who implemented a build system extension for *HPX* integrating it with the [Conan](#)<sup>5714</sup> C/C++ package manager.
- Vinay C Amaty (Louisiana State University (LSU)<sup>5715</sup>), who contributed to the documentation and provided some of the *HPX* examples.
- Kevin Huck and Nick Chaimov ([University of Oregon](#)<sup>5716</sup>), who contributed the integration of APEX (Autonomic Performance Environment for eXascale) with *HPX*.
- Francisco Jose Tapia, who helped with implementing the parallel sort algorithm for *HPX*.
- Patrick Diehl, who worked on implementing CUDA support for our companion library targeting GPGPUs ([HPXCL](#)<sup>5717</sup>).
- Eric Lemanissier contributed fixes to allow compilation using the MingW toolchain.
- Nidhi Makhijani who helped cleaning up some enum consistencies in *HPX* and contributed to the resource manager used in the thread scheduling subsystem. She also worked on *HPX* in the context of the Google Summer of Code 2015.
- Larry Xiao, Devang Bacharwar, Marcin Copik, and Konstantin Kronfeldner who worked on *HPX* in the context of the Google Summer of Code program 2015.
- Daniel Bourgeois ([Center for Computation and Technology \(CCT\)](#)<sup>5718</sup>) who contributed to *HPX* the implementation of several parallel algorithms (as proposed by [N4313](#)<sup>5719</sup>).
- Anuj Sharma and Christopher Bross ([Department of Computer Science 3 - Computer Architecture](#)<sup>5720</sup>), who worked on *HPX* in the context of the [Google Summer of Code](#)<sup>5721</sup> program 2014.
- Martin Stumpf ([Department of Computer Science 3 - Computer Architecture](#)<sup>5722</sup>), who rebuilt our contiguous testing infrastructure (see the [HPX Buildbot Website](#)<sup>5723</sup>). Martin is also working on [HPXCL](#)<sup>5724</sup> (mainly all work related to [OpenCL](#)<sup>5725</sup>) and implementing an *HPX* backend for [POCL](#)<sup>5726</sup>, a portable computing language solution based on [OpenCL](#)<sup>5727</sup>.
- Grant Mercer ([University of Nevada, Las Vegas](#)<sup>5728</sup>), who helped creating many of the parallel algorithms (as proposed by [N4313](#)<sup>5729</sup>).

- Diamond Howard (Louisiana State University (LSU)<sup>5730</sup>), who works on HPXCL<sup>5731</sup> (mainly all work related to CUDA<sup>5732</sup>).
- Christoph Junghans (Los Alamos National Lab), who helped making our buildsystem more portable.
- Antoine Tran Tan (Laboratoire de Recherche en Informatique, Paris), who worked on integrating HPX as a backend for NT2<sup>5733</sup>. He also contributed an implementation of an API similar to Fortran co-arrays on top of HPX.
- John Biddiscombe (Swiss National Supercomputing Centre<sup>5734</sup>), who helped with the BlueGene/Q port of HPX, implemented the parallel sort algorithm, and made several other contributions.
- Erik Schnetter (Perimeter Institute for Theoretical Physics), who greatly helped to make HPX more robust by submitting a large amount of problem reports, feature requests, and made several direct contributions.
- Mathias Gaunard (Metascale), who contributed several patches to reduce compile time warnings generated while compiling HPX.
- Andreas Buhr, who helped with improving our documentation, especially by suggesting some fixes for inconsistencies.
- Patricia Grubel (New Mexico State University<sup>5735</sup>), who contributed the description of the different HPX thread scheduler policies and is working on the performance analysis of our thread scheduling subsystem.
- Lars Viklund, whose wit, passion for testing, and love of odd architectures has been an amazing contribution to our team. He has also contributed platform specific patches for FreeBSD and MSVC12.
- Agustin Berge, who contributed patches fixing some very nasty hidden template meta-programming issues. He rewrote large parts of the API elements ensuring strict conformance with the C++ ISO Standard.
- Anton Bikineev for contributing changes to make using boost::lexical\_cast safer, he also contributed a thread safety fix to the iostreams module. He also contributed a complete rewrite of the serialization infrastructure replacing Boost.Serialization inside HPX.
- Pyry Jakkola, who contributed the Mac OS build system and build documentation on how to build HPX using Clang and libc++.
- Mario Mulansky, who created an HPX backend for his Boost.Odeint library, and who submitted several test cases allowing us to reproduce and fix problems in HPX.
- Rekha Raj, who contributed changes to the description of the Windows build instructions.
- Jeremy Kemp how worked on an HPX OpenMP backend and added regression tests.
- Alex Nagelberg for his work on implementing a C wrapper API for HPX.
- Chen Guo, helvihartmann, Nicholas Pezolano, and John West who added and improved examples in HPX.
- Joseph Kleinhenz, Markus Elfring, Kirill Kropivnyansky, Alexander Neundorf, Bryant Lam, and Alex Hirsch who improved our CMake.
- Tapasweni Pathak, Praveen Velliengiri, Jean-Loup Tastet, Michael Levine, Aalekh Nigam, HadrienG2, Prayag Verma, Islada, Alex Myczko, and Avyav Kumar who improved the documentation.
- Jayesh Badwaik, J. F. Bastien, Christoph Garth, Christopher Hinz, Brandon Kohn, Mario Lang, Maikel Nadolski, pierrele, hendrx, Dekken, woodmeister123, xaguilar, Andrew Kemp, Dylan Stark, Matthew Anderson, Jeremy
